Very compact optics were developed to provide such facilities as alternative air and surface search in the same narrow tube, as well as stadimetric range finding. A stadimeter measures the angle between the horizon and the top of an object; if the height (usually the masthead height) is known, the range can be calculated. From a submarine's point of view, the advantage of stadimetry is that the baseline is the object being measured, rather than the range-finder (which must be quite small, so as to be unobtrusive). The horizontal equivalent of stadimetry, using the observed length of the target, is impractical because most targets will not be at right angles to the line of sight of the periscope. Many attack periscopes incorporate range-only radars that supplement their optical range-finders. The alternative, particularly in optronic masts, is a laser range-finder.

There are also special night periscopes with greater light-gathering power. Some search periscopes are binocular, with duplicated windows at the top. At one time many search periscopes provided for air search, but now air warning is more usually the function of an RWR found atop the search periscope.

Two major developments are associated with the post-1945 revolution in submarine design and performance, the combination of high underwater speed and indefinite submerged periods (snorkeling when required). The first development required search and radar periscopes that could be extended at relatively high speeds (the U.S. Navy called for periscopes extendable at 14 kt). High speed in turn induced severe vibration, and images had to be specially stabilized. The second development required sextants for taking navigational fixes to be incorporated in search periscopes. Conceivably, this requirement will lose its urgency with the rise of very accurate and universally available navigational systems such as GPS, but surely the sextant will always be desirable as a backup against the destruction of the satellites.

Optronics is an outgrowth of television and FLIR technology. Periscopes were initially provided with these sensors, such as image intensifiers (LLTV), to extend their usefulness to lower light levels. However, as with surface-ship and aircraft applications, the potential of converting the image into an electromagnetic signal is much greater since the image itself can be processed. In surface or air applications, the emphasis is usually on processing for tracking. In a periscope, the emphasis is more on processing the image to extract all of its information content and even to merge it with other relevant data.

The 2 applications of such cameras are quite different. A conventional or LLTV camera can be inserted in the bottom of the periscope, taking the same image as the eyepiece, on much the same principle as a single-lens reflex camera. However, an IR sensor is best placed at the top of the periscope since thermal photons traveling all the way down the tube would suffer from added noise. Moreover, the optical components of the periscope will not focus or reflect IR radiation as they do light itself. Thus, a conventional periscope cannot be converted to IR operation by simply installing a new crosshead, whereas that periscope can relatively easily be provided with an image intensifier.

IR operation requires installation of a thermal camera at the head of the periscope. The IR sensor must be cooled, and the coolant led up a very narrow periscope tube (or else a very compact refrigerator must be incorporated in the small periscope head).

Existing optronic periscopes employ a camera analogous to the window of the periscope, fixed rigidly to a tube that the observer rotates. However, there is no reason for the observer to memorize the scene as quickly as the periscope can be turned. In principle, the sensor can make a very quick scan (or even look simultaneously in several directions), and the image can be stored either digitally or in a video recorder, for display as desired on a CRT. The newer sensors can provide images of optical periscope quality. That capability, in turn, opens up some very interesting possibilities.

The exposure associated with a periscope depends on 2 factors: the sheer size of the head and the time during which the head projects above water. Optronics probably always requires more space than simple optics, but optronics can also greatly reduce exposure time since observation need not coincide with exposure. The submarine commander can view the resulting images for a protracted time, well after they have been created. Modern digital CRTs can display these images alongside other sensor data, such as ESM data collected at the same time by the same mast. The officer viewing such a windowed CRT can fuse the data from these various sources to form a much better tactical picture. In theory, the same CRT could also display relevant sound data, again adding to the overall tactical picture in a way impossible for a conventional optical system.

Perhaps at least as important, the commander of the submarine would no longer have to be the operator of the periscope sensor, just as the commander is not the operator, but rather the supervising user, of the various other acoustic and non-acoustic sensors on board a submarine. The skipper could obtain the full tactical picture without having to concentrate all attention on the necessarily fleeting periscope image. Those manufacturers offering digital optronic or photonic periscopes, such as Dowty, Plessey, and Kollmorgen, tend to suggest radically revised arrangements for submarine control rooms or operations rooms, in 1 case with the periscope image on a large screen on 1 bulkhead, surrounded by relevant data-base readouts (e.g., the characteristics of the ship shown on the screen, to the extent that the expert computer system connected to the data can identify the contact).

An optronic sensor might also be far lighter than conventional periscope-head optics and, thus, might be much easier to stabilize and even to control in an autotrack mode.

Moreover, there is no reason why an optronic or photonic sensor must be mounted on a mast penetrating into the control room of the submarine. In some submarines, such as the German IKL designs, all masts other than the periscopes are already nonpenetrating; they telescope out of the sail of the submarine. Nonpenetration reduces structural stress in the submarine's hull and can simplify mast design since the body of the mast no longer needs to be pressure tight. Instead, most of the mast can be free-flooding. That design would allow the use of non-metallic (i.e., non-radar-reflecting) materials. Moreover, there are considerable advantages (both in drag and in radar cross section) to be gained by using a noncylindrical mast (which is acceptable if the head, rather than the entire mast, rotates).

A control room or CIC served by an optical periscope must be directly under the sail, and that requirement complicates the arrangement of the submarine. For that matter, the central position of the optical periscope greatly complicates the internal arrangement of the control room or CIC; in theory, a much more efficient arrangement is possible. Presumably, the ultimate simplification would be to eliminate the mast altogether, placing the optronics and other sensors in a towed body that the submarine could launch and recover and that would use some inertial device (such as a ring-laser gyro) to locate itself relative to the hull of the submarine. In theory, such a development would greatly reduce the drag and noise of the sub-

marine's hull, and the submarine could remain much farther below the surface at what would amount to periscope depth.

In practice, submariners have resisted total dependence on any form of electronics; an optical periscope will still work even if electrical problems have put computers and displays out of action. Attempts to eliminate the submarine's sail altogether have been quite frequent, at least in the U.S. Navy, but have generally failed because the sail is needed for some other quite essential purposes: for good depth keeping near the surface in relatively shallow water (but this requirement does not apply to a submarine with her foreplanes on her hull); for navigating on the surface (e.g., when entering port); and for supporting the snorkel.

FRANCE

◆ Pivair

This SAGEM/SOPELEM optronic periscope incorporates a CTX thermal imager usable under day and night conditions. The optical and IR channels are both biaxially stabilized. The mast-head carries an ESM antenna and the gyro-stabilized unit for both conventional optics and the IR camera. Besides the usual binocular optics, the base of the mast carries a sextant, a 35-mm camera, and the IR monitor. Optical magnification is $1.5\times$ or $6\times$ ($12\times$ optional) (FOVs: 26, 9, 4.5 deg). The angle of elevation of the FOV is $+80/-10$ deg. The FLIR operates at 8–12 micron (3×6 -deg FOV, and the same sighting angle).

SAGEM offers a range of optronic periscopes with 8–12 micron FLIRs, all of which can operate in an IR surveillance mode (360-deg scan) and all of which have biaxially stabilized optical and IR channels (so that high magnification can usefully be employed). These periscopes are insulated against vibration at high speed. The FLIRs are cooled by refrigeration (Joule-Thomson effect), and their images can be observed either by eyepiece or remotely. All periscopes incorporate both sextants and GPS receivers, the sextant data being automatically processed (using a built-in ephemeris). These periscopes can be connected so that target designation (elevation and true bearing) and range are automatically transmitted to the WCS.

These periscopes still penetrate the submarine's hull. SAGEM also offers a new generation of nonpenetrating optronic masts, each carrying a FLIR and a high-definition television, with slow automatic rotation. Both image channels are gyro-stabilized, and magnification can be controlled. The mast is pressure-proofed.

◆ SOPELEM Periscopes

Optical attack and search periscopes are manufactured by SOPELEM. The standard search periscope can incorporate a gyro-sextant, a range-only radar, and an RWR. There is generally an integral 35-mm camera (containing 250 frames of film in the case of PIVAIR, described above). Typical types are:

Attack Periscopes

ST3 for the *Daphne* class.

ST5 for the *Agosta* class. Magnifications $1.5\times$ and $6\times$ (corresponding FOVs 30 and 7 deg); elevation limits $+30/-10$ deg. The operator is provided with a seat.

Search Periscopes

M41 for the *Daphne* class.

J hull-penetrating periscope for the *Agosta* class. It incorporates the APA-4 attack-radar antenna and the AUD omnidirectional ESM antenna. Magnifications: $1.5\times$ and $6\times$ (corresponding FOVs: 20 and 5 deg).

K incorporates a light intensifier. Magnification is $5\times$, FOV 10 deg, elevation limits $+10/-10$ deg. Daylight magnifications are $1.5\times$ and $6\times$ (corresponding FOVs: 36 and 9 deg); elevation limits $+80/-10$ deg.

SOPELEM designed a special, integrated, nonpenetrating periscope system for the projected CA-class low-manning export submarine. The system is interesting because, unlike all other existing periscopes, it is integrated with other sensors and

mounted in the side of the control room rather than in the center.

The submarine has 3 nonpenetrating masts: an optical periscope, an optronic periscope, and an ESM antenna; all are contained in a single watertight chamber outside the pressure hull, with the optronic and optical masts side by side. The hull is penetrated only by electrical cables, hydraulic piping (by means of which the masts are raised), and the optical path from the optical periscope. The last is arranged so that it feeds a fixed binocular eyepiece, no matter in which direction it turns. The eyepiece is part of a console, the other side of which carries 2 CRTs for the optronic mast. Each position carries a handwheel to power-turn the mast. The advantage of this arrangement is that the periscope observer can easily compare the image with those presented optronically. Moreover, the observer is located close enough to other instruments to be able to see the consoles and other displays used for navigation. However, because the optical image is viewed only through an eyepiece, such comparison and reference cannot be direct. Nor is there any provision for windowing, i.e., for presenting several different displays simultaneously on the same CRT. That limitation probably means that the optronics is still analog rather than digital. The periscope console is still under the mast (which is off the centerline of the boat), and the console can still be viewed only at very close range.

The CA-submarine project was never sold, but its SOPELEM periscope console would seem to present an interesting intermediate point between the current conventional optical periscope, which dominates control-room arrangement, and the currently proposed pure-optronic arrangements.

◆ SSBN Periscopes

SAGEM is working on 2 periscopes for the next-generation French SSBN: a new optronic search periscope and a nonpenetrating optronic mast. The search periscope carries a thermal imager (using CCDs), and optical magnification is up to $24\times$. The companion mast carries a navigational radar, an LLLTV, a high-resolution TV, a FLIR, and an ESM sensor.

GERMANY (WEST)

◆ Series 80

Carl Zeiss optronic search and attack periscopes incorporate FLIRs, laser range-finders, and 2-axis stabilization.

UNITED KINGDOM

Barr & Stroud, a division of Pilkington Optronics, is responsible for submarine optical periscopes. Attack periscopes are desig-

(Above and left) Standard Barr & Stroud eyepieces for the 254-mm attack periscope, the 254-mm search periscope, and the 190-mm attack periscope. (Pilkington)

nated in a CH series, search periscopes in a CK series. There are 3 current types: 127-mm periscopes for small submarines (300–400 tons), which may have only 1 periscope, and 190-mm and 254-mm for larger ones. The large diameters were adopted to increase stiffness and so to reduce vibration at high speed. Existing earlier search periscope types are CH74, 75, 77, and 81; the current types are CH84, 85, and 86.

All of the current periscopes are fitted with a patented device permitting use at up to 16 kt, although 12 kt is more usual. At least in the latest search periscopes, the optics are arranged to reduce the effects of vibration by splitting the optical path at the point at which the periscope enters the submarine's sail. The standard periscope television vidicon tube is a 16-mm monochrome SIT unit.

The image intensifier available for all the current Barr & Stroud periscopes is a 50/40-mm Mullard Type xx 1332, pro-

viding a gain of up to 30,000 times. It employs an auxiliary large-aperture (110-mm, 4.3-in) window, which remains below the surface in daylight (to avoid glint). The system operates at a magnification of $6\times$ (7-deg FOV); elevation limits are $+15/-7.5$ deg. This device has been installed in Canadian *Oberon*-class submarines, and the Australian and Chilean *Oberons* are likely candidates.

As an alternative to an image intensifier, Barr & Stroud has packaged 8–13-micron-band FLIRs into its periscopes, beginning in 1978. It uses the same 110-mm window, but this time 1 made of germanium.

The standard laser range-finder is a NdYAG accurate to within 10 m, using a 10-nanosec Q-switched pulse.

◆ CH84/85/86

CH84 is the attack periscope of the *Trafalgar* and *Upholder* classes; the other 2 are related. Foreign sales include the new Australian submarines.

These periscopes often carry keypads on both sides of the binocular eyepiece so that the officer at the periscope can transmit periscope data to the FCS. The optics are quasibinocular to reduce eyestrain. These periscopes are fitted with image intensifiers (between head and eyepiece) and with laser range-finders. A television camera can be fitted in the rear of the ocular box (opposite the eyepiece), transmitting the periscope image to a remote monitor that may be connected to a video recorder. When the periscope is fitted with a FLIR, the image goes directly to the remote monitor. Relative bearing is taken from an optical encoder in the periscope crosshead, and the left eyepiece can display the corresponding true bearing. If the laser range-finder is fitted, its range data are displayed in the eyepiece. Otherwise, a stadimeter is used, and a target's range is computed automatically (given that the target's height is keyed in manually on a remote unit).

The main tube's diameter is 254 mm [10 in], with a 70-mm [about 2.75-in] upper tube; total height is about 14 m [about 46 ft]. Available magnifications are 1.5 and 6 (corresponding FOVs are 32 and 6 deg).

◆ CH99

This is a 190-mm attack periscope, which can be equipped with a thermal imager or an LLLTV camera. The FLIR is mounted at the head of the periscope, behind a separate germanium-coated window; the eyepiece carries a CRT to display the image. Magnifications are $1.5\times$ and $6\times$.

◆ CK34/35/36

These are Barr & Stroud's current standard search periscopes. CK34 is for the *Trafalgar* and *Upholder* classes; the others are modified versions. Operation is quasibinocular with 4 magnifications: $1.5\times$, $3\times$, $6\times$, and $12\times$ (FOVs: 24, 12, 6, and 3 deg). The periscope carries a sextant, the new AHPS 4 (artificial-horizon periscope sextant). This device automatically prints out the observed altitude, bearing, and time of observation. As in the case of the imager in the attack periscope (and in this one) this capability is 1 step away from complete integration with other submarine systems: the sextant could, at least in theory, feed the submarine's digital navigation subsystem directly.

As in the case of the attack periscopes, the images in the eyepiece can be captured by a television camera for display on a remote monitor. Overall tube diameter is 254 mm [10 in] and height is about 14 m [about 46 ft].

◆ CK40

This combined-purpose (search and attack) 127-mm periscope for small submarines is large enough to accommodate an image intensifier (starlight scope) and a stadimetric range-finder. Unlike the larger-diameter (binocular-eyepiece) periscopes, CK40 has a monocular eyepiece, and the line of sight is not stabilized. It lacks provisions for range conversion or transmission and cannot accommodate an ESM antenna, a television camera, or a FLIR. CK40 cannot be power-driven. There is no true bearing

scale and no digital bearing readout; CK40 has only a relative bearing scale. Like the larger-diameter Barr & Stroud periscopes, CK40 has a heated window and eyepiece and a microphone.

◆ CK59

This is the search version of the 190-mm periscope. The head is large enough to accommodate an image intensifier (starlight scope) at its head. The image intensifier can be moved into or out of the optical path. There is also provision for a FLIR. Rotation can be by power, at a speed between 0 and 12 rpm. Elevation limits: $+35/-10$ deg (up to $+74$ deg with half the FOV). FOVs at high/low magnification are 8 and 32 deg.

CK59 has all the features of the 254-mm series, except for provision for a FLIR and relative bearing readout.

◆ Optronic Masts

Barr & Stroud has developed an optronic masthead carrying a FLIR, a television camera, ESM, and communications. Diameter is about 340 mm [13.4 in] but can be reduced to 220 mm [about 8.7 in] if a reduced elevation (up to a 50-deg limit) is accepted. This masthead has been selected for the *Vanguard*-class Trident-missile submarine. In the spring of 1989 Barr & Stroud claimed that by the end of that year it would have put its optronic mast to sea on a foreign submarine.

Plessey now offers its own optronic periscope on a nonpenetrating mast originally developed for submarine communications.

◆ SSN 20 Periscope

Three teams have submitted proposals for an optronic mast for the next-generation attack submarine (SSN 20). Two are to be chosen for parallel project-definition contracts. The choice was scheduled for April 1990, but it has been delayed because of budget problems. These masts may run trials on board a diesel boat. Reportedly, the first 7 SSN 20s will have conventional optical periscopes to back up their optronic units.

The specification calls for high-definition, low-light, color TV cameras; thermal imagers; and ESM and communications antennas. The mast is to be capable of continuous rotation, with

Plessey's optronic mast, with its 2 independent sensors. (Plessey)

The Barr & Stroud (Pilkington) optronic mast, with ESM ports atop the wake-reducing fairing. (Pilkington)

a wave-following (i.e., low-wake) profile, and provide stabilized line of sight for the optronic sensors.

The teams are

- Dowty (Gresham Division)/Kollmorgen, using the latter's standard vertical head (see Model 86 in the U.S. section).

- Pilkington Optronics/Logica Space and Defense: a vertical arrangement with spiral DF antennas below the optics.

- Plessey Naval Systems: a conical ESM antenna atop an elevating cylinder with lenses side by side rather than vertically spaced. It is based on the company's communications mast, using RAM for stealth and a faired shape to avoid vibration.

The Pilkington Optronics mast shows a TV/visual window, with a thermal-imager module below it. The mast carries an omnidirectional ESM antenna at its head, and 6 DF antennas below the rotating thermal module, atop the nonrotating part of the mast. Below it is the circular de-plumer, and below that is a nonrotating fairing. The mast incorporates stabilized zoom optics, and it may employ a new Ferranti miniature video camera, using an MOS sensor, with 400-line resolution, a 28-mm lens, and zoom aperture limits of $f/2.8$ and $f/250$.

UNITED STATES

Kollmorgen and Sperry Marine manufacture all U.S. Navy periscopes. Attack submarines carry 1 attack (Type 2F, replacing Type 2D) and 1 search (Type 18 and 18B, replacing Type 15, which in turn replaced Type 8) periscope. Type 15 introduced search receivers integral with the periscope. *Permit/Sturgeon*- and early *Los Angeles*-class submarines are equipped with Type 15D. *Ohio*-class strategic submarines are unusual in carrying 2 general-purpose periscopes, Types 8L and 15L.

Unlike Barr & Stroud, the U.S. Navy did not increase periscope tube diameter to counter vibration at high speed. The U.S. approach was to build a hydrodynamic fairing around the outside of the periscope, retaining the small diameter of earlier types. This choice would have been a major advantage in the large U.S. post-1945 submarine modernization (Guppy) program.

Typical U.S. faired periscopes aboard a *Los Angeles*-class submarine off Norfolk, October 1986. (Jürg Kürsener)

◆ Type 2

The original Type 2 attack periscope was introduced in 1942. It had a long slim (1.4-in) neck and a very small head; a range-only radar, ST, was added during the war. A new Type 2D (1959) incorporated postwar advances in optical design and optical coating and is the basis of current U.S. attack periscopes. Type 2D contains a tilting head prism (elevation $+74/-10$ deg) and is bifocal, for 2 magnifications ($6\times$ and $1.5\times$; FOVs 8 and 32 deg). The stadimeter at the periscope head can be used at both powers, and the head window and eyepiece are electrically heated to avoid fogging and ice formation. A camera adapter can be fitted. Overall length is 45 ft 2.875 in (optical length 43 ft 3 in), and the outer tube diameter is 7.5 in.

◆ Type 8L Mod (T) and Type 15L Mod (T)

This combination equips *Ohio*-class strategic missile submarines, Type 8L to starboard (carrying the ST range-only radar) and Type 15L to port (carrying ESM). Elevation limits are $+60/-10$ deg, and magnifications are $1.5\times$ and $6\times$ (FOVs 32 and 8 deg). Each periscope is 46 ft long. Television camera and still-photographic camera attachments are available.

◆ Type 18

The current U.S. search periscope carries ESM intercept antennas above its gyro-stabilized optics and can provide image intensification and LLLTV for low-light operation. Train is power-assisted. There are 2 versions. Type 18B has an overall length (to top of radome) of 36 ft 10 in (optical length 36 ft from the center of the eyepiece to the zero-elevation line of sight at the prism in the head). Type 18D is 42 ft overall (optical length 41 ft 4 in). Magnifications: $1.5\times$, $6\times$, $12\times$, $24\times$ (FOVs 32, 8, 4, 2 deg). Elevation limits: $+60/-10$ deg. The LLLTV provides a 525-line format interlaced 2:1, 30 frames/sec, using a minimum of 16 gray scales; the sensor is a silicon-intensified target vidicon. Periscope functional modes are day, night, visual, TV/visual, IMC (image-motion compensated), camera, and gyro.

Sperry Marine's Type 18 Periscope ADF Group is the associated ESM system; it has been adapted to surface craft as

The eyepiece of a Trident submarine's periscope (probably Type 15L). (Kollmorgen)

The eyepiece of a Type 18 periscope, as installed on board *Los Angeles*-class submarines. (Kollmorgen)

Guardian Star (see the Antiaircraft Warfare section). It is a UYK-44-based system with a touch screen. There is no formal AN-series designator. Production is competed on an annual basis, and AEL recently won the second production lot.

Sperry Marine was selected to design Type 8J Mod 3 for the new *Seawolf*-class submarine. As of early 1991, the contract for the *Seawolf* search periscope had not yet been let.

◆ Model 76

Kollmorgen's export periscope is made in both search and attack versions; both have binocular eyepieces with split optics. Model 76 periscope ship sets are designated by separate Model numbers, e.g., 322 and 323 for the Italian *Pelosi* class (1 incorporating a laser range-finder), 324 for Italian navy *Sauros*, and 374 for Turkish Type 209s. These periscopes are also used on board the Brazilian Type 1400, the Indian Type 1500 (*Shishumar* class), and the Swedish *Nacken* class, among others.

Magnification: $1.5\times$ and $6\times$ (FOVs 32 and 8 deg); elevation limits are $+74/-10$ deg in the attack version and $+60/-10$ deg in the search version. Optics are line-of-sight stabilized. Overall diameter is 7.5 in.

The attack version carries a broad-band RWR with a display on the control unit of the periscope. The head carries a stadimeter. Optional features include a $12\times$ telescope, power rotation, a television camera feeding a remote unit (carrying a 9-in CRT), an image intensifier, a FLIR, and a video, laser, or radar range-finder. The optics can be focused down to a minimum range of 50 m.

The search version has the same powers of magnification as the attack version. Higher magnification in the form of a $2\times$ Galilean telescope (mounted in the inner structure of the mast) is available as an option. Like the attack version, the search version incorporates a stadimeter transmitting range electronically to an SFCs. The search version can carry a sextant, LF communications antennas, a satellite navigation antenna, and an ESM early-warning antenna, as well as laser and radar ranging, thermal imaging, and image intensification.

The image intensifier is mounted in the mast. In the night mode, the cube containing it is rotated 90 deg, placing the intensifier in the main optical path of the periscope and feeding the eyepiece. Typical performance, based on a ship with a vertical dimension of 10 m (a corvette), with target reflectivity of 17% is (with probability 0.85).

Illumination	Detection	Recognition	Identification
Starlight	1.5 km	0.7 km	0.5 km
Quarter Moon	2.5 km	1.3 km	1.0 km
Full Moon	4.5 km	2.4 km	1.7 km

A FLIR can be mounted between the periscope's optical head and the ESM antenna. Kollmorgen offers a serially scanned 8–12-micron SPRITE unit with a $12/4$ -deg FOV and a 0.2-mrad beamwidth. It is cooled by a split Stirling/closed-cycle refrigerator, and Kollmorgen claims that a target can be detected at 15 km, recognized at 5 km, and identified at 1.9 km.

Kollmorgen offers a television video range-finder ("stad monitor") as a complement to the television video monitor, performing split-field ranging. When the operator presses the INIT button, the image doubles vertically; the operator moves the upper image to place the mast of the lower image on the waterline of the upper one. The operator dials in the masthead height of the target, and the range is automatically computed and presented in the eyepiece.

The radar range-finder uses a slotted-waveguide antenna below the optical window of the periscope. Kollmorgen claims that the radar can be used to track surface ships. The laser range-finder is mounted in the base of the periscope, opposite the viewing optics, with a swinging mirror (as in a single-lens reflex camera) to bring its beam into the main optical path.

Kollmorgen offers a broad-band antenna with a crystal video receiver integrated into the top of the attack periscope head, with omnidirectional coverage (2–18 GHz, sensitivity -35

dBm). Indication is by LED (band, CW, or pulse) and audio alarm, the indicators being mounted on the periscope crosshead. Alternatively, a more elaborate (and more massive) ESM/DF antenna can be mounted in the head of the periscope, covering the same frequency range but providing either quadrant or 10-deg directional accuracy. This system can connect to other submarine systems.

The sextant uses the periscope synchro to read off its line of elevation from the deck plane, the target-bearing transmitter to measure the target's direction relative to the submarine, and a built-in vertical reference to determine tilt and cross tilt angles so that the sextant can measure star altitudes relative to the true horizon. The corrected altitude angle, bearing angle, and time are displayed and printed.

The basic periscope can also be fitted with a microphone, allowing the user to communicate with other parts of the submarine while making observations.

◆ Model 86

Model 86 is the nonpenetrating 2-stage optronic mast currently under development by Kollmorgen. There are 2 windows arranged vertically, 1 for television, and below it 1 for a FLIR. The main television sensor is a color CCD, but prisms can direct the optical path down to a light-intensifier. A mirror behind the FLIR window directs the thermal path down the axis of the periscope to a thermal camera. The entire photonic system is

2-axis stabilized. The CCD television camera has 3 FOVs, 22.8, 10, and 4.4 deg; elevation limits are +74/-10 deg. The 8-element SPRITE FLIR system has 2 FOVs (2 magnifications), 10 and 4.4 deg; elevation limits are +55/-10 deg. It operates at 8-12 microns (with 3-5 micron operation an alternative option). The head should be capable of a sector scan in less than 2 sec, and a full scan in 5 or 6 sec (or less using a black-and-white camera). Kollmorgen expected to evaluate a new color CCD camera for the U.S. Navy early in 1990. The ESM coverage requirement depends on the customer but is typically 1-40 GHz, with a DF accuracy of 5 deg, and with threat analysis and identification. The ESM head can also accommodate a GPS antenna.

Late in February 1989 Kollmorgen announced a joint venture with Riva Calzoni of Italy to develop a new generation of nonpenetrating mast and sensor systems for future submarines. Riva Calzoni has supplied numerous nonpenetrating masts, both to the Italian navy and to other NATO and non-NATO navies, since 1967. The head of the Riva Calzoni-Kollmorgen periscope will be based on that of the Kollmorgen Model 86. The mast is a new 2-stage type based on the current Riva Calzoni 1-stage nonpenetrating mast. Video connections would be by fiber optics (work is proceeding on a rotary fiber-optic joint), and there would be no waveguide connections (the ESM sensor may use a copper cable; in future, the ESM array may digitize its data at the masthead and send it down in optical form).

The U.S. version of the periscope will use a Raytheon or Singer Librascope console; the Italian version will use the Selenia MAGICS console.

An artist's concept of a next-generation submarine control and imaging center, fed by a nonpenetrating optronic periscope. (Kollmorgen)

(Above and right) Kollmorgen's Model 86 nonpenetrating periscope. (Kollmorgen)

◆ Other Optronic Periscopes

The U.S. Navy does not currently use any optronic periscopes. However, in recent years there has been considerable interest in the subject. An R&D (technical demonstration) optronic-scope project, Dark Eyes, was begun about 1979 and was tested at sea but never entered production, and by about 1984 Dark Eyes had been retired. Dark Eyes suffered because it was a special-purpose system (limited to the 8–12-micron band) and because installation in the sail of a submarine proved extremely expensive. It did employ a nonpenetrating mast.

The broader-spectrum optronic ("photonic") concept is now being pursued. An experimental electro-optical periscope image-storage system is operational at NUSC New London. About 1985 the U.S. SSN 21 (*Seawolf*) program became interested in a nonpenetrating photonic mast. A research program, begun in 1986 under navy auspices, was soon taken over by DARPA, the latter awarding Kollmorgen a \$3.5 million prototype contract early in 1989. This prototype was to be installed on board the experimental submarine *Memphis* early in 1990.

Early in February 1989 Dowty (of the U.K.) announced a collaborative venture with Kollmorgen to develop optronic replacements for existing Royal Navy (and, later, other) optical periscopes. Dowty described the joint venture as a combination of Kollmorgen's electro-optical skills with its own command, control, and display expertise. In this case the mast would also be nonpenetrating, its head carrying both optical and IR cameras. Images would be transmitted into the hull by fiber-optic cable.

The DARPA, Riva Calzoni (Model 86), and Dowty projects are all separate. DARPA and Dowty are concentrating on the

requirements of, respectively, the U.S. and Royal Navies, whereas the Riva Calzoni project is for wider commercial application. Prior to these announcements, Kollmorgen had advocated optronic nonpenetrating periscopes for some considerable time, publicly at least since 1986.

SONOBUOYS AND AIRBORNE SIGNAL PROCESSORS

Most Free World sonobuoys are built to a standard "A"-size ($4\frac{7}{8}$ in $\times$ 36 in) to fit the buoy ejectors of such aircraft as the Nimrod, P-3 Orion, and Atlantique. "B"-size is $6\frac{7}{8}$ $\times$ 60 in (ERAPS size); "C"-size (9 in $\times$ 60 in) was used only by Britain; and "D"-size is 3 in $\times$ 15 in (projected for submarine underwater signals). "E"-size probably refers to a projected D-size sonobuoy. "F" is a dwarf (A/3) size ($4\frac{7}{8}$ $\times$ 12 in) now used by the Royal Navy and for some French buoys. The U.S. Navy is considering an A/2 size ($4\frac{7}{8}$ $\times$ 16.5 in), which may be designated "F." "G" is A/2 size ($4\frac{7}{8}$ $\times$ 18 in), but it was discarded because a filler was needed between 2 buoys in a launch tube: hence the choice of the 16.5-in length.

In 1973 the Space Development Corp. announced that it had developed a smaller-diameter (conventional length) equivalent

of SSQ-41, several of which could be loaded side by side into a standard A-store tube and which, therefore, could be launched in any order, unlike Dwarfs. See the entry for SSQ-41 below.

The other major factor in sonobuoy operations is the number of available radio channels (for the link with the airplane), typically either 31 or 99. As sonobuoy range decreases because of submarine quieting, the number that must be laid to gain contact (or to search an area) increases; therefore, more channels are needed. About 1984 the major improvement was the increase from 31 to 99, as reflected (in the U.S. Navy, for example) by replacement of the 31-channel ARR-72 receiver with the 99-channel ARR-78.

In these notes, LOFAR (low-frequency analysis and recording) is spectral analysis using time integration to pick up stable narrow-band signals amid the surrounding noise. CODAR is a correlation-display analyzing recorder, which measures the time difference between reception of the same signal by 2 buoys. As in the PUFFS passive ranger for submarine fire control, CODAR can obtain the direction of a signal relative to the 2-point hydrophones that pick it up, given knowledge of the spacing of the buoys (which were dropped at specified points by intervalometer). If the time of the signal's origination is known, CODAR also gives a range. The system of dropping a signal depth charge and then using CODAR to pick up the echoes of the explosion off a submarine is code-named Julie. Originally Julie was developed by the U.S. Navy as a way of using existing

passive buoys despite silencing of Soviet submarines in the late 1950s. (Reportedly the name Julie honored a stripper who could "make a passive buoy active.") It was largely abandoned in favor of a new passive technology, LOFAR (code-named Jezebel). The necessary signal-processing technology has survived, however, and Julie probably has not been altogether abandoned.

A LOFAR buoy differs from other passive buoys in that it has a narrow frequency range since the processor will concentrate on frequencies around the particular line of interest. Signals within the prefiltered narrow range will be transmitted very precisely, for further analysis on board the airplane. The buoy behaves much like a crystal-video ESM receiver, limiting its response to a zone of interest but not providing precise data within that zone. Although a submarine may emit strongly at only a very few frequencies, acoustic conditions on a given day may make it easier to detect some harmonic of 1 of those lines. Typically, then, a searching airplane drops XBT and background noise buoys, and then the LOFAR buoys are set for the line sought. Thus, although a LOFAR buoy may have a frequency spectrum of many octaves, in practice it is set for a much narrower range of frequencies; the actual range (which is related to the precision of the processor) is classified. A LOFAR-CODAR buoy can be set for either narrow or broad frequency range operation.

DIFAR is directional LOFAR. A DIFAR buoy has 2 beam patterns, at right angles to each other; it, therefore, measures 2 components of the signal it detects. It sends 2 LOFAR signals (corresponding to its 2 beams) up to the monitoring airplane, plus a sense signal to resolve the 180-deg ambiguity in the 2 beams. Thus, from a signal-processing point of view, 1 DIFAR buoy equals 2 LOFAR buoys. Signal processing includes comparison of the 2 signals, generally using an arctan function to derive an angle. The resulting direction is not precise because the 2 beams overlap to a limited extent, but target direction can generally be found within about 10 or 15 deg.

There are also command-activated pinging buoys, either omnidirectional (range-only, or RO, also called CASS, for command-activated sonobuoy system) or directional (e.g., the U.S. DICASS and the British CAMBS). Typically, active CW is used to measure target speed (doppler). FM pulses (equivalent to pulse compression in radar) are used for range resolution. Typically, the pulse length can be varied by command; a longer pulse gives longer maximum range but can suffer from reverberation.

Sonobuoys require a number of settings. When they are launched from within an airplane's pressure cabin (as in the British Nimrod, for example), the crew sets them at launch time. The U.S. P-3C carries them externally, in sonobuoy

B-size Stretch A A-size G-size F-size A/6
The range of sonobuoy sizes. (Sparton)

Standard A-size sonobuoys being loaded. The vanes protruding from their heads are rotochutes, which slow the buoys as they descend. (U.S. Navy)

launch containers (SLCs) set before flight time. If the launchers are inside the pressure cabin, then the cabin must be depressurized if multiple buoys are to be launched (the Nimrod uses a 6-rnd launcher) or else launched 1 by 1 through a special pressurized launcher. An airplane intended to launch buoys from high altitude (e.g., while monitoring a large field) must almost inevitably use external launchers.

In the case of the P-3C, the aircraft tactical system is aware of which buoys are set in which way and selects the ones it wants. This method becomes less satisfactory as the number required to prosecute a contact grows toward the total on board, and as the buoys themselves become more flexible in their operation (so that setting involves more tactical judgment, made at the scene of prosecution). The 2 available solutions are a command down-link and remote setting on board the airplane.

AUSTRALIA

SONOBUOYS

◆ Barra (SSQ-801/SSQ-981)

Barra is an A-size (914 mm × 123.8 mm, 12.7 kg) broad-band (10–2000 Hz) array sonobuoy, employing 25 hydrophones in a horizontal configuration (planar array consisting of 5 outstretched arms). The 60 beams formed by the array can be steered horizontally, and bearing data are provided by an internal magnetic compass. Because the beams can be quite narrow, the manufacturer, Sonobuoys Australia, claims that a single Barra can provide detection, classification, and unambiguous bearing information. Two units should, therefore, provide rapid passive localization.

Array depth is either 21.5 or 128.5 m, and operating life is 0.5, 1, 2, or 4.5 hr. Fifty VHF channels are available; data are transmitted at 136–173.5 MHz (channels are spaced 0.750 MHz apart), the data-sampling rate being 8.29630 kHz.

Processing is done by either an AQS-901 (RAAF Orion or RAF Nimrod) or the combination of a UYS-503 sonobuoy processor and an AQA-801 side processor in a helicopter (RAN Sea Hawk).

SSQ-981 is a version for the U.K. MoD, developed by Plessey, which claims that its manufacturing techniques reduce unit cost. Dimensions match those of the original SSQ-801, but weight is reduced to 11 kg. Alternatives for the operational life span are 1, 2, 3, or 4 hr, and the operating depth is 21.5 or 121 m.

BARRA sonobuoy. (Plessey)

BARRA array deployed underwater, looking down. (Plessey)

Compass resolution is 0.36 deg, and accuracy is 1.0 deg at less than 65 deg in latitude. At least in the case of the Plessey version, the airborne processor forms 60 beams.

The program began in 1969 as Project Barra, full development being approved late in 1974. Initial production was completed by Amalgamated Wireless late in 1981.

The Barra production rate for the Royal Australian Navy in 1981–89 was 2000/yr, but as of 1989, it was rising to 2500/yr, to provide for exports to the Royal Navy. By 1989 a total of more than 30,000 had been manufactured.

Sonobuoys Australia is now developing a variant of Barra (E Barra, i.e., E-sized Barra) with a VLSI in-buoy processor, allowing it to operate without a dedicated Barra airborne acoustic processor. The same in-buoy processor also forms part of a completely new buoy, as yet unnamed, that the company is developing under a contract from the Australian Defense Science and Technology Organization (DSTO).

CANADA

SONOBUOYS

◆ SSQ-512 and -520

Julie buoys (for explosive echo ranging) are A-size, with a lifetime of $\frac{1}{2}$ hr or $1\frac{1}{2}$ hr. The hydrophone depth is 60 or 600 ft, and the buoys have 31 radio channels.

◆ SSQ-517 and -518

These passive A-size LOFAR/CODAR buoys operate omnidirectionally (10 Hz–10 kHz). SSQ-517A has a lifetime of 1 or 3 hr; -517B lasts $\frac{1}{2}$ hr or $2\frac{1}{2}$ hr. Both have a hydrophone depth of 100 ft. SSQ-518 and -518A are much longer lived, respectively, $13\frac{1}{2}$ and 8 hr. All report on 1 of 31 radio channels.

◆ SSQ-519 and -521

These passive A-size LOFAR/CODAR buoys are for ships' use; SSQ-521 has a 13.5-hr lifetime, -519 over $2\frac{1}{2}$ hr. Hydrophone depth is 100 ft. Reporting is on 1 of 31 channels.

◆ SSQ-522

This active range-only buoy, manufactured by Sparton of Canada, Ltd., is equivalent to the U.S. SSQ-47B. More than 175,000 had been delivered by FY85, and production was proceeding at 5000–7000 per year for export. SSQ-522 is license-manufactured in Japan, Norway, and the United Kingdom; and the buoy is also used by Italy, the Netherlands, South Korea, Spain, and Taiwan (GOC).

Lifetime is $\frac{1}{2}$ hr, with the hydrophone at 80 or 600 ft, and

there are 12 radio channels. Acoustic frequencies are 13.0, 14.2, 15.4, 16.6, 17.8, and 19.0 kHz.

◆ SSQ-523

The CANCESS command-activated sonobuoy has 6 HF sonar channels (short, medium, long CW pulses, linear FM sweeps) and is controlled by a 12-channel UHF radio. Dimensions are 5 in × 3 ft. Depth is 60 or 800 ft. Sparton received a contract for an enhanced version in 1973, and 20,000 were ordered through 1986.

This buoy is roughly equivalent to the U.S. SSQ-50.

◆ SSQ-525

SSQ-525 is the Canadian equivalent of the U.S. SSQ-77 VLAD.

◆ SSQ-527 A/B

This passive omnidirectional A-size buoy is manufactured by Sparton of Canada. Weight is 21 lb, and hydrophone depth is selectable (98, 328, or 984 ft), with a lifetime of 1, 3, or 8 hr. The buoy uses 31 RF channels.

These buoys are equivalent to the U.S. SSQ-41B.

◆ SSQ-530

This passive directional LOFAR buoy (DIFAR), made by Sparton of Canada, is equivalent to the U.S. SSQ-53B.

◆ SSQ-531

This passive line-array directional buoy is made by Sparton of Canada.

◆ Microbuoys

In parallel with the U.S. LCS program, the Canadian DREA (Defense Research Establishment Atlantic) has been conducting a microbuoy program since 1983. It seeks buoys small enough to be carried by RPVs and by light aircraft. The initial goal was an A/20 buoy, which would be individually launched from an A-size launch container.

The manufacturers are Sparton and Hermes, and the buoys are fully programmable omnidirectional LOFARs. They were test-dropped by an Aurora maritime-patrol aircraft in the fall of 1988. An A-size container held 12 Hermes or 16 Sparton buoys. The Hermes shape resembles a hockey puck and transmits real-time data by frequency-sharing a standard channel with the other microbuoys. Sparton's is relatively long and slender with wedge-shaped cross section. It transmits intermittently in burst form (time-sharing sequentially). Both use a novel ejection scheme. The inflation of the surface float forces the buoy from the container with sufficient velocity to clear the slipstream; the float itself then slows descent.

The emphasis on use by an RPV or light aircraft, i.e., by a vehicle not designed for ASW, requires that the buoy do more of the work. In the Canadian case, the buoy incorporates an FFT spectrum analyzer, so it sends, not raw acoustic data, but rather spectral data. These data are digitized, compressed, and burst-transmitted to the aircraft; the system uses time-division multiplexing so that all buoys from 1 launch can share the same radio channel. These buoys deployed down only to 100 ft since cable space within them was limited.

As of 1989, both contractors planned to enlarge their buoys to A/6 size for better performance; they will be able to suspend their hydrophones to 1000 ft and also operate at lower frequencies.

As of 1989, it was not clear whether DREA would continue to fund this work or whether the contractors would seek U.S. funding under the ELCS/ILCS program (see LCS, below).

The original program goal was to package a usable LOFAR buoy in A/20 size. Sparton developed such a Microbuoy in 1984; it was wedge-shaped and 18 cm high, so 5 stacks of 4 each could fit inside a standard A-size container. Sparton also pursued a Miniature (A/12) LOFAR-buoy program, transmitting real-time or processed data (as commanded by a UHF channel). It is 28 cm tall, and performance is comparable to that of SSQ-41B in

low sea-states. Sparton developed a variety of seeder magazines for its small buoys.

SIGNAL PROCESSORS

◆ UYS-502

Emerson Electric's CALYPSO (computerized acoustic analyzer processor) sonobuoy processor is for Canadian CH-124 (Sea King) helicopters. It has 32 time-multiplexed channels and uses parallel multiple arithmetic units for pulse compression, digital translation and filtering, FFT, display scaling, and other post-processing functions.

◆ UYS-503

Computing Devices Co.'s airborne signal processor is used by Australia, Canada, Sweden, and the United States. UYS-503 uses denser memory components than its predecessors. This processor suffices for all buoys except the complex broad-band Barra; that buoy requires a Side Barra Processor, SBP 1-1. This combination is part of the Australian RAWS (role-adaptable weapons system) of the Seahawk helicopter.

UYS-503 stores 20 min of LOFAR data from each buoy (4 DIFAR or 8 omnidirectional) in 4 modules (1 unit). Alternatively, each module can be used with 1 DICASS or 1 range-only buoy (the former with CW or FM pulses, the latter CW only). UYS-503 can also process expendable bathythermograph buoys or a dipping sonar (1 "slice" per 90-deg sector). Each 44-lb unit includes 8 standard buoy receivers.

UYS-503 and AQS-902G were tested in April 1987 as alternative processors for the SH-2F LAMPS-I helicopter; there was no U.S.-produced alternative. Late in 1988 UYS-503 was selected for new-production SH-2G helicopters. It will be installed on board existing SH-2Fs as they go through a SLEP program. The stated reasons for the preference for UYS-503 were its signal-detection performance and its better bearing accuracy (when working with DIFAR buoys). Both presumably reflect faster arithmetic. Better signal detection would be achieved by quicker calculation of FFTs with better frequency resolution (i.e., using more points). Better directionality would mean more accurate comparison of the 2 DIFAR-buoy beams, which again is a matter of more precise arithmetic.

In an SH-2G, UYS-503 is integrated with the ASN-150 tactical system by a CDC Interface Converter Unit (ICU). The ASN-150 multifunction display can show both radar and sonobuoy video. UYS-503 is also the basis of the Canadian HAPS (Helicopter Acoustic Processing System) for the new EH-101 helicopter; it uses 2 UYS-503 to handle 8 DIFAR, 16 LOFAR, or a combination of the 2, plus the Cormorant LF dipping sonar.

UYS-503 has been selected as the sonar processor of the new Swedish *Göteborg*-class corvettes. It is also the processor of the Canadian SQS-510 sonar and of the SQR-501 towed array. UYS-503 has also been selected to equip the Fokker Maritime Enforcer Mk 2.

Computing Devices Co. was formerly Computing Devices of Canada.

◆ HIPADS/HAPS

Helicopter integrated processing-and-display system/helicopter acoustic processing system is the Canadian next-generation sonobuoy processing system. HIPADS is being developed by Canadian Marconi, Computing Devices Co., and Litton Canada. HAPS is being developed by Computing Devices Co. and uses the Plessey Cormorant dipping sonar.

◆ SBP 1-1

The Barra processor works with the UYS-503 processor. SBP 1-1 can also function as a stand-alone processor, consisting of 4 subprocessors. Each subprocessor can handle 8 omnidirectional buoys or 4 DIFAR or DICASS. In the passive mode, SBP stores 20 min of LOFAR data on each frequency channel; the operator can call up and display the stored data on the CRT. The unit includes a patented demultiplexer that allows digital

sonobuoys to be used with a standard analog receiver. A second SBP 1-1 can be connected in parallel to double the processing capacity.

The first SBP 1-1 was delivered in the summer of 1984, and the unit was bought for Canada and Sweden (and for Australia, in conjunction with a UYS-503).

The Barra Side Processor has been sold to the U.S. Navy for the P-3Cs of the specialist Beartrap squadron. It operates with the usual UYS-1. UYS-503s have been installed for evaluation on board the same aircraft.

FRANCE

As of 1989, the French navy was evaluating a system comparable to the U.S. LAMPS I, i.e., a helicopter dispensing buoys but transmitting their output back to the ship for processing. The Lynx helicopter would carry an Alkan pod launcher, with 18 F- or G-size buoys.

SONOBUOYS

◆ DSTA-3

CIT-Alcatel's active buoy operates at depths of 65 or 330 ft; it transmits at 9, 10, or 11 kHz and reports on 1 of 16 radio channels. DSTA-3 works with a DSAA-4 processor, which can handle 2 buoys simultaneously.

Development began in the late 1950s, with trials in the mid-1960s and service in 1968-70. There were large orders in the 1970s and early 1980s, and later buoys were modified for better sensitivity. Reported production through 1986 was 15,000. The current version is DSTA-3E (123 mm × 914 mm, 16 kg, depth 30 or 135 m, 4 sonar and 8 VHF channels, lifetime about 20 min).

◆ DSTV-4L/M (MSR-810) (TSM 8010)

Thomson-CSF's passive buoy (124 × 914 mm, 8 kg or less) is also produced in Italy by Misar as MSR-810. DSTV-4L, the passive counterpart to DSTA-3, operates at 65 or 330 ft (with an additional 990-ft option in the -4M version), is omnidirectional (10 Hz-20 kHz), and has a lifetime of 1, 3, or 8 hr. DSTV-4L/M reports on 1 of 31 radio channels. The -4M version is more reliable and more sensitive.

DSTV-4L was developed in the early 1960s, trials following in the late 1960s. The -4L version was procured in 1963 and 1968.

This buoy, which replaced DSTV-2K, is broadly equivalent to the U.S. SSQ-41A/B.

As of mid-1989, Thomson had delivered more than 130,000 TSM 8010 (DSTV-4M) buoys to the French navy and export customers. MISAR (Italy) has a license-production agreement.

◆ DSTV-4N

This ambient-noise measurement buoy is analogous to the U.S. SSQ-57.

◆ DSTV-7 (TSM 8030)

An A/3-size (124 × 305 mm, 4 kg) version of DSTV-4M, DSTV-7 incorporates a radio-frequency synthesizer so that buoy radio channels need not be set before flight. Instead, they can be set manually on the airplane from among a preselected 34 of the total of 99 channels, separated by 375 Hz, ranging from 136-173 MHz. Frequency range of the buoy is 10 Hz-20 kHz (optimally 5 Hz-20 kHz); the hydrophone depth is 20 or 100 m (with an optional 300-m setting). Lifetime is 1, 3, or 8 hr. The buoy can be dropped from 150-10,000 ft, at 80-250 kt.

DSTV-7 is probably a LOFAR buoy. It entered production in 1986. In 1986 the French navy decided to develop a DIFAR buoy.

As of mid-1989, 30,000-40,000 TSM 8030 (DSTV-7A) had been made.

◆ TSM 8040

Thomson Sintra's A-size (124 × 915 mm, 17.6 kg) DICASS buoy operates at 6.5, 7.5, or 9.5 kHz with either CW pulses (0.1-0.5

Standard French sonobuoys: DSTV-4M at left, the A/3-size DSTV-7B in the middle, and a range-only active buoy at right. The buoy on the left shows the rotochute that slows its descent. The other 2 show the inflated floats that keep their radio antennas above the surface. (Thomson Sintra)

DSTV-7X mini-Jezebel (LOFAR) buoy. (Thomson-CSF)

Components of a Thomson DSTV-7 omnidirectional buoy (A/3 = size). (Thomson Sintra)

or 1 sec) or 1-sec FM pulses; pulses can repeat with intervals of less than 1 sec. Beam modes are ODT, cosine, or sine. Depth, remotely selectable, is 20 m or 150 m (450 m optional). The buoy reports on 1 of 31 VHF channels, and it is controlled by UHF (291.4 MHz). Power is supplied by a lithium cell, with an operational life of 30 min at 20 m, 20 min at maximum depth (50 sec of emission).

Production began in 1986.

◆ TSM 8050

Thomson Sintra's A-size range-only buoy entered production in 1989. Weight is 17.69 kg. Acoustic frequency is 6.0, 6.71, 7.5, 8.4, 9.4, or 10.5 kHz. The buoy emits either CW pulses (4 pulses in a train, total duration 100 msec) or FM pulses (1 pulse lasting 320 msec), in each case with an 11-sec recurrence rate. The hydrophone is at a depth of 20 or 150 m (TSM 8050A) or at 20 or 450 m (TSM 8050B). Total operational life is 30 min, using a lithium cell and a magnesium/lead-chloride battery. The buoy reports to the launching aircraft by VHF on 1 of 12 possible channels spaced 750 kHz apart (162.25–170.50 MHz), at a power level of 0.25 W (compared to 1 W for the passive DSTV-7). Presumably the lower power level corresponds to the planned tac-

Components of a Thomson TSM 8050 range-only buoy, showing its parachute, its electronics, and its transducer. (Thomson Sintra)

tical use of the buoy, as a means of localizing a submarine detected by a relatively large field of passive buoys (some of which might have to be monitored from a considerable distance).

◆ TSM 8060

This family of G-size DIFAR buoys is under development; all major components are tailored to a future F-size version.

◆ Low Cost Buoy

As of 1986, Thomson-CSF was beginning work on a future low-cost sonobuoy, presumably comparable to the U.S. LCS.

SIGNAL PROCESSORS

◆ DSAX 1 (SADANG, TSM 8210)

Sadang 1000, a lightweight acoustic processor for small maritime-patrol aircraft. (Thomson Sintra)

DSAX 1 is the signal processor of the Atlantique-2 maritime-patrol aircraft. SADANG means *Système Acoustique de l'Atlantique Nouvelle Génération*. This system is oriented toward processing omnidirectional buoys. It has 2 operators and can process 16 sonobuoys simultaneously (each processor has 8 LOFAR channels, equivalent to 2 DIFAR channels). Processing capability includes DEMON (recovery of LF lines by demodulating broad-band noise). This processor uses CODAR (discrepancies in amplitude, frequency, time, or phase between 2 or more buoys) to determine lines of bearing and range.

TSM 8210, the export version, is lighter and has 1 processor and 1 operator. Total weight is about 140 kg.

◆ TSM 8200 (SECBAT)

Thomson Sintra's airborne signal processor for the Atlantic-1 works with active or passive buoys, with ambient-noise buoys, and with XBTs. TSM 8200 uses a 99-channel VHF receiver and a UHF transceiver for active-buoy control. There are 2 operators.

◆ TSM 8220 (Lamparo)

Thomson Sintra's acoustic-signal processor for small maritime-patrol aircraft or helicopters is derived from DSAX 1. Lamparo employs 1 operator and can simultaneously process 4 or 8 sonobuoys. This processor can also be integrated with an HS 12 dipping sonar. Processing techniques are LOFAR, CODAR, DEMON, and range-only. TSM 8230 is a modified version that can support a dipping sonar as well as sonobuoys.

Lamparo has been adapted to the AS 332F Super Puma and to the AS 365F Dauphin-2 helicopter (as in the Saudi frigates). It can also be carried by small maritime-patrol aircraft. Brazil bought it for installation on board 20 EMBRAER Bandeirantes (10 more are on order), and it has probably also been installed on board up to 9 Chilean aircraft of this type. Lamparo may also have been installed on board the 8 modernized Brazilian S-2 Trackers. If in fact China bought HS 312 (as opposed to HS 12) for its Zhi-8 helicopters, then China, too, operates Lamparo.

A new system is under development as part of FLASH (Flexible Lightweight Acoustic System for Helicopters).

Lamparo LOFARgram display. The curved white area is a reflection from the pilot's helmet; the display proper shows the usual vertical lines, spread out over the frequency spectrum. The operator seeks lines that remain stable over time. (Thomson Sintra)

INDIA

In 1978 Hindustan Aeronautics, Ltd., reported that it was producing a sonobuoy for the Indian navy, based on a design by the Naval Physical Oceanographic Laboratory at Cochin. The buoy is retarded by rotochute, and it lowers its transducer to a depth of 30 m. Lifetime is 8½ hr, power being provided by a nickel-cadmium battery; and data are transmitted by VHF (162.25–172.5 MHz). Presumably, the buoy is A-size, to fit Western-supplied helicopters and aircraft, and its long life suggests fully passive operation.

India is currently developing an Advanced Light Helicopter which is to be built in separate sonobuoy and dipping sonar versions.

ITALY

◆ BI Series

The BI series are Olivetti's buoys. BIT-3 is a 5 in × 36 in omnidirectional buoy, operating on 31 channels, at 65 or 330 ft; lifetime is 1–3 hr. BIT-8 is similar but adds 10 more channels. BIR is intended for light helicopters (4.5 in × 24 in, 1-hr lifetime, 65-ft maximum depth).

Work on these buoys began in the mid-1970s to replace U.S. types. After trials in the late 1970s the buoys entered service in 1979–80; about 12,000 were manufactured through 1986. They were intended specifically for the Mediterranean, with its shallow surface layer.

An earlier Julie-Jezebel buoy, BI 68, was announced about 1974. Dimensions were 91 × 1220 mm (weight 8 kg), and the manufacturer, USEA, claimed that BI 68 could operate on twice the usual number of channels. Maximum depth was 60 m. Presumably, this buoy never entered service.

◆ MSR 810/910

MSR 810 is a license-produced version of the French DSTV-4L/M LOFAR buoy. Misar is currently developing MSR 910, a range-only active buoy.

JAPAN

◆ HQS-3D

Japanese Julie (explosive echo-ranging) buoy, manufactured by Oki, is equivalent to the U.S. SSQ-23.

◆ HQS-5

This BT buoy is equivalent to the U.S. SSQ-36. HQS-5D operates down to 1500-ft depth, and -5E down to 4000 ft.

◆ HQS-6B

Oki's LOFAR buoy is equivalent to the U.S. SSQ-41.

◆ HQS-12

Oki's DIFAR buoy is equivalent to the U.S. SSQ-53.

◆ HQS-21B

Oki's acoustic-reference buoy is equivalent to the U.S. SSQ-57.

◆ HQS-31

NEC's active buoy is equivalent to the U.S. SSQ-47.

◆ HQS-32

NEC's active buoy is equivalent to the U.S. SSQ-50 CASS (omnidirectional).

SWEDEN

The Royal Swedish Navy uses moored sonobuoys, deployed from specialized surface craft, as mobile hydrophone arrays. The buoys are locally manufactured but are descended from about 50 Dowty buoys purchased several years ago.

USSR

It is very unlikely that the following catalog is complete; rather, it is an indication of past progress and of past design practice. Soviet warships are equipped to receive sonobuoy data.

According to a Soviet book on helicopter ASW (1985), helicopters typically drop sonobuoys in pairs, from the lowest possible altitude, across or near the expected target track. At least at the time of publication, Soviet doctrine was to use sonobuoys only in bad weather, when helicopters could not use their dipping sonars. Reportedly, of all current Soviet ASW helicopters, only Helix A has full all-weather and night capability. Other types require a horizontal visibility of at least 50 m.

Sonobuoys are typically dropped across or near the expected target track, at variable depths. Soviet publications describe square and circular sector barriers, the latter to be used when more time is available. Active sonobuoy range is reportedly 1850–5550 m, and passive range is about 10,000 m.

These tactics and ranges are reminiscent of Western pre-LOFAR practice, the buoys being used primarily for target prosecution rather than for search. Presumably, the appearance of Soviet LOFAR buoys (Type 75, see below) will radically change tactics, but only for platforms equipped with the appropriate processors. It is possible that only Bear-Fs are so fitted, and indeed that Bear F was introduced as part of a LOFAR system.

Land-based helicopters, such as those used by the East Germans, typically form 2-helicopter (search and attack) teams, the search helicopter doing post-attack assessment. Again, such practice is reminiscent of earlier Western practice, preceding the appearance of single-package ASW helicopters and aircraft. It may also be required by the great weight of Soviet homing torpedoes. The preferred helicopter-borne weapon is reportedly the homing torpedo, depth bombs being used only against surfaced or periscope-depth targets. There is also a nuclear depth bomb.

◆ RGB-56/64

RGB-56/64 were the first Soviet sonobuoys, the numbers presumably indicating dates of design. RGB-64 (6 × 37 in, 33 lb) was a somewhat miniaturized version of RGB-56 (which was approximately 8.75 × 48 in, with a total weight of 60 lb). Both buoys are omnidirectional, with detection ranges of about 2000–4000 yd. RGB-56 operates over the 4.4–6.4 kHz range; RGB-64 operates between 3 and 11.5 kHz. The data link is 18-channel AM (49.2–53.45 MHz), each buoy being preset before launch.

RGB-56 was first seen in September 1959. It was dropped at low altitude (500–1000 ft) and low speed (150 kt) and was par-

achute-retarded (lanyard activated). This procedure helped avoid drift. The hydrophone's beam was 17 deg wide in the vertical.

In each case, the buoy does not transmit unless target noise (in effect, integrated over its bandwidth) exceeds 1 of 7 (RGB-56) preset threshold levels. The monitoring helicopter, therefore, continuously tunes over the 18 channels, automatically locking onto a transmitting buoy and locating it using a VHF/DF built into the sonobuoy receiver. The operator can listen, e.g., for a turn count, and then resume tuning or can hand-tune. The operator can obtain a rough fix by comparative listening, or try to estimate a submarine's speed by turn-counting.

The threshold procedure also extends the buoy's life, which (in RGB-56) could be as great as 4 to 5 days (given battery strength; the buoy was designed, however, to scuttle in 24 hr).

U.S. observers compared RGB-56 with the first U.S. postwar broad-band buoy, SSQ-2, and also noted that RGB-56 had the beam pattern appropriate to bistatic operation with an active sonar, the transmission biasing necessary to prevent transient interference, and the center frequency (5 kHz) and band pass well suited to such operation. Presumably, the wider bandwidth of RGB-64 showed that the Soviets did not intend to use their buoys that way, at least at the time.

There were also marker buoys (RBM-100 and -200).

By 1962 U.S. naval intelligence was reporting that the Soviets had stated a requirement for a directional buoy to replace RGB-56. RGB-56 components had appeared, by that time, in a variety of old mine, buoy, and paravane casings, presumably to monitor U.S. and NATO exercises.

◆ BM-1

This passive omnidirectional sonobuoy was manufactured about 1966–70. BM-1 uses a line hydrophone. Dimensions are 6 in × 50.5 in. The 29-channel FM-radio data link is at about 171 MHz (channels separated by 150-kHz intervals). Internally,

Standard Soviet sonobuoys: 3 RGM (RGB-56) on the left, RGBN (RG-64) on the right. All are still in use. (U.S. Navy)

BM-1 (left) and BM-2 (right) sonobuoys, with BM-1 hydrophone at lower left and BM-2 array at lower right. (U.S. Navy)

this buoy uses printed circuits and transistors, but it has no integrated circuits. BM-1 and -1A (1968) dimensions: 6 × 47.5 in, 33 lb. There is also a BM-2 (1969, 9 × 57 in, 97 lb).

Because BM-1 and BM-2 were associated with the Wet Eye radar (used on board May ASW aircraft), the buoy was not back-fitted into Hormone shipboard helicopters. These buoys are also associated with Bear F.

◆ Type 75

In 1988 the U.S. DoD released a photograph of a Soviet Type-75 sonobuoy that had electronics similar to those of the U.S. SSQ-41B, albeit in a much larger package. The conclusion seems to be that, since 1975, the Soviets have had LOFAR buoys. This conclusion would be consistent with sightings of Soviet listening devices, short cylinders covered with spot hydrophones, from about that date onward. LOFAR or LOFAR-like techniques, in distinct contrast to earlier passive techniques, operate on the basis of the detailed structure of the submarine's signature. They, therefore, entail an intelligence effort to obtain such signatures and then to match them against particular types of submarines. That effort would account for the bottom-laid devices, which are generally near NATO-submarine operating areas and bases. These devices are not themselves surveillance devices but rather are a means of collecting the information required to make the surveillance devices, such as LOFAR buoys, effective. The existence of such buoys also implies that the Soviets have the necessary signal processors, which in turn could be adapted to monitor towed passive arrays.

Type 75 entered service in the early 1980s. It is associated only with Bear-F aircraft.

In 1988 the U.S. DoD released these photographs of the Soviet Type 75 sonobuoy, which was described as similar to the U.S. SSQ-41B, i.e., to a LOFAR buoy. (*Soviet Military Power*, DoD)

UNITED KINGDOM

SONOBUOYS

◆ SSQ-904

This mini- (5 in × 12 in) Jezebel (LOFAR buoy) is made by Dowty. SSQ-904 operates at 10 Hz–6 kHz, at a depth of 60, 300,

or 450 ft, with a lifetime of 1, 4, or 8 hr. SSQ-904 can signal on 1 of 31 or 99 channels, operating with an AQA-5 or an AQS-901, -902, or -903 processor. This design resulted from MoD studies of the late 1970s, followed by field tests in 1979 and production in 1980; reportedly 12,000 buoys had been ordered through 1986.

In 1983 Ultra, which then manufactured SSQ-904, was reportedly working on a short 11-element vertical-line-array buoy for better shallow-water performance.

As of mid-1987, Dowty had manufactured a total of 550,000 sonobuoys for the RN, the RAF, and overseas customers, making the company the largest manufacturer in Europe. Customers that year included India and Sweden.

Dowty proposed SSQ-904 in 1978 as a reduced-size buoy for helicopters. The success of this buoy led in turn to the 1984 proposal for the G-size SSQ-954, which entered service in 1985. An enhanced F-size SSQ-904 Jezebel buoy entered service in 1988. It has 99 RF channels, selectable depth, and selectable lifetime (1, 4, or 8 hr).

Dowty claims that its passive buoys operate at significantly lower frequencies than do any others within NATO. That capability might be increasingly important as submarines become quieter.

◆ SSQ-905

This mini- (5 in × 12 in, 10 lb) Jezebel (LOFAR) buoy operates at 10 Hz–6 kHz; at a depth of 60, 300, or 450 ft; with a lifetime of 1, 4, or 8 hr; and on 31 or 99 channels. SSQ-905 is a calibrated version of SSQ-904.

◆ SSQ-906 and -907/SB112

These F-size (4.875 × 12 in) miniature Jezebel sonobuoys (weight 9.5 lb) have selectable lifetimes of 1, 4, or 6 hr; their hydrophones are carried at a preselected depth of 30 or 140 m (other combinations can be provided). The operating range is 4 Hz–6 kHz, buoy response being shaped to an inverse ambient sea noise curve to overcome average sea noise. Dowty describes this buoy as providing the lowest-frequency coverage in NATO. Buoys report by VHF radio on any of 99 channels (minimum output power 1 W). The buoy can be dropped from altitudes of 150–30,000 ft and at speeds of 60–300 kt.

Dowty sonobuoys, with 3 miniatures in the background and standard A-size buoys in the foreground. The buoy on the left is the SSQ-906 omnidirectional passive type; it is flanked by a BT buoy and by SSQ-954B. The 2 buoys in the foreground are a Dowty-made SSQ-47B and SSQ-963A CAMBS. (Dowty)

SSQ-906, introduced in 1988, is a -904 developed for reduced self-noise so that it can operate down to lower frequencies; it has significantly better LF performance than SSQ-906. The French navy currently purchases -906 from Dowty. As of 1989, Plessey and Dowty had contracts for a total of nearly 90,000 SSQ-906 buoys.

SSQ-907 is a calibrated version of SSQ-906.

Dowty is currently working on a new passive buoy to replace SSQ-904.

SB112 is a special moored version of SSQ-906 by Dowty.

◆ SSQ-937

SSQ-937 is an F-size XBT buoy. Lifetime is 5 min, and the buoy gives temperature down to 1000 ft (sink rate is 5 ft/sec). SSQ-937 operates on 1 of 3 preselected channels. Plessey's SSQ-937A measures down to 1500 ft in 6–12 min. It operates on 1 of 6 preselected channels.

◆ SSQ-947B

This British version of the U.S. SSQ-47B range-only buoy is omnidirectional. Frequency range is 13–19 kHz, and SSQ-947B reports on 12 channels.

About 1985 Plessey received a study contract for a new active buoy.

◆ SSQ-954/SB113

Plessey's G-size DIFAR buoy was announced in 1985. The hydrophone depth and operational lifetime of SSQ-954A can be remotely selected. Dowty describes the improved SSQ-954B as an Autonomous Function Selection (AFS) sonobuoy using a microprocessor to control the fully synthesized VHF transmitter, the operational lifetime (1, 4, or 6 hr), and the hydrophone depth (30, 140, or 300 m). Commands are transmitted via multifunction push buttons, and choices are indicated by light-emitting diodes (LEDs) when a "verify" button is pressed. Output power is 1 W, and shelf lifetime is 5 yr. The buoy can transmit on 1 of 99 channels, spaced 375 kHz apart. DIFAR compass accuracy is within 5 deg, and the buoy can also function in omnidirectional mode. The buoy can be dropped at speeds of 50–300 kt from altitudes of 150–30,000 ft.

Compared to SSQ-954 and -954A, -954B has a single button (rather than 3) to select frequency, depth, and lifetime. As of 1989, Plessey and Dowty shared contracts for more than 70,000 of these buoys.

SB113 is a special moored version of SSQ-954B by Dowty.

◆ SSQ-963

Dowty's Command A-size Active Multi-Beam Sonobuoy (CAMBS III) is currently in production for the RAF and Royal Navy. CAMBS uses 31 radio channels. Both the transmitter and the receiver are directional, and the transducer's depth can be varied on radio command. The buoy can operate either in directional passive or directional active modes; in the latter case it emits an omnidirectional pulse and receives with a separate directional array. Dowty describes SSQ-963A as representing an unspecified radically different but proven technical approach, compared to 2 earlier generations of CAMBS buoys. The buoy can be launched from altitudes of 200–8000 ft and at speeds of 60–300 kt. There are 3 selectable depths, and lifetime is 1 hr, with automatic or command scuttling. Shelf life is 5 yr. SSQ-963 costs about a third as much as CAMBS II but has better acoustic performance.

Plessey is currently working on a new active buoy.

In 1985, in connection with a proposal to equip Lynx helicopters with sonobuoys (to localize submarines detected by towed array), GEC Avionics claimed that a 3-CAMBS pattern would enable a helicopter to cover more than two-thirds of the area swept by a dipped sonar. The Lynx, however, could accommodate only 9 A-size buoys, and CAMBS could not be miniaturized because it depends on large batteries.

◆ SSQ-981

SSQ-981 is Barra: see the Australian SSQ-801.

◆ SSQ-991

Plessey's A-size air-launched sonar transponder (ALST) buoy was developed for British ASW helicopters, to serve as a reference point for their Type 195M dipping sonars. The buoy carries an octahedral radar reflector, optimized for X-band (cross section is 3–12 m², depending on elevation angle). Although the buoy is delivered preset to 195M frequency, it should also permit a shipboard operator to correlate radar and sonar pictures and, thus, to vector a torpedo-delivery helicopter more accurately. Such correlation becomes more important at greater sonar ranges. For example, in the early 1960s, when the U.S. Navy wanted to extend the range of its DASH delivery drone to maximum direct-path sonar range (about 20,000 yd), it had to develop a transponder buoy, Lorelei. The British frigate helicopter delivery system, using Lynx helicopters, is analogous (the main difference is that the pilot on board the helicopter greatly increases its reliability), and presumably ALST is partly a means of extending effective Lynx range (Lynx has no reacquisition sensor on board). The acoustic transponder floats 20 m (about 66 ft) below the surface, and its effective range is about 8000 yd. Operating modes include CW, shaped CW, doppler simulation (frequency-shifted pulses), and FM pulses. Buoy lifetime is 12 hr, including 3 hr of active operation.

Plessey offers a modified form of this buoy as a pure radar datum point, ALRT (air-launched radar target). ALST weighs 8.6 kg; ALRT weighs 7.0 kg. ALST can operate up to sea-state 3, in surface winds up to 15 kt.

AIRBORNE SIGNAL PROCESSORS

◆ AQS-901

GEC Avionics's signal processor for British Nimrod and Australian P-3 aircraft is adapted to Barra buoy processing. AQS-901 replaces the U.S. AQA-5. The full installation consists of 2 sets, each capable of processing 8 sonobuoys, connected by a data bus. The associated computer is GEC's 920 ATC with up to 256 kwords, capable of performing an FFT on 2048 points in 11.25 millisecc.

The associated receiver is tunable to 99 channels, and there is a command system to operate active buoys (it controls pulse width, pulse type, and PRF). The displays are CRTs and hard-copy chart recorders. The system can be set to alert an operator automatically when a target has exceeded a preset threshold.

AQS-901 was first delivered in March 1979. Production ended in the fall of 1986. Total production: RAF, 83; RAAF, 60.

◆ AQS-902 (LAPADS)/AQS-920 Series

Lightweight Acoustic Processing-and-Display System, in British Sea King helicopters, uses some AQS-901 technology but is only about 20% as large. LAPADS can also process dipping sonar data. AQS-902 entered service in 1980 on board Sea King helicopters, and in 1983 DIFAR processing capability was added. In 1985 GEC designed a new CRT to replace the paper recorder, to save another 20 kg and allow the processing capacity to be doubled.

As displayed in 1984, LAPADS was a passive analyzer for the 0–3.2-kHz band, with both LOFAR and A-scan displays. The main stated advantage was LAPADS's ability to combine wide-band (surveillance) with narrow-band (LOFAR, target classification/tracking). AQS-902 has 12 verniers (800, 400, 200, 100, and 25 Hz wide) that can be positioned anywhere in its displays, and it can display 12 LOFARS simultaneously. A harmonic cursor allows the operator to compare a line with its harmonic. Up to 1.5 hr of LOFAR history can be stored, for line enhancement.

Variants:

902A, described by GEC as essentially a digital equivalent to the U.S. AQA-5, is limited to hard-copy grams for pas-

sive omni buoys. Capacity is up to 4 buoys. This system replaced the U.S. AQA-5 in British service.

902B is 902A plus a CRT display, for the Fokker Maritime Enforcer. It has 2 units plus a central console for tactical integration.

902C is the version for the Indian navy's Sea King helicopters. It is capable of processing directional buoys (4 LOFAR and 1 BT or 4 DIFAR buoys); it has a CRT display. The total weight is 112 lb.

902D is the Royal Navy's version for Sea King HAS.2 and HAS.5. The Type 195 dipping sonar operates independently. This version is being updated to 902G-DS standard (see below).

902D-DS is 902D plus a processor for dipping sonars.

902F is capable of processing 4 LOFAR, 1 BT, and 4 range-only buoys; or 4 DIFAR and 2 DICASS; or 4 VLAD buoys. It is the version adopted for the Turbo-Tracker conversion.

902G was the version proposed for the U.S. SH-2G program, but it was defeated by UYS-503.

902G-DS is a new Royal Navy version (the contract was awarded to GEC in 1987) with a CRT and a sonar processor. One of the displays, the acoustic localization plot, allows the sonar operator to check the validity of the data before passing them to the observer's tactical plot. The tactical plot of the range and bearing information derived from the buoys provides current and predicted target information and track. In all, 112 processors are to be modernized.

The AQS-920 series, the export version, is typical of modern practice. A detailed description is available; the reader should assume that other current airborne processors are broadly comparable (e.g., in integration time).

The 2 current versions of AQS-920 are AQS-924 and -928; their maximum buoy-processing capabilities are

	AQS-924	AQS-928
LOFAR/DIFAR/VLAD (Omni)	4	8
DIFAR/VLAD (Cardioid)	4	4
Calibrated Buoys	1	1
DICASS	2	2
Range Only	4	4
BT	1	1

Passive processing modes are LOFAR/DIFAR/VLAD omnidirectional, DIFAR/VLAD pseudo-omnidirectional, DIFAR/VLAD single cardioid, DIFAR/VLAD triple cardioid, CODAR, DEMON (demodulated noise), BT, ambient-noise measurement (ANM), and signal-to-noise ratio (SNR). Active modes are DICASS (CW/FM), range-only (CW), and dipping sonar (CW/FM/BT/Depth). The processor can display passive buoy data either in LOFARgram form or in automatic line integration (ALI) form (i.e., integration can be either by eye or by machine). The advantage of using a LOFARgram is that the eye may detect an intermittently transmitted but fairly regular signal, whereas line integration may show little indication above the surrounding noise. Active formats are range/doppler/bearing, range/time history, bearing/time history, and range correlogram (using FM signals).

For detection, the system can perform simultaneous wide- and narrow-band analyses, cardioid detection gain, and automatic alerts. For classification, the system provides harmonic multipoint dividers, so the operator can compare the same line in several harmonic forms. For localization, the system can provide narrow-band frequency/bearing trackers, semiautomatic CPA/doppler fixing, and an acoustic localization plot (ALP).

The system has 4 or 8 channels to handle buoys in the 10–2400-Hz frequency range and can handle 10 narrow bandwidths or resolutions. The display covers a time history of up to 64 min, and integration time (for ALI) is selectable at 3.75, 7.5, 15, or 30 sec. The maximum number of analyses processed

is 8 BBAs (broad-band analyses: 688 cells) plus 24 VWs (vernier widths, i.e., narrow-bandwidths: 180 cells).

Total system weight, excluding the sonobuoy receiver itself, is 52.5 kg. That weight includes one or two 625-line CRTs and a hard-copy unit (for passive buoys only, to print out LOFARgrams).

AQS-902 is the standard Fokker Maritime Enforcer processor. Users of the Enforcer are Angola (1), the Netherlands (2, used by Fokker for system development), Nigeria (2), Peru (1), the Philippines (3), Spain (3), and Thailand (3). Of these countries, Angola has probably not been permitted to buy AQS-902, and Thailand has not installed a sonobuoy processor.

Users of this series of airborne signal processors are Greece (LAPADS in 14 HU-16Bs), Italy (update of Atlantic Mk 1 with AQS-902 and IGUANE radar), India (Sea Kings), Pakistan (projected Atlantic Mk 1 modernization with AQS-902), Sweden (6 AQS-924s ordered in 1984 for patrol boats, AQS-928 ordered for similar installation in 1990, plus probably 3 on aircraft), Taiwan (32 Turbo-Tracker conversions with AQS-902F), Turkey (projected Turbo-Tracker conversion of 18 S-2Es with AQS-902F), and the United Kingdom (Sea King HAS.6 helicopters). A projected Korean program for 36 Turbo-Trackers will almost certainly be canceled in favor of new P-3s.

◆ AQS-903

AQS-901's successor, made by GEC Avionics, employs VHSIC technology, for the EH-101 Merlin helicopter. AQS-903 can process Barra and CAMBS sonobuoys. This processor weighs about 160 kg, about one-third lighter than AQS-902, with up to 5 times the processing power. With 1 operator, AQS-903 can handle as many buoys (16) as the 3-operator AQS-901 and can provide each buoy with 8 times the processing power (e.g., to handle much more bandwidth).

The distributed processing architecture employs "pipelines," each of which handles a certain number of buoys. The manufacturer claims that 4 such lines give 8 times the power of an AQS-901 at a quarter of its weight.

GEC's AQS-930 series is presumably related to AQS-903 as the AQS-920 series is related to AQS-902. The announced versions are AQS-932, -934, and -938, the differences presumably being in the number of "pipelines." Announced maximum processing capabilities are

	AQS-932	AQS-934	AQS-938
LOFAR/DIFAR/VLAD (Omni)	16	32	64
DIFAR/VLAD (Cardioid)	8	16	32
Barra	2	4	8
DICASS	4	8	8
Calibrated Buoys	1	1	1
CAMBS	3	6	6
BT	1	1	1
Weight	66.5 kg	74.5 kg	82.5 kg
(including APU)	32.0 kg	40.0 kg	48.0 kg

Here APU is the acoustic processing unit; all of the other components (acoustic control unit, two 12-in 625-line acoustic display units, a common control unit, and a roller ball control/stiff stick control) are common to all versions.

Processing modes are as in AQS-924/928, except that the 930-series uses DIFAR/VLAD 4-cardioid rather than triple cardioid, and a Barra broad-band option is added.

Added detection aids (compared to AQS-924/928) are narrow/broad-band AGC (automatic gain control), broad-band power/bearing (DIFAR/Barra), and display enhancement. The additional classification aids are predictive (ratio) dividers and recorded data recall. Added localization/tracking aids are broad-band bearing trackers, automatic/manual CPA/Hyfix, and a coordinated tracker for multiple contacts. The LOFARgram display can show up to 60 min of history. No data are provided concerning maximum integration time.

Both the AQS-930 series and the AQS-920 series can process dipping sonar data.

UNITED STATES

SONOBUOYS

The total U.S. Navy sonobuoy purchase in FY89 was 376,000, including 15,000 SSQ-36 XBTs. Current U.S. policy is to use directional buoys (DIFAR, DICASS) only and not to purchase omnidirectional buoys. Although more expensive than the omnidirectional type, the directional units are not needed in the same quantities. The problem is that, in peacetime, maritime-patrol aircraft must often track submarines for protracted periods. In wartime (for which the systems were designed), tracking would continue only long enough to make an attack. Thus it was common for a patrol airplane to drop as many as 60 buoys while tracking a submarine during an 8-hr period. In recent

years, tracking has required such great expenditures that some have suggested that a period of prewar tension (requiring sustained tracking) would exhaust sonobuoy reserves. The low-cost sonobuoy was proposed in part as a solution to this problem since in theory it could be made and used in great quantities at affordable prices.

The table below (released early in 1990) shows U.S. annual sonobuoy procurement and consumption (in thousands), historical and planned, with consumption in parentheses. Unit cost is given below consumption.

The FY90 figures were later increased by Congress, which added \$45 million for procurement, increasing the total to \$160 million. Reportedly, the navy expends about \$130-\$150 million worth of sonobuoys per year.

◆ MCSS

The active moored buoy (moored CASS) is deployed over the side; the hydrophone is deployed at a depth of 20-700 ft. MCSS is rechargeable for continuous operation and is tunable to 1 of 3 channels.

◆ SSQ-23

Although no longer in U.S. service, SSQ-23 is produced in Japan by Oki as HQS-3D. It is an A-size (16 lb) passive omnidirectional buoy, covering the acoustic range between 400 Hz and 6 kHz, used for Julie explosive echo ranging. The Julie system became operational about 1957.

◆ SSQ-36 (XBT)

This expendable bathythermograph is designed to establish acoustic conditions in a sonobuoy field. SSQ-36 has a cable probe down to 1000 ft and is A-size (18 lb). Although the XBT is not a sonobuoy, it is essential to sonobuoy-field operations and, therefore, is listed here. Lifetime is 5 min, and SSQ-36 reports on 1 of 3 RF channels.

◆ SSQ-41

The standard U.S. A-size (14 lb) omnidirectional LOFAR buoy is a line hydrophone operating at 10 Hz up to 20 kHz at a depth of 60 or 300 ft, with a lifetime of 1, 3, or 8 hr. SSQ-41B (Jezebel wide-band) operates at up to 10 kHz (with improved dynamic range) at a depth of 60-1000 ft, reporting on 1 of 31 channels between 162.250 and 173.5 MHz or 99 channels between 136 and 173.5 MHz. Weight is 14 or 15 lb. SSQ-41B can be launched at up to 370 kt and at altitudes as high as 30,000 ft. SSQ-41A's maximum weight is 21 lb; -41B's, 29 lb.

In 1988 the U.S. DoD published a photograph of a Soviet Type 75 sonobuoy that was said to resemble SSQ-41B, albeit in a larger envelope.

SSQ-41 replaced SSQ-28, the first LOFAR buoy (1960), in 1965. SSQ-41 had sufficiently broad response to be usable in

Sonobuoy stowage on board a P-3C of VP-22, NAS Adak, November 1987. (Jürg Kürsener)

Julie and was described as a Julie-Jezebel buoy. SSQ-41 is the most widely used Western buoy.

◆ SSQ-47B

This active (range-only) A-size sonobuoy (29 lb) uses a hydrophone at a depth of 60 or 800 ft and has a life of 30 min. SSQ-47B is tunable to report on 1 of 12 channels, so that up to 6 buoys can be used simultaneously in a single field. SSQ-47B is a deep-operating version of the SSQ-15, incorporating solid-state electronics, controlled transducer beam, and VHF antenna patterns. Command is possible from 0–10 nm and from 500–10,000 ft, at up to sea-state 5. The operating mode is automatically keyed CW; because this buoy is not command-activated, its life is so short.

The last U.S. Navy production orders were in 1982; in 1988 this buoy was manufactured only for foreign military sales.

◆ SSQ-50

Command-Activated Sonobuoy System (CASS) is now superseded in U.S. service by SSQ-62 (DICASS). The signal is omnidirectional. Lifetime is 1 hr (half an hour for SSQ-50B), and the hydrophone depth is 60 or 1500 ft. There are 31 radio channels. Acoustic frequencies are 6.5, 7.5, 8.5, and 9.5 kHz.

◆ SSQ-53/SSQ-73 (DIFAR)

The directional LOFAR buoy (DIFAR) operates at a depth of 90 or 1000 ft, with a lifetime of 1 or 8 hr, at a frequency of 10 Hz–2.4 kHz. SSQ-53 is A-size, weighing 26 lb, and was standardized in 1969. SSQ-53B, the current version, weighs 22 lb (Sparton version), and its hydrophone operates at a depth of 100, 400, or 1000 ft; lifetime is 1, 3, or 8 hr, and reporting is on 1 of 99 RF channels. SSQ-53B reduces the LF mechanical noise found in SSQ-53A, and the operating parameters are chosen by push button (verified by light-emitting diodes on the buoy). The sonobuoy can be launched at up to 370 kt and from as high as 40,000 ft. The first SSQ-53Bs were delivered early in 1984.

In 1989 the unit price of an SSQ-53B was \$240, a figure Magnavox reached by using a robotic production line. After FY89, -53D will supersede -53B.

SSQ-53C is a full-function DIFAR buoy in Dwarf (G) size (16.5 in long but with an A-size diameter), fully equivalent to SSQ-53B (but launchable only from 30,000 ft or below). Weight is 11 lb.

SSQ-53D is a dwarf version with its frequency range extended

to lower frequencies. It also enjoys lower self-noise, largely by decoupling the hydrophone from the rest of the buoy assembly.

SSQ-73 was an experimental deep DIFAR buoy (A-size). It was described as the deep suspended DIFAR (DSD), and it was superseded by VLAD.

Sparton has developed a Dwarf DIFAR (A-size diameter but 12 in long; 10 lb). Operating depth is 90–1000 ft, and operating life is 1 or 4 hr; the buoy is tuned to 1 of 99 channels. No standard designation has been released.

◆ SSQ-57A

This low-cost passive A-size buoy (14 lb) operates at 60 or 400 ft; lifetime is 1, 3, or 8 hr. SSQ-57A operates on 1 of 31 channels. The hydrophone is Sparton-designed, the company claiming smooth response up to 20 kHz. The company claims that the buoy is effective at ranges of up to 10 nm and is launchable from 100–30,000 ft at 45–370 kt, into seas up to sea-state 5.

This buoy is used either for calibrating ambient sea noise (which is why smooth response is important), for monitoring exercises, or for collecting acoustic intelligence (where a smooth response can reproduce an unknown submarine signature, a narrower-band buoy might miss important parts of the spectrum). SSQ-57A is similar in mechanical design to SSQ-41. FY88 procurement was 11,947; FY89, 12,378. SSQ-57A has been sold at least to Australia.

As of mid-1989, an SSQ-57B was in the design stage; it was described as an SSQ-41 replacement with slightly greater bandwidth. Magnavox was to make 43,000 under the FY89 program.

◆ SSQ-58A (MIUW)

This special moored buoy for Mobile Inshore Undersea Warfare is an element of a movable surveillance system. MIUW consists of a 36-in diameter, 24-in deep, foam-filled fiberglass float, from which are suspended its mooring and its hydrophone assembly, and from which projects its antenna. MIUW is deployed over

Typical deployment sequence of an SSQ-53 sonobuoy. (Sparton)

SSQ-58A buoy for mobile inshore underwater warfare. (Sparton)

the side of a boat or small craft, typically in depths between 40 and 110 ft (an optional deep mooring kit allows for a depth of 600 ft). Minimum hydrophone depth is 20 ft. There may also be a deeper-mooring version, since earlier literature listed MIUW with a maximum hydrophone depth of 700 ft. The buoy can survive in tidal currents of up to 3 kt and in surface currents of up to 6 kt. Frequency range is 50 Hz–10 kHz, and the hydrophone is omnidirectional (with a flow shield). Operation is continuous because the buoy carries a 12-volt commercial rechargeable lead-acid battery; lifetime between recharging is 100 hr. The buoy reports on 1 of 31 VHF channels, and it carries a radar reflector atop its quarter-wave antenna. There is also a navigational warning light, which can be enabled or disabled as required. As of 1989, MIUW was in limited production by Sparton.

The SSQ-58 designation originally applied to a LOFAR buoy that could be anchored in up to 500 fathoms of water (3000 ft) and had a 30-day lifetime, to operate in currents up to 5 kt and in sea-state 5 (and which could survive 40-kt seas in sea-state 6).

◆ SSQ-62 (DICASS)

Directional command-activated active sonobuoy (DICASS) is used for localization of a submarine detected by passive buoys. On command, DICASS can determine a submarine's range, bearing, and speed (from doppler). SSQ-62 uses FM or CW pulses; their lengths and intervals can be chosen via 1 of 4 preset acoustic channels. Transmission is ODT, but reception is directional. DICASS operates at 60 or 1500 ft and weighs 39 lb. The feasibility contract was let to Sparton in 1968.

The current SSQ-62B weighs 34 lb and has a lifetime of 30 min. SSQ-62B adds a third depth: its transducer operates at 89, 396, or 1518 ft (as commanded), and -62B reports on 1 of 31 RF channels. The surface unit employs a seawater battery; the submerged pinger uses a lithium battery. SSQ-62B replaces the SSQ-48B Miniature Range-Only Buoy and is a follow-on to SSQ-50. Current procurement: FY88 was 12,229; FY89 was 17,464.

Raytheon, the developer, claimed that SSQ-62 was the first of its kind to be compass oriented, providing aircraft with true bearing on a target.

◆ SSQ-71

See submarine communications systems in the Surveillance and Control section.

◆ SSQ-75 (ERAPS)

Expendable RAP active buoy began development in 1961. ERAPS is command-activated, uses 2- or 5-sec pulses, and has a 3-hr life (power for 100 ping-seconds). SSQ-75 uses an LF pinger and a volumetric (circular array of vertical dipoles) receiving array, sufficiently directive to provide target bearing as well as range; target speed is estimated from doppler. Depth could be 60 down to 16,500 ft (typically 15,000 ft in the Atlantic, 6000 ft in the Mediterranean). Maximum range is about 15 nm.

Buoy dimensions are 10 × 91 in (325 lb); the buoy will be carried on a weapons rack rather than in a buoy chute. Presumably, 1 of the advantages of the new P-7A, with its enlarged weapons bay, is that it can carry a useful number of ERAPS buoys.

The preliminary design was reviewed in FY82, airdrop mechanical tests and over-the-side acoustics tests were conducted in FY83, 315 ERAPS buoys were bought for operational tests in FY84/85, and an airdrop succeeded in FY85. In 1986 Congress directed that the program be restructured for FY87, the goal being a unit cost of \$6000 for a production run of 10,000 buoys. Tests were scheduled for completion during FY88, with production to follow in FY89.

This program has been delayed. In November 1987 Magnavox and Sparton formed a joint venture, ERAPSCO, for ERAPS. They received a 53-month full-scale engineering-development contract in 1988. Overall subsystem integration was to be completed by July 1990. Technical and operational evaluation

should be conducted in 1992–93, and the navy will probably procure about 2000 ERAPS buoys per year beginning in 1993.

In an FY83 experiment, an ERAPS receiving array was used as a baseline high-gain array, as a first step in developing an advanced localization buoy.

◆ SSQ-77 (VLAD)

VLAD, a vertical-line-array DIFAR buoy (A-size, 29 lb), uses 9 omnidirectional hydrophones and 2 geophones in place of the single DIFAR hydrophone of its predecessor, SSQ-53B. A conventional DIFAR hydrophone mounted at the array's phase center provides bearing data, and the other hydrophones are used to detect BB signals and to discriminate against shipping noise from the surface. The entire array is carried in a faired cable, the fairing reducing cable noise ("strum"); and the array is held vertical by a terminal weight and is stabilized in direction by a 15-ft drogue, a water-filled plastic bag acting as a sea anchor. Depth is 1000 ft; lifetime is 1 or 8 hr; and frequency range is 10 Hz–2.4 kHz. Each buoy can be preset to 1 of 99 radio channels.

The signal format is identical to that of the SSQ-53B DIFAR, so the buoy is compatible with existing AQA-7 processors, found on board P-3s. All beam-forming is performed within the buoy. Apparently the vertical orientation of the beam is preset; a sketch provided by Sparton shows a buoy adjusted to detect BB signals, rejecting surface noise and horizontal signals.

During the mid-1970s VLAD was chosen for production instead of the alternative DSD (SSQ-73) buoy. Both buoys reflect the ASW concepts of the late 1960s and were attempts to overcome the improved silencing then expected of the new generation of Soviet submarines (Charlie, Victor, Yankee) and their successors. Sippican acquired rights to manufacture SSQ-77A, a modified version, from Hazeltine in March 1984. Modifications made for production included redesign of the surface float. Pilot production began in May 1984, full-scale production following in 1986. Sippican's description involves 11 omnidirectional hydrophones (and no geophones) and alternative lifetimes of 1, 4, or 8 hr, but it is not clear whether these are changes specific to SSQ-77A.

VLAD buoys were initially manufactured in alternative BB and horizontal-beam versions, the latter intended to avoid shipping noise in the surface layer. VLAD was initially unpopular because users were unfamiliar with BB operation. Current VLADs can be set to different beam angles before they are launched.

In FY76, 2000 SSQ-77 service-test models were bought; operational evaluation was successful, and the buoy was approved

Operating geometry of the SSQ-77A VLAD buoy. (Sparton)

for service use late in FY78. Production began in FY80 with 1000 units, followed by 7000 in FY81 and by 23,000 in FY82. Recent procurement: FY87, 98,812; FY88 request, 51,663; FY89 request, 34,874.

A long-life commandable version of VLAD was tested in FY81 and FY82.

◆ SSQ-79 (SVLA)

This steerable vertical-line array (SVLA), in A-size, operates at 1000 ft, for a 4- or 8-hr lifetime. This buoy is also called the Passive Advanced Directional Sonobuoy (PADS). Hazeltine received the advanced development contract in FY76 and began work in FY77. SSQ-79 uses a third-generation sensor, VLADFA (VLAD Frequency Analysis), with a digital uplink. Developmental test and evaluation (Phase II) was completed in FY83. In FY86 (ca. March 1986) the estimated requirement was 480 prototypes and 2000 initial-production buoys for completion of tests through FY87.

This buoy was developed under a Passive Advanced Detection System program begun in FY70.

◆ SSQ-83

SSQ-83 is a SAR (sea-air-rescue) up-link buoy (ULC).

◆ SSQ-86

SSQ-86 provides down-link communications, DLC. See submarine communications systems in the Surveillance and Control section.

◆ SSQ-90

An active multiple ping (AMP) B-size (103-lb) buoy, SSQ-90 is currently in limited production.

◆ SSQ-101

A buoy with a horizontal-line array (HLA), SSQ-101 was initially dropped in favor of vertical-line arrays. However, because it can form horizontal beams, it can block out noise, and in theory it can achieve long search ranges. HLA is being developed both as a long-range passive buoy (for battle-group screening and for large search areas) and as the receiver of the ADAR system (see below), using LF active sources. It is now being developed to meet the new quiet submarine threat. HLA should enter full production in 1995. An Operational Requirement was issued in November 1985, and in mid-1986 the navy sought bids for full-scale engineering development, including production of 400 buoys. Previous development efforts included packaging and acoustic tests in FY81, over-the-side tests in FY82, and over-the-side performance tests in FY83.

◆ SSQ-102 (TSS)

Hazeltine/Sippican and Boeing/Magnavox/TRW are competing to develop this tactical surveillance sonobuoy (TSS) for completion by February 1994. SSQ-102 is to be a long-duration (in-water life at least 5 days) A-size buoy for wide-area surveillance. A processor in the buoy selects and records signals of interest, which are played back at high speed upon interrogation by an airplane. Each individual buoy will not cover a very large area, but the command playback permits 1 airplane to monitor a very large field since it need not be simultaneously within radio range of each buoy. From a functional point of view, a field of TSS buoys would appear to be equivalent to the defunct RDSS.

A projected enhanced version (ETSS) should increase system gain by using a better array or by incorporating an in-buoy trigger modification.

Tentative Operational Requirements for TSS and ETSS were issued in June 1985. System definition was completed in FY86, and both competitors were awarded FSED contracts, each calling for 625 buoys for technical and operational evaluation in 1989. Overall system design was completed in FY88, and ETSS engineering development began in FY90. One of the 2 TSS alternatives is to be selected in 1992.

◆ SSQ-103

This low-cost sonobuoy (LCS) may replace earlier LOFAR types. In Sippican's version, SSQ-103 is one-sixth of A-size and is intended for deployment in dense fields. Unlike a LOFAR buoy, which measures a detailed acoustic spectrum for analysis on board a monitoring airplane, an LCS measures gross (broad-band) noise nearby, integrating (in effect) over much of the spectrum. That scheme cannot match the range sometimes achievable with LOFAR, but LCS should be able to detect the noise of water flowing over the hull of a nearby submarine, a noise that is essentially impossible to eliminate. Because detection range is likely to be very limited, a detection by an LCS should indicate that a submarine is quite close, and that indication in turn may be a sufficient attack criterion. Alternatively, a detection may lead to a second phase during which more sophisticated buoys can be dropped. Ironically, the LCS brings sonobuoy operation back to the early 1950s, when passive buoys were all broad-band. At that time, simple silencing measures (such as intermittent snorkeling) seemed likely to overcome such buoys, and active alternatives (Julie) were proposed. LOFAR made passive buoys viable, and only now, more than 3 decades later, does the potential of passive operations seem about to be exhausted.

LCS does differ from the primitive buoys of the 1950s, which were not nearly sensitive enough to detect flow noise at useful ranges (and which relied on the noise of snorkeling). LCS deploys a passive multi-element array down to a depth of 300 ft and continuously compares the received energy level in the water to a measured figure, thus reducing the effect of background noise. Each buoy is 4.5 in × 5.5 in long, and 6 are packaged in each A-size launcher. The cost limit is one-tenth the cost of a conventional passive buoy, and the projected production rate (from the late 1980s) is 500,000 units per year.

Low-cost sonobuoys (SSQ-103), individual and stacked in an A-size casing. Not shown is the array deployed 300 ft below the buoy. (Sippican)

Both Sippican and Sparton have developed alternative versions of SSQ-103. Sippican's is coffee-cup shaped; Sparton's is cylindrical. Each is essentially A/6-sized, and each is designed for laying in a very dense field. Sippican's can be tuned to any 1 of 330 channels. Sparton's can be tuned to 1 of 66 channels and, presumably, is intended to come in any 1 of 5 versions (a smaller number of tunable channels would mean a simpler and, therefore, less expensive frequency synthesizer in the buoy).

Quite aside from the need for new tactics to counter very quiet submarines, the LCS project is sometimes justified on the grounds that existing buoys cannot be bought in sufficient numbers for protracted operations. One fear is that submarine surveillance during a lengthy crisis, which might or might not lead to war, would exhaust stocks of the sophisticated buoys, leaving nothing for the war emergency. In theory, LCS might be a way of doing surveillance (as opposed to tracking up through an attack) at a lower cost, the better buoys being reserved for wartime. In this view, LCS cannot in itself provide sufficient localization for attack. In wartime, then, the more sophisticated buoys might be used for localization after area detection by LCS.

These projects seem to have been outgrowths of an Advanced Passive Sensors project for wide-area buoy search and advanced means of localization. LCS was intended as a follow-up to VLAD, using either a horizontal-line array (HLA) or STRAP (Sonobuoy Thinned Random Array Processing). A low-cost sonobuoy field would be a particularly simple form of STRAP, involving simpler, rather than more complex, processing. The problem in STRAP is that buoys cannot be laid in a precise pattern amenable to conventional acoustic processing. Therefore, the beam-former must adapt to the buoy's position, and that position must be precisely known. The technique in STRAP was to provide 4 of, say, 20 buoys with low-power emitters that could be picked up both by the airplane and by the other buoys. Each buoy would, then, transmit a mixture of acoustic and positional data, and the airplane could locate each one. Given these data, a powerful computer (UY-1) could develop appropriate beams. Lockheed conducted the first feasibility demonstrations, and sea trials followed in 1986.

STRAP was initially a broad-band buoy field evaluated first with SSQ-53 buoys. The effort then shifted to advanced manufacturing technology for the LCS needed to make STRAP practicable. The low-cost effort began in earnest in FY84 but was shifted to other projects in FY85.

It appears that development initially emphasized better signal processing and greater array gain. However, it would appear that work was redirected about 1983 (when ASW policy was reviewed), the expensive high-gain buoys being abandoned in favor of a relatively dense field of short-range buoys. Presumably, the current LCS program represents a further retreat from the ideal, of increased range through signal processing, that was represented by a DIFAR (SSQ-53) buoy: i.e., a further acknowledgment of the effect of submarine silencing.

The LCS program was planned in 3 stages: LCS, enhanced LCS (ELCS), and improved LCS (ILCS). LCS passed its Milestone I late in FY83 (i.e., in mid-1983), and an Operational Requirement for this buoy was issued in March 1985. The OR for ILCS was issued in May 1986. LCS was killed in favor of ELCS, and the FY89 budget included ELCS system studies as well as the appropriate modifications to the scanner of the ARR-78 sonobuoy receiver. However, by January 1989 the entire LCS program had been canceled, reportedly because sufficiently capable buoys could not be produced at a low enough cost.

The people that advocated LCS have not disappeared, and it seems certain that the program will reappear under a new name. As of mid-1989, the Naval Air Development Center was conducting an ELCS/ILCS (Enhanced/Improved Low Cost Sonobuoy) program for a "microbuoy" with on-board processor and auto-detection algorithm. Four teams completed parallel studies: Magnavox/Boeing, Sparton/Lockheed, Hermes/Lockheed, and Sippican/IBM.

◆ Advanced Buoys

Several advanced buoys are under development:

AAA Air Active Adjunct This device is a modernized Julie, in which a sound source is dropped in a field of passive buoys. During FY88 development options were examined for an Advanced Active Sonobuoy/Air Active Adjunct (AAS/AAA). The Tentative Operational Requirement for this buoy was released in April 1987.

AAS Advanced Active Sonobuoy A replacement for DICASS (SSQ-62). The Tentative Operational Requirement for this buoy was released in May 1986, and an RFP was issued in 1990.

ADAR Air Deployable Active Receiver There is also an HLA active receiver. The latter uses an HLA buoy as a multistatic receiver of shipboard and deployed acoustic sources, for detection and localization. This system should be ready for evaluation about FY92 and should be introduced in service by 2000. Initial over-the-side demonstration was conducted in FY88. Array alternatives were studied during FY89. The ADAR Operational Requirement was issued in November 1986.

AE Active Enhancement Program demonstration was scheduled for FY89. This program is also called DE, Doppler Enhancement. The program's improved low-doppler detection technique is ultimately to be incorporated into SSQ-62 or AAS buoys as an engineering change (ECP). Flight tests were completed in FY88.

AIS Acoustic Intercept Sonobuoy System integration began development in FY88. The tentative operational requirement for this buoy was released in August 1985. As of early 1989, 2 full-scale engineering development contracts were planned for FY90, with hardware development tests to follow in FY91.

ETSS Enhanced Tactical Surveillance Sonobuoy Trade-off studies were conducted during FY88. The Operational Requirement for this buoy was released in February 1986.

ITSS Improved Tactical Surveillance Sonobuoy The Operational Requirement (OR) for this buoy was released in February 1986.

TAS Tactical Arctic Sonobuoy A conventional sonobuoy is encased in a bomb-shaped chemical ice penetrator, which reacts with the ice, eating it away. Eventually the buoy falls into the vertical position and sinks through the hole made by the chemical penetrator, guided by fins in the penetrator's tail. The usual inflatable retarder keeps the buoy afloat in the water crater left by the penetrator. The U.S. program employs a solid lithium compound penetrator; the U.S. Navy signed a prototype contract with Sparton in mid-1987. A parallel Canadian program, using a nonlithium penetrator, began officially on 1 January 1988. The penetrator-encased buoy was first displayed at the 1989 U.S. Navy League show.

The Tentative Operational Requirement for the TAS was issued in July 1985.

◆ SDC Buoys

In 1984 the Space Development Corporation announced a new small-diameter (54-mm) LOFAR buoy equivalent to SSQ-41B; see the comments at the beginning of the entries on sonobuoys for SDC's claimed advantages. The buoy was conceived about 1972, to be fired by destroyers using Loki rockets (to ranges of about 60 nm); but although 1973 tests were successful, no orders followed. However, the small-diameter buoy became more attractive as smaller and smaller aircraft were proposed for maritime patrol. Early in 1984 Beech Aircraft took a sonobuoy on tour with the patrol/ASW version of its B200 Super King Air.

AIRBORNE SIGNAL PROCESSORS

◆ AQA-3/4

These LOFAR (Jezebel) signal processors for, respectively, S-2D and -2E Tracker aircraft are no longer in U.S. service but are

used in several Allied navies. Earlier versions of the S-2 lacked any Jezebel capability. They had, at best, an AQA-1 sonobuoy indicator. S-2E introduced a coordinated tactical navigation system to solve tactical problems, combining memory, display, and automatic computation.

AQA-3 and -4 were also carried by P-3A Orions.

These processors used paper (hard-copy) readouts (four 3-in-wide grams, for 4 buoys) and could also conduct CODAR analysis: the time of arrival of the same sound at 2 buoys could be used to give a line of bearing, so 2 pairs of buoys could give a cross fix. These were the first airborne LOFAR (Jezebel) acoustic processors.

LOFAR spectra were obtained by time compression. The sonobuoy signal had to be subjected to a series of matched narrow-band filters, the output of each filter appearing as a darker or lighter spot on the LOFARgram. It was impossible to apply the filters in sequence as the sonobuoy signal was received: each filter imposed a finite analysis time, and it would have been impossible to follow changing signals. The solution was time compression. The incoming signal was tape-recorded and transferred to a secondary analog memory that could be scanned very rapidly. In AQA-3, the secondary memory was a round magnetic tape about 5 in in diameter, which rotated slowly past an erase head and then past a recording head on its outer side. Pickup heads for analysis rotated rapidly on the inside; Bell claimed that this system was the earliest example of having recording on 1 side of a medium and pickup on the other side.

The compression ratio is the ratio of recording speed to pickup speed. Effective analyzer bandwidth is the full bandwidth of the fixed-frequency filter divided by this ratio. The faster the pickup rotational speed (which is fixed by strength of material), the narrower the bandwidth per filter and thus the greater the signal-processing efficiency of the system as a whole. The fixed-filter bandwidth cannot be shrunk.

The next step, then, was to go from a mechanical to a solid-state system, Deltic (Delay-Line Time Compressor). Deltic was incorporated in AQA-5. It was proposed at the Scripps Institution of Oceanography and initially implemented by Bell Labs, the basic patents being filed in 1956. A Deltic contains a digital memory and a delay line. Incoming acoustic data are digitized and recirculated. On each pass back through the analyzer, the oldest digit is dropped and another added. The product of clock rate and delay-line length is the multiplication factor. Greater multiplication factors could be applied both to multibuoy operation and also to better resolution in the analysis of each buoy. AQA-5 introduced Deltic. Compared to AQA-3 and -4, AQA-5 enjoyed an increased compression factor of about 17.

The LOFARgram paper printing mechanism corresponds to these electronic techniques. A single fine stylus sweeps across a paper, marking frequencies detected in the signal under analysis. Its sweep rate across the paper corresponds to the rate at which the signal is analyzed. The paper itself moves to indicate changes over time. The darkness of the marks corresponds to the strength of the frequency components in the signal, and clearly there is a tacit assumption that all or most of the signal remains steady over the time it takes the stylus to move across. The more resolution the system requires, the further the stylus must move in a given time (to provide enough indication per channel). Targets are detected by visual integration.

In contrast, a CRT display created by a digital analysis technique (FFT) will create the entire LOFARgram essentially instantaneously, all frequency components being developed at the same time rather than in sequence.

Deltic was still fundamentally an analog device, in that the time-compressed signal still went through a series of narrow-band filters. The next step was a fully digital device, a digital analyzer using FFT techniques. FFT was introduced in the OL-82 of the S-3A and probably also in the AQA-7 of the P-3C.

AQA-3 and -4 could handle a maximum of 4 buoys (4 LOFAR or 2 CODAR in AQA-3, 4 LOFAR or 2 LOFAR and 2 CODAR in -3A and -4). AQA-4 was similar to -3 except that it used a

single internal band to cover both broad-band and narrow-band signals.

AQA-4 was made by Western Electric.

Users are as follows:

In the P-3A: Spain (6 delivered, but 4 replaced by 5 P-3Bs bought in 1987). All 73 surviving U.S. P-3As and P-3Bs in Reserve service are being deactivated. The Spanish P-3As and -3Bs are being modernized to P-3C standard, with APS-134 radar and, presumably, AQA-7 processors, by Boeing. See also IPADS, below.

In the S-2E: Argentina (6), Italy (8 S-2Fs), Korea (36), Peru (9), Turkey (18 or more, subject to Turbo-Tracker modernization), and Venezuela (8); possibly also Brazil (8). The Argentine aircraft have been fitted with tactical computers, but apparently not with new sonobuoy processors, since 1982. The Turkish aircraft listed above were refurbished in 1985 and, thus, may well have AQA-7 processors like S-2Gs. Thailand still operates S-2Fs but is retiring them (rather than modernizing them) because of severe structural problems.

Both S-2Es and S-2Gs (AQA-7) incorporate ASW data links (2.2-GHz AKT-19), transmitting their sonobuoy data down to the operating ship for analysis. Presumably, the Argentine and Brazilian carriers have this capability.

◆ AQA-5

The signal processor for P-3B aircraft was later installed in British Nimrod, French Atlantic, and Japanese PS-1 and P-2J aircraft. AQA-5 was a development of AQA-3/4. AQA-5 had an improved Deltic (delay-line time compressor) processor and somewhat greater sensitivity and used surface-wave processing. A P-3B carried 2 AQA-5s. Compared to AQA-3/4, AQA-5 achieved improved classification by using a narrower effective bandwidth, a wider display, and better frequency resolution. AQA-5s were also used ashore, in ASW analysis centers (ASCACs) and on board aircraft carriers, to analyze sonobuoy data collected by ASW aircraft.

AQA-5 could handle up to 8 buoys: 8 LOFAR, or 6 LOFAR and 1 CODAR, or 4 LOFAR and 2 CODAR, or 2 LOFAR and 3 CODAR, or 4 CODAR.

An improved AQA-5, WAP II (Wide-band Acoustic Processor II), was used on board some frigates to process SQR-15 towed-array data. WAP III is used by IUWGs (Inshore Underwater Warfare Groups) in TSQ-108 vans.

These processors were built by Western Electric and Emerson. In British service they were replaced by AQS-901; in French, by SADANG (TSM 8210). Emerson Electric delivered its first AQA-5 in 1964 and produced a total of 650. A modified version was delivered to Australia, Britain, and Germany.

Deltic Jezebel was fitted to the 111th and later P-3As. It was associated with the ASA-50 ground-speed and tactical-bearing computer. The (V)2 version was used in the P-3B. Both were replaced by AQA-7.

AQA-6 was an abortive Magnavox digital sonobuoy processor containing 8 line integrators and 8 time compressors; it was intended to replace all existing airborne acoustic systems (1965), processing SSQ-28 (LOFAR) and -48 buoys.

Users are as follows:

In the Atlantic MK 1: France (30 in 1989), Germany (14), Italy (18, modernized with AQS-902 in 1988-90), Pakistan (4). The Dutch Atlantics were all discarded.

In the P-3B: Portugal (6 ex-Australian, designated P-3P), Spain (5 ex-Norwegian; see P-3A under AQA-3/4). The U.S. Naval Reserve P-3Bs are all being retired. The RNZAF P-3Bs have all been modernized with new acoustic systems as P-3Ks.

In the P-2J: Japan (28). The PS-1s have all been discarded.

◆ AQA-7(V)

AQA-7 was the basis of the P-3C, which carried 2 of these processors. S-2G Trackers (which are still operated by Uruguay as shore-based patrol aircraft) carry 1.

AQA-7 introduced DIFAR processing (using SSQ-53 buoys). Compared to AQA-5, -7 is more sensitive and has expanded frequency coverage. AQA-7 incorporates ALI (automatic line integration), which should permit automatic detection of a strong and consistent line. Signals are multiplexed in the sonobuoy with compass information. Within the AQA-7, they are demultiplexed and routed to a frequency translator compressor (FTC), where the frequency band of interest is translated to a processing band, sampled, and time-compressed independently in 8 channels. FTC outputs are spectrum-analyzed to provide target bearing (for a DIFAR or DICASS buoy) and to supply both paper (LOFARgram) and CRT displays.

(V)1, (V)2, and (V)3 use 2 frequency-multiplier-storer units instead of the FTC of the original AQA-7. (V)4 introduced the FTC. (V)5 uses a frequency multiplexer-storer. Versions differ in the FFT analyzer they use (see below).

With 8 LOFAR channels, AQA-7 can simultaneously process up to 8 LOFAR buoys, or 2 CASS active buoys, or 1 DICASS active buoy.

AQA-7 was first delivered in 1969. Five generations appeared between then and 1989, major improvements being single and then triple vernier, provision for DICASS, and provision for passive tracking. Broad-band algorithms were tested in AQA-7(V)13/14/15 between 3 January 1983 and 16 July 1985. All of these systems are manufactured by Magnavox.

Versions:

(V)1 analyzer MX-8440

(V)2 analyzer MX-8440

(V)3 analyzer MX-8440

(V)4 analyzer TS-3542. This version introduced single vernier analysis (1975). TS-3542/AQA-7(V) processes time-compressed signals by conducting a narrow-band search for frequency lines of interest; the signal's amplitude at each frequency increment is supplied to output as a digital word. Two complete DIFAR analyses are conducted in less than 1.25 sec with decreased time required for range signals. Its output consists of 16 time-compressed signals, 2 real-time signals, plus clocks and control lines from other parts of the AQA-7(V) system. Output information is stored in shift registers and supplied as required.

(V)5 analyzer TS-3542

(V)6 triple vernier added to (V)4, at the suggestion of the Operational Test and Evaluation Force (January 1979). Three portions of the spectrum are examined simultaneously. This and later versions use analyzer TS-3807. TS-3807/AQA-7(V) receives time-compressed LF signals from a frequency translator compressor, performs a narrow-band search for discrete frequency lines, converts the signal's amplitude at each frequency increment to a digital word, and stores the analyzed data in shift registers for output. Two complete DIFAR analyses are conducted in less than 1.25 sec with decreased time required for range signals. Input to the spectrum analyzer-quantizer consists of 72 time-compressed signals, 2 real-time signals, plus clocks and control lines from other parts of the AQA-7(V) system. Output information is stored in shift registers and supplied as required. The modified unit receives 72 time-compressed signals, whereas the previous spectrum received only 16 time-compressed signals. Additional modifications to input gating and to timing have been incorporated.

(V)7 triple vernier added to (V)4

(V)8/9 added DICASS capability (1980). These versions use frequency translator-compressor CV-3610.

A(V)10/11/12 are modified AQA-7A(V)8 and 9 with passive

tracking (PTA) added (1984). Bearing frequency control is deleted and a new bearing computer (CP-1532) and signal data recorder (RO-547) added. Enhancement 1 (TAC-NAVMOD) to AQA-7A(V)10/11/12 improves the man-machine interface (using an interactive control panel), provides Passive Tracking Algorithm (PTA—see LAMPS) capability (using an embedded processor), and improves communication between the processor and the airplane's CP-901 computer. Each ICP contains 2 control display terminals (CDT), each with over 100 programmable switch locations and a plasma display panel. The enhanced display modification proposed for naval reserve aircraft (IPADS) provides a 15-in diagonal CRT. Eight real-time LOFARgrams can be displayed simultaneously.

A(V)13/14/15 are modified A(V)10/11/12 with broad-band processing, using 4 channels of cross- or auto-correlation processing band with 3 operator-selectable input bandwidths. FFT techniques are used to perform the correlation processing and also to remove tonals. The latter is necessary to eliminate the interfering banding effects on the correlogram caused by narrow-band signals, and it solves a problem present in earlier broad-band processors. Affected processors can be reprogrammed on board, so little new hardware is needed. The earlier narrow-band and PTA features remain. New features are a demultiplexer (TD-1400), a new frequency translator-compressor (CV-3921), a new signal-data recorder (RO-574), and a new bearing computer (CP-1683 in (V)15). In (V)13 and 14, CP-1532A/AQA-7(V) performs automatic line integration, computes bearings and intensities for displays, and computes statistical parameters for automatic thresholding and data correction and tracking. It cross correlates and autocorrelates the broad-band signal as a function of the controls from the signal-data-recorder plasma panels. CP-1683 (for (V)13, 14, and 15) is functionally but not electrically similar to CP-1532.

B(V)18/19 IPADS processors for modernized P-3B aircraft. IPADS doubles the number of LOFAR channels provided by (V)11/12 (32 rather than 16), with 3 verniers per channel (all DIFAR and LOFAR rather than LOFAR only). As in (V)11/12, IPADS has 2 embedded PTA processors (8 channels). It doubles the number of doppler bearing tracker channels (16 vice 8) and provides 32-channel frequency alert (none in (V)11/12, 32 of post-processing in Update III CHEX). As in Update III CHEX (but not (V)11/12), there is a trackball. There are 99 sonobuoy channels (compared to 31 in the earlier (V)11/12).

◆ OL-82/OL-5004

OL-82 is Sanders's FFT sonobuoy processor for S-3A aircraft. OL-82 differs from its predecessors in lacking any paper print-out, and frequencies are presented logarithmically rather than linearly.

OL-5004 is a modified OL-82 for Canadian Aurora aircraft. It adds vernier displays and can measure ambient sea noise.

Both OL-82 and OL-5004 represent the beginning of a new generation of narrow-band systems, using FFTs to determine the spectral content of an acoustic signal. Incoming signals are converted into series of points (signal intensity at closely spaced time intervals) in digital form, and the spectrum is read off in digital form for further representation or analysis. FFT is now the standard means of spectral analysis in passive sonar applications, including those on board ships and on board submarines. Spectral analysis should be particularly well adapted to data-based systems, in which data pass from 1 console to another in digital form.

◆ UYS-1

IBM's Advanced Signal Processor (ASP), the first and current standard U.S. Navy acoustic-signal processor, is intended to re-

place a variety of special-purpose devices. Therefore, like many other current systems, it emphasizes programmability and can be upgraded by changes in software rather than by rewiring.

Production began in 1981, the 250th unit being delivered in October 1984. The initial requirement, as stated in 1981, was for 500 units.

UY-1 is a very high speed linear-flow computer, currently used in aircraft (P-3C UPDATE III, S-3B, SH-60B), submarines (BQQ-5C, BQQ-9, SUBACS), and surface ships (SQS-53B/C, SQR-19, UQQ-2 SURTASS); this computer is also used by the air force and army. The current version has a program memory of 128k 32-bit words, expandable to 256k with an engineering change. Bulk storage is up to 1024k 32-bit words, organized in 64-bit double words with 8 error-correction code bits.

Processing rate is 10–20 MFLOPS, with a total input/output rate of 1.25 Mwds/sec. Demonstrated MTTR is 12 min; predicted MTBF is 775–1100 hr, depending on configuration.

I/O is organized in up to 8 programmable channel pairs (combination of NTDS and Proteus).

In its aircraft form, UY-1 is 57.32 × 23.44 × 11.19 in, weighs 240 lb, and requires 1530 W of power.

Three ASP are packaged together as TRIASP, for the BQQ-5C Expanded DIFAR.

The UY-1 was designed for upgrading, given the very rapid evolution of computer technology. For example, as of 1984 ASP memory technology was already in its fourth generation, having evolved from 4k (bits per chip) to 64k. Improvements between the start of production, in 1981, and 1984 included doubling the central processor's control memory (2k to 4k 32-bit words), doubling the arithmetic processor's storage (2k to 4k 64-bit words), doubling the arithmetic processor's working storage (2k to 4k 32-bit words), doubling the program's storage (128k to 256k 32-bit words), and improving programmability using distributed program architecture microcode. Many of these improvements resulted from the replacement of 1k static memory by 4k read/write memory, cutting the net number of modules.

In November 1983 IBM completed its first VHSIC chip, capable of 100 MFLOPS, 10 times more than any previous reported chip, with 37,000 circuits on 64 mm² of silicon. Applied to an acoustic brassboard (VHSIC acoustic brassboard, May 1984), this type of chip permitted DIFAR signal multiplexing for twice as many sonobuoys as are currently available. A brassboard is not, of course, a working airborne computer, but this type of performance must have been important for the massive dwarf sonobuoy fields envisaged under the LCS program (see SSQ-103 above).

ASP software is currently being upgraded to match a simplified and improved programming method (Signal Processing Graph Notation, SPGN) developed for the more powerful UY-2. SPGN was demonstrated in a program called ECOS (EMSP common operating system). The ASP Common Operational Support System (ACOS) is a programming methodology by which acoustic engineers can implement signal processing graphs into ASP (UY-1) code without extensive computer training. ACOS Phase I SPGN applications development tools were implemented in FY88.

◆ UY-2

The enhanced modular signal processor was developed by Bell Labs (AT&T). UY-2 is intended for use by air, surface, submarine, and shore platforms, in acoustics, radar, EW, image processing, and communications. However, because UY-2 was conceived as an ASW signal processor, it is included here. The design concept called for a family of processors, with varying volumes and burst multiplication rates:

EMSP A 35 in³, 400 MFLOPS
 EMSP B 30 in³, 200 MFLOPS
 EMSP C 25 in³, 150 MFLOPS
 EMSP D 15 in³, 100 MFLOPS
 EMSP E 5 in³, 25 MFLOPS

High net speed is achieved by parallel processing (which AT&T called "multithread control architecture"). The EMSP is designed around 6 functional elements (FE), each consisting of a group of standard electronic modules (SEMs): a scheduler; a global memory (intelligent memory providing storage and memory management, in 2-, 4-, 6-, or 8-Mword modules); a data-transfer network; a command program processor; an arithmetic processor; and an I/O processor. Words are 16 bits long.

Predicted MTBF is 1250 hr for the largest configuration or 4000 for the smallest; predicted MTTR is 0.25 hr. The computer design can exploit future VHSIC or VLSI technology.

Planned UY-2 applications include the BSY-2 submarine CDS (6 UY-2 per submarine), the P-3C/P-7, and SQQ-89. NAVSEA claimed that in the P-3C, 1 UY-2 was equivalent to 14 UY-1s in the same size box. A UY-1 can handle 5 DIFAR buoys; a UY-2, at least 64.

EMSP is 1 of the first DoD VHSIC insertion programs (AT&T 1986–87). VHSIC was used for a new arithmetic processor with 46% more throughput than its predecessor and has been in units produced since 1988 for the BSY-2. Formal approval for production was granted in August 1989.

During 1989 there were some attempts to kill EMSP (UY-2) on the grounds that commercial processors could outperform it. EMSP had, after all, been conceived a decade earlier. Although UY-2 has 6 times the processing power of UY-1, some potential user programs bought UY-1 instead for fear that UY-2 would be canceled. Exponents of EMSP could point to the virtue of standardization, and also to the machine's capacity for later improvement. There was also some question as to whether most UY-2s bought would be built out of the SEM-B cards initially planned, or out of more capacious SEM-E cards (so that the machine would be built out of fewer cards). In April 1989 it was decided that the SEM-B version would be limited to about 180 machines, out of a total planned purchase of 750–1000. It seemed likely that the 180 SEM-B versions would be those required for the 30 *Seawolf*-class submarines.

In January 1989 AT&T received a contract to redesign UY-2 using larger SEM-E cards (6 × 6 in). These cards hold 3 times as many microchips and other components as SEM-Bs, and they use high-density gate array and memory devices. The SEM-E version should be small enough to fit aircraft such as the P-3C UPDATE IV. The SEM-B unit is 6 × 2 × 2 ft. The SEM-E unit designed for the P-3 will measure about 4 × 4 × 2 ft and will weigh only a quarter as much as -B. It will incorporate a second processor to correlate acoustic data with nonacoustic (e.g., radar) to distinguish submarines from surface ships. Planned future improvements include a Matrix Array Processor.

The SEM-E prototype should be delivered in April 1990.

◆ ASAP

Martin Marietta's Advanced Systolic Array Processor is proposed as a fast-time analyzer, e.g., for the 20 shore-based ASWOCs. ASAP is a massively parallel processor; the manufacturer claims 300 MOPS on each computer board. The range of equipment based on ASAP includes a generic workstation (SMS-20V), a neural network computer (SNAP), and a variety of special boards. ASAP can be programmed in ADA and can incorporate a VME bus.

Martin Marietta also has a Linear Mapped Array Processor (LMAP), which may be offered as a coprocessor for UY-2.

◆ ASUTAA/P-3C Modernization

In April 1989 it was reported that an upgrade to P-3C aircraft, ASUTAA (Acoustic System Upgrade to ASW Aircraft), would probably be proposed under the FY92 budget. ASUTAA is an attempt to achieve something close to UPDATE IV capability, doubling the DIFAR capability of the P-3C UPDATE III to 32, with 100% memory and 60% throughput reserve, plus post-processing and display capability to fully exploit the new buoys. In contrast, UPDATE IV will be able to handle 54 DIFAR buoys simultaneously. The ASUTAA program was announced in September 1988, and a draft RFP written in 1989. An RFP had

originally been expected in FY90, but reportedly it was delayed so as not to compete directly with the new UPDATE IV program. Early in 1989 it appeared that the program would first be funded in FY92. As of early 1990, it appeared that ASUTAA (UYS-1) would be revived as the P-7/UPDATE IV schedule slipped.

ASUTAA is related to the P-3C Modernization Program, a series of upgrades to system computer (CP-901) and ASP software. The current UYS-1 hardware/software configuration is integrated with Passive Tracking Algorithms (PTA—see the discussion under LAMPS); a 32-channel half-bandwidth capability (Channel Expansion—CHEX); constant resolution (CR) modes; broad-band, digital track (post-CHEX); and 99-channel on-line sonobuoy radio-frequency monitor capability. This program also integrates advanced sonobuoys and detection algorithms, which are contained in the modular-software-design airborne Air Common Acoustic Processing (ACAP), into upgraded P-3C ASP and CP-901 tactical computers.

The FY88 program included completion of P-3C UPDATE III CHEX implementation. The CHEX and ACAP version 4.0 development tests were conducted during the summer of 1989. The next version of ACAP, version 5.0 (constant resolution, broad-band, SSQ-53D buoys), was defined during FY89, and this software was released in June 1989.

The FY89 program included preliminary research work on an airborne transient processor, which was to transition to development in FY91.

◆ IPADS

Improved Processing and Display System, a proposed upgrade to the AQA-7s of Naval Reserve P-3A and -3B aircraft. As of 1990, there is some question as to the future of IPADS, as there have been proposals to retire the P-3As and -3Bs. The counter-argument is that the fleet has insufficient P-3Cs and that it will be many years before enough P-7s appear. Hence the value of at least a P-3B upgrade. IPADS was envisaged as a sixth-generation AQA-7, a less expensive alternative to the UYS-1 of the P-3C UPDATE III. IPADS began as a 1985 congressional initiative, supported by the Naval Reserve Association. Magnavox received the development contract in July 1987 for delivery by May 1990 for July–September 1990 flight tests. Factory tests were completed by the fall of 1989, and the first full suite was installed toward the end of the year. Tests on board a P-3B (using signal generators rather than real inputs) were described in May 1990 as quite impressive.

IPADS is designed to double the number of buoy processing channels (from 16 to 32 LOFAR, or from 8 to 16 DIFAR), to double the number of verniers (to 96), to quadruple the number of DICASS buoys supported (to 4, with extended doppler, equivalent to 8 range-only buoys), and to support a new capability, ERAPS (2 could be processed). Extended doppler was needed to counter faster submarines. IPADS also incorporates the Passive Acoustic Detection and Classification (PADC) algorithms already operational in the active fleet by 1985. Physically, the IPADS system doubled up, providing 4 chart recorders (for LOFARgrams) as well as 2 CRTs. That made for increased reliability since there were 2 entirely independent processing paths.

IPADS has enjoyed very strong support from reservists, but the current (May 1990) official navy position is that it will be too expensive and that the P-3As and -3Bs that might receive it will be retired within 2–3 yr, to be replaced by P-3Cs (when the P-7 is introduced). IPADS was identified by Congress in 1989 as "a matter of special interest." One current issue is whether reserve P-3Bs are in better condition than the active P-3Cs scheduled to replace them.

◆ P-3C UPDATE Programs

The series of P-3C UPDATE programs parallels drastic improvements both in sonobuoys themselves and in the computers processing their data. Many navies (and many U.S. naval reservists) still operate P-3B Orions updated to some approxima-

tion of the P-3C. Late production P-3Bs had a strengthened airframe (135,000 rather than 127,500 lb as a maximum take-off weight), and improvements included a fourfold increase in acoustic processing capacity, a better tactical navigation system, and, in 1981, an IR detector and a Harpoon-missile capacity.

As an indication of the increased computing power of the original P-3C, it was said that the electronics part count in 1 P-3C equaled the total in all 144 P-3Bs. The P-3C could process 16 buoys simultaneously, compared to 8 in a P-3B and 4 in a P-3A. The P-3C had 48 externally loaded sonobuoy chutes (plus 4 reloadable in flight), compared to 9 chutes in a P-3A or -3B. The P-3C also introduced the dual-antenna APS-115 radar, for full 360-deg sea-surface coverage, and used a low-light television instead of the searchlight of the predecessors. The 43rd production P-3C introduced the ASQ-81 MAD.

The UPDATE I program was begun before the first aircraft joined the fleet and entered service in 1974. UPDATE I increased the computer's memory sevenfold (by adding a 384k-auxiliary magnetic drum) and added an additional tactical display for acoustic sensor operators, acoustic processor improvements, a crash locator (beacon), and the Omega navigation system.

UPDATE II doubled the capacity on the acoustic tape recorder (ATR) and added a sonobuoy reference system, the Harpoon antiship missile, and a FLIR to replace the earlier LLLTV. The sonobuoy reference system consists of antennas, located around the fuselage, that locate buoys by recording the phase differences in the signals received by adjacent antennas; the airplane no longer has to overfly buoys to locate them. This system was developed for the S-3A Viking. UPDATE II entered service in 1978 (the first such aircraft joined the training command in September 1977).

UPDATE II.5 replaced some systems with more reliable equivalents (INS, doppler, VHF, VOR/ILS, TACAN, ESM); it integrated aircraft-to-submarine acoustic communications (via buoy); it added a MAD compensation group adapter and a tactical coordinating officer (TACCO) auxiliary IR display; it standardized wing pylons and improved fuel-tank venting.

UPDATE III added an advanced sonobuoy receiver (the 99-channel ARR-78 in place of the 31-channel ARR-72), a single advanced signal processor (ASP: UYS-1), transparent logic units (XLUs), and an acoustic test signal generator (ATSG). An extra lower UHF antenna was added, plus environmental improvements (better cabin-air distribution, a heat-exchanger water spray system, and increased-capacity engine-driven compressors for air conditioning). In this version the airplane has 3 sensor stations (displays) plus a TACCO display. The airplane can monitor 16 different sonobuoy signals on 99 channels. The XLU designation refers to lighter-weight logic units that are functionally equivalent (i.e., transparent) to their bulkier predecessors, using integrated circuit technology. These logic units leave space for later installation of an AYK-14 computer.

UPDATE III incorporates a new 99-channel sonobuoy reference system, ARS-5, replacing the ARS-3 of UPDATE II. In contrast to the earlier reference system, it uses its own computer rather than the overall system computer (ASQ-114). The capacity of the embedded computer makes the reference system a more general-purpose VHF/DF, which can be extended for use in communications intelligence. The manufacturer, Cubic, offers the new version as a stand-alone Sonobuoy Reference System (SRS) with COMINT potential.

In UPDATE III, a digital computer, Proteus (UYS-1, also called ASP), replaces the hard-wired AQA-7. It displays buoy data, either analog or digital, on 2 CRTs, each of which can show 8 buoy channels. Each channel can be broken down into 3 narrow-band (vernier) windows. UYS-1 is heavier than its predecessor, and some reduction in airframe weight (such as by using lightweight floorboards) was needed to compensate. On the other hand, improvements in hardware made it possible to dispense with 1 of the 2 computers originally planned.

Perhaps the most important tactical difference between

UYS-1 and AQA-7 is that UYS-1 provides no paper LOFAR-grams, only a magnetic tape of buoy outputs. In the past, post-mission analysis of grams, generally by eye, often disclosed submarines not detected by crews in flight (e.g., in cases in which a line varied slightly in frequency over time, and thus was obvious to the eye but not to a line integrator). The submarines moved slowly enough that a later flight, briefed to look at the appropriate frequency, could find them.

Continuing work on UYS-1 includes integration with passive tracking algorithms (PTA—see the entry on LAMPS above), broad-band capability, 32-channel half-bandwidth capability (channel expansion), 99-channel on-line capability, and provision for advanced buoys (using modular software).

UPDATE IV introduces a very different distributed architecture, developed by Boeing as UDACS (universal display and control system), initially for the RNZAF Rigel I P-3B modernization program. An UPDATE IV P-3C has 5 UDACS operator consoles containing 68020 microprocessors. The acoustic processor is EMSP (UYS-2). The entire system is tied together by a high-speed maxibus (192 Mbits/sec, using 32-bit words) as well as a 1553B bus. The distributed architecture should make for easier system expansion and modification, and it should also be fault tolerant. The system is expected to have sufficient computing capacity to permit some measure of automatic classification of passive signals.

The new standard UYS-2 processor has increased (currently 99-channel) capacity, presumably to handle both future array buoys and large numbers of low-cost (LCS successor) buoys.

Compared to UPDATE III, UPDATE IV has 2.5 times the acoustic data throughput, 8 times the bulk memory, 30 times the display memory, and 5 times the MTBF. Increased display memory presumably allows an operator to sample the multiple beams available from such new array sonobuoys as HLA and ERAPS. UYS-2 can handle 54 DIFAR buoys simultaneously. The associated high-volume data recorder can accept 30 Mbits/sec for 7.4 hr.

Aside from the acoustic sensors, UPDATE IV aircraft will have an APS-137 ISAR nose radar (there is no tail radar), an AAS-37 FLIR, ALR-66(V)5 ESM, and more precise navigational sensors (Omega/GPS/GPS-aided inertial).

The program began formally with a 1 June 1984 memo by the secretary of the navy. It was approved by the Navy Acquisition Review Council in November 1984. Boeing and Lockheed competed for the contract, and Boeing was awarded a demonstration/validation contract (in competition with Lockheed) in November 1985. The Boeing avionics demonstration began in October 1987, and the company was awarded a full-scale engineering-development contract on 10 July 1987. Lockheed, the P-3C manufacturer, had been responsible for all previous UPDATES. Boeing is to deliver the first UPDATE IV airplane in mid-1990.

In this version the internal arrangement of the airplane is again modified, the TACCO (tactical coordinator), navigator/communicator, and acoustic operators occupying positions similar to those in the P-3B while leaving the nonacoustic operator in the P-3C position. In this arrangement, the TACCO can view all the sensor stations simultaneously, for better coordination.

Existing UPDATE II aircraft are to be modified to UPDATE IV standard, so ultimately the P-3C fleet will consist entirely of UPDATE III and IV. In addition, UPDATE IV is the combat system of the new Long-Range ASW Aircraft, LRAACA (the Lockheed P-7A).

Aircraft are continuously modified, so P-3Cs nominally of earlier UPDATE standard often receive equipment developed for later ones.

See also ASUTAA and IPADS.

◆ TD-1135/A

This Sparton processor is installed in French Atlantic Mk 1 maritime-patrol aircraft, which are fitted with omnidirectional LOFAR processors, providing them with a DIFAR capability. It demultiplexes DIFAR buoy signals to provide LOFAR outputs

from their 2 beams (north-south, east-west) plus their omnidirectional sense outputs, to find target direction. Maximum processor analysis bandwidth is 1 Hz. Time constants: 0.1, 1.0, 10 sec. Minimum MTBF is 1500 hr.

Sparton also manufactures its own low-cost FFT (LOFAR) processor (spectrum analyzer). Input dynamic range is 80 dB. It operates over a frequency range of 14–912 Hz, in 2 bands: 14–114 Hz with 0.25-Hz resolution, 112–912 Hz with 2-Hz resolution. The output is 400 spectral estimates per band.

NONACOUSTIC ASW SENSORS

For ASW radars (for periscope or snorkel detection), see the Strike/Surface Warfare section. Virtually the only current non-acoustic ASW sensors are Magnetic Anomaly Detectors (MAD). However, in the past some ASW aircraft have carried chemical detectors of snorkel exhausts ("sniffers," code-named AUTO-LYCUS in Britain); and Sweden is currently interested in the Australian LADS described below.

MAD is the only sensor on board many helicopters that deliver torpedoes but are directed by shipboard sonar. It is lighter than a dipping sonar, but even so it may be too heavy to combine with a lightweight dipper in a small helicopter. MAD is useful because sonar range often does not correspond precisely to the distance at which the helicopter attacks; the reason is that the sonar beam is bent as it passes through the sea. This consideration applies to the Alouette-III, to the McDonnell Douglas/Hughes 500M (used by Spain), to the McDonnell Douglas/Hughes 500MD/ASW Defender (used by Korea and Taiwan), and to many Lynx helicopters (at least for France, Germany, and the Netherlands). The Royal Navy originally did not carry MAD in its torpedo-delivery helicopters but has added it in the new HAS.8 version. Wasp helicopters apparently lack MAD and are entirely radar/sonar-directed. The Royal Navy originally did not install MAD in its Sea King helicopters (which have dipping sonars and radars), but it was an option (9 MAD kits were supplied during the Falklands War), and it is a feature of the current HAS.6 version. Similarly, MAD was originally an option in Lynx helicopters. British policy would make it unlikely that exported Sea Kings (for Australia, Egypt, Germany, India, and Pakistan) are fitted with MAD.

Reportedly, although the Western powers use MAD as a final-attack confirmation sensor, it is Soviet practice to use MAD instead as a search sensor, flying a tight pattern over the narrow strait through which a submarine is expected to pass. No details of Soviet MAD systems are available.

It is also possible that some nations use magnetic loops for harbor protection; this technology dates from before World War II. The Crouzet MAD buoy would seem to be a current application.

AUSTRALIA

◆ LADS

Not conceived as an ASW system, the Laser Airborne Depth Sounder is an underwater survey system developed to help map the Australian continental shelf. LADS is said to be able to penetrate 50 m of water under all sea conditions, and the device has flown in a Fokker F-27. Reportedly, Sweden has been interested in LADS as a means of detecting small submarines in very shallow water under poor acoustic conditions.

The stabilized LADS laser scans a 240-m-wide swath at a rate of 168 pps, producing a grid pattern of spots 10 m apart. A contract for an operational LADS was awarded to the Australian company BHP Engineering Pty Ltd in May 1989; it is expected to enter RAN service in 1992. LADS was developed during the mid-1970s by the Defence Science and Technology Organization South Australia; the R&D versions (WRELADS) flew about 500 hr from 1981 on.

In April 1988 it was reported that a Larsen 500 airborne Ladar (Laser Radar) bathymeter had been tested by the U.S. Navy Coastal Systems Command, Panama City, and by the U.S. Naval Systems Center at San Diego, and that the device would be

tested as a mine detector in the Persian Gulf. This Ladar was developed by Optech Systems of Downsview, Ontario, and it has demonstrated detection of mines down to about 100-ft depth. It uses a pulsed beam and backscatter to determine the position of the water's surface. The Larsen 500 was developed for the Canadian hydrographic service and has been used for coastal surveys since about 1985. Reportedly, the Ladar has been tested against submarines, torpedoes, nets, mines, and submarine wakes.

There is a long (and unhappy) history of attempts to use blue-green lasers for submarine detection, beginning with the discovery, about 1962, that such lasers could indeed penetrate sea water to a considerable depth. For example, a primitive laser radar figured in advanced U.S. ASW development in the early 1960s; and in the late 1960s such a device, UDACS, manufactured by Kollsman, was publicly described. By that time it was fairly clear that, although the beams were good enough for 1-way communication down to a submarine (albeit not down to great depths), there was not enough of a backscattered signal for useful detection or tracking. Even so, lasers remain attractive in really shallow water.

See also the Northrop ALARMS in the Mine Warfare section.

CANADA

◆ AIMS (ASQ-504)

The Advanced Integrated MAD System was devised by CAE Electronics, Ltd., of Canada. Unlike other helicopter-borne MAD gear, AIMS is carried on board the helicopter; CAE claims that this arrangement frees the crew of the operational restrictions associated with towing a conventional MAD body. Moreover, because the MAD detector is not towed, it is very easy for the helicopter to shift from dipping sonar to MAD operation. The company also claims increased detection range, with a sensitivity of 0.01 gamma in flight. Total weight is 50 lb.

The integration in AIMS is between a very sensitive magnetometer and an advanced compensator to take into account the magnetic field of the aircraft (as well as geological magnetic noise). CAE has been developing sensitive compensators since the 1960s; CAE's AN/ASA-65 is currently the Free World's standard MAD compensator, with 900 units in service.

Detection is by optical pumping of directionally oriented cesium, and interference from the helicopter is canceled out by compensating upon takeoff, the compensating terms being computed in 8 min using an on-board vector magnetometer.

Users include Britain (242 units for Sea King and Lynx HAS.8 helicopters and for Nimrod MR 2 aircraft), and a total of 75 others for Canadian CP-140s, Australian SH-70s, and Australian S-2 Trackers. ASQ-504 was selected for the Turbo-Tracker, currently in Taiwanese service (and probably selected for Turkey), and for the Fokker Maritime Enforcer Mk 2.

See the previous edition for details of the earlier ASQ-502.

ASQ-504. (CAE)

FRANCE

◆ DHAX-1/DHAX-3

DHAX-1, the MAD that is found in the Atlantique Mk 1, uses 4 cesium-vapor paramagnetic resonance cells. DHAX-3 is an improved towed version, for helicopters. It uses 6 rather than 4 cesium-vapor cells.

Applications include French navy (and presumably other) Alouette-III torpedo-delivery helicopters and Saudi Dauphins.

◆ Crouzet MAD Systems

Crouzet uses electronically pumped NMR, in contrast to the optically pumped U.S. and Canadian systems that are based on electron spin resonance. The company claims extreme simplicity and reliability for this approach: there is no optical exciter; and the system uses a liquid rather than a gaseous medium, so there is no vapor to be created before the MAD can operate. Moreover, the output is easily read as a resonant frequency. Crouzet also uses a distinctive signal-processing technique. Instead of threshold detection, the system compares the received signal with a model of the expected target signal, a method the company calls MAD-SADE (Self-Adaptive Detection/Estimation). A simple dipolar model of the target suffices, and the SADE method gives both a confidence level and a fix of the target's position. Experiments both in the Mediterranean and in the English Channel in 1979-80 showed that MAD-SADE improved net detection probability and that, for a given probability, the method increased detection range, so that in about 60% of cases the airplane detected the submarine before passing over it.

The current version is Mk 3, which equips the Atlantique Mk 2 maritime-patrol aircraft and has been tested in Lynx helicopters. The detector is 125 × 1250 mm and weighs 5.5 kg. The entire system weighs 15-20 kg. Sensitivity is within 0.1 gamma. In the Atlantique, twin sensors are used in tandem, to detect any change in the aircraft's signature, canceling it out.

Crouzet MAD sensor, cut away to show its cavity. (Crouzet)

Crouzet MAD Mk 3, showing the probe and its casing. (Crouzet)

This system was tested in 1983, and production began early in 1985. In helicopters, it is towed on a 70-m cable.

In 1989 Crouzet began developing a MAD buoy, seen as a replacement for current passive buoys in the face of future very quiet submarines. The company argues that, even if the Soviets build their craft of nonmagnetic titanium, no submarine can avoid having a large mass of magnetic material, e.g., in the power train. The counter argument is that magnetic detection generally depends on the motion of the submarine relative to the detector. That motion is considerable with an airplane but much less so in the case of a submarine passing a static buoy at low speed. Even so, it is worth recalling that magnetic loops were the standard means of harbor defense before World War II. A submarine passing over the loop generated a current, and that signal could be picked up by a shore station. Controlled mines could be detonated in response. Presumably, Crouzet can do much better in terms of range, given modern highly sensitive techniques of magnetic detection (loops detected at very short range, which was just what was needed to activate the right controlled mines).

INTERNATIONAL

There is an ongoing NATO nonacoustic ASW project, listed by the U.S. government as an FY88 new start. Participants, with expected contributions, are Canada (\$2 million), Germany (\$6 million), Norway (\$10 million), the United Kingdom (\$28 million), and the United States (\$50 million over 5 yr). The first at-sea experiments, in Norway, were conducted in July 1988, with British experiments expected in the summer of 1989. The Norwegian and German navies are presumably particularly interested in nonacoustic ASW because acoustic conditions in the fjords and in the Baltic are so very bad. The brief published description of the program suggests that it is basic physical research, the U.S. government finding it useful to be able to estimate the effect of particular sensor characteristics on submarine detection without having to carry out experiments with actual submarines. That arrangement would, for example, permit a measure of nonacoustic development without having to reveal the sensors and their performance.

JAPAN

◆ HSQ-101

This is the MAD in P-2J aircraft. Presumably, it is related to the U.S. ASQ-10 (the contemporary PS-1 carried ASQ-10A). The later P-3 and SH-60J both carry versions of ASQ-81.

USSR

In contrast to Western navies, the Soviet Union reportedly considers MAD a search sensor, to be used to detect submarines passing through relatively narrow straits. Presumably, this practice explains intense Soviet interest in submarine degaussing. Such a practice would recall the Anglo-American MAD barrier flown over the Straits of Gibraltar during World War II. MAD was used in that case because the layering of the water (caused by the interpenetrating Atlantic and Mediterranean currents) precluded conventional acoustic search.

Reportedly, the helicopter MAD, which is towed on a long cable, is designated APM-60. Effective range is 300–700 m.

UNITED STATES

◆ ASQ-10

The MAD in P-3A/B and late-production S-2 aircraft, ASQ-10 is a saturable-core magnetometer that was introduced about 1960. ASQ-10A was installed in British Nimrod MR.1s (no longer in service).

◆ ASQ-81

Texas Instruments's MAD is currently the standard U.S. Navy system. ASQ-81 uses optically pumped metastable helium. There are 2 configurations, a towed MAD for helicopters and a

ASQ-81 MAD stingers on a line of P-3 Orions. The radomes below the MAD boom carry the rear antenna of the APS-115 radar, so that a 360-deg search can be maintained without the drag associated with hanging a radome below the airplane. (U.S. Navy)

fixed tail MAD for airplanes. Both have been in use since 1970. In 1979 it was reported that ASQ-81 had triple the effective range of earlier MADs, about 3000 vs. 1000 ft. However, other reports suggest that the range of the earlier MAD was only doubled. ASQ-81 incorporates an improved means of maintaining alignment with the earth's magnetic field and has automatic target detection, which ASQ-10 lacks.

Versions are (V)1 for the P-3C, (V)2 for the SH-3H and SH-2D helicopters, (V)3 for the S-3A, and (V)4 for LAMPS-III helicopters.

The helicopter version can be towed at 10–140 kt and can be reeled at 50 or 200 ft/min, the limiting length of the cable being 80–180 ft. ASQ-81 can typically be turned on in 1.5 min, and sensor noise in-flight is generally about 0.24 gammas. Gain can be set at 0.1, 0.2, 0.4, 1, 2, 4, 10, 20, or 40 gammas full-scale.

Users include U.S. and foreign operators of the P-3C and SH-3; the U.S. Navy for the S-3, SH-2, and SH-60; Germany and the Netherlands for the Lynx helicopter; Japan for the HSS-2 helicopter; and Korea, Spain, and Taiwan for the 500M/500MD helicopter.

◆ ASQ-208(V)

This is a digital version of ASQ-81. The microprocessor used to compensate for the aircraft's magnetic field has a 3-channel filtered display and threshold processing. Existing ASQ-81 wiring is retained, but signal recognition is improved. As in the existing unit, targets are automatically detected. However, in this version a range/confidence estimate is provided. Aircraft electronics is simplified. Texas Instruments offers both inboard and towed versions.

The version in the new P-7A has a shorter tail boom than the ASQ-81 of the P-3C because the new airplane has no tail radar antenna and so lacks the metal mass there.

◆ Periscope Detector

In the summer of 1990 the navy was expected to issue a Tentative Operational Requirement for a periscope detector for the SH-60F inner-zone ASW helicopter. There was some speculation that it would be the APS-137 radar, but weight is limited, and the radar would provide much more information than periscope detection requires. SH-60F currently has no radar at all. There has been speculation that the periscope detector might be a blue-green laser, reacting to reflections from the glass in the periscope head. Any periscope detector would be integrated with the helicopter's ASN-123 tactical data system. Re-

portedly, the requirement for the LF dipping sonar to be carried by the SH-60F calls for 3 arithmetic processors, with more computing power than is required for buoys, a dipper, and a radar.

Periscope detection is important for the inner-zone role because many submarine commanders will want 1 look before exposing themselves by firing a torpedo. In difficult sonar conditions, moreover, a submarine is as hampered as a surface ship, so the sub will need to use a nonacoustic sensor (i.e., a periscope) to establish a firing solution. The inner-zone periscope-detection requirement is very different from that imposed on aircraft like the S-3 because it is vital to achieve a very high probability of detection on a fleeting target. In contrast, periscope detection is one of several possible ways an S-3 can detect a distant contact, and the consequence of a failure to detect is not very serious; at such a range the battle group enjoys a layered defense. The SH-60F is the innermost layer of that defense and must, therefore, be extremely effective.

MISSILES

AUSTRALIA

◆ Ikara

Dimensions: length 3.43 m, span 153 cm; overall height 157 cm [135 × 60.2 × 60.8 in]

Weight: about 1300 lb (stated as less than 600 kg)

Warhead: homing torpedo (Mk 44 or Mk 46)

Propulsion: dual-thrust (boost-sustain) Murawa solid-fuel rocket

Speed: subsonic (about Mach 0.75) **Range:** approx 20,000 yd

Ikara is a radio-controlled rocket-powered glider carrying a lightweight torpedo, adopted by the Royal Australian Navy, the Brazilian navy, and the Royal Navy, and sold to the Royal New Zealand Navy. The existing systems employ a single launcher (55-deg launch angle in all cases) and a magazine of reloads. The missile's transponder is tracked by the launching ship, and the missile is commanded to drop the torpedo. The missile then continues in flight, diving into the sea far enough away so as not to interfere with the torpedo's search pattern. To maintain stability after the torpedo has been dropped, the missile deploys 2 small fins at its rear end. The guidance receiver/decoder is housed in the missile's upper fin. The manufacturer claims that hit probability is substantially improved because Ikara continues to receive sonar update information as it flies toward its target. Flight altitude of 300 m [about 1000 ft] is maintained by barometer.

In the British ships, 1 of which is now in New Zealand service, missiles are stowed in 2 parallel rows, without their wings and tails. Each is on a shock-mounted stool, is extracted manually by an overhead grab on a monorail in the magazine's roof, and is lifted onto a trolley running between the rows. The missile is raised by hoist to an assembly room on the upper deck immediately forward of the bridge and then finned before being moved tail-first onto the launcher. Since the missile has no de-

Ikara. (British Aerospace)

Ikara. (RAN)

icer, it cannot be stored on the launcher for very long, but missiles can be stored in the assembly room.

Ikara was inspired by (but is unrelated to) the French Malafon. Work began in 1959, and the basic design was settled by mid-1960. Trials (using a short-burn solid-fuel motor) began in February 1961, and the first all-up prototypes were ready at the end of that year, using the Murawa boost-sustain motor. The first sea trials, using Mk 44 torpedoes, were conducted early in 1964 on board HMAS *Stuart*. Britain had shown interest in the program from the start, and an Admiralty mission arrived in Australia in December 1964, a formal agreement being signed in March 1965 for the missile to be used on board the new *Bristol*-class missile destroyer. At this time the Royal Navy expected to use a new lightweight torpedo, Mk 31, which was substantially heavier than the U.S. Mk 44 adopted by the Australians, and a new version of Ikara had to be designed. At this time the missile was modified so that it could launch any of 4 alternative payloads, 1 of which was a high-explosive bomb. Another was probably a nuclear depth bomb; the other 2 would have been alternative homing torpedoes. British Ikara trials began in April 1967. There was also U.S. interest; in 1966 there were joint U.S.-Australian trials off Hawaii, during which Ikara-borne torpedoes hit 2 submerged submarines operating at 9 kt.

Ikara is currently used by the Australian, Brazilian, and Royal New Zealand navies. The Brazilian version is called BRANIK (Brazilian Ikara). The Royal Navy adopted Ikara as GWS.40, but it discarded its last 2 Ikara ships during 1989; the New Zealand ships use the British version. BRANIK uses a lightweight semi-automatic launcher. Without Ikara, the Royal Navy no longer has any all-weather standoff ASW capability.

There are several versions. The original Australian Mk 1 and British Mk 2, neither of which entered service, were designed to carry the abortive British Mk 31 lightweight torpedo. Mk 2 and 3 (British and Australian, respectively) carry the U.S.-supplied Mk 44, and Mk 4 and 5 the U.S.-supplied Mk 46. One objective of the Ikara redesign program was to simplify the missile so that it could carry a wider variety of lightweight torpe-

Ikara on board the Australian destroyer *Brisbane*, on the small launcher on the side amidships. The main radars are SPS-40 (foremast, with SPS-10 below it) and SPS-52 (the flat plate aft), with 2 SPG-51 missile-guidance radars below. The big radome atop the bridge is the Ikara guidance link. (U.S. Naval Institute)

does with less variation. The thousandth Ikara was delivered in 1977.

Several new versions have been proposed, none successfully. Basset (1981) was a boxed version. Super Ikara was to have been a boxed version with folding wings and a turbojet power plant, for longer loiter near the target. A prototype, produced in collaboration with British Aerospace, flew in September 1986, but in July 1987 the Australian partner, Government Aircraft Factories, was dissolved. Super Ikara differed from the original version in that control could be passed to a helicopter near the target. The helicopter could, therefore, devote its entire payload to sensors and fuel. Super Ikara was originally a collaborative project with OTO-Melara, but that company dropped out to work on MILAS (see the French section below).

CHINA (PRC)

◆ CY-1

Dimensions: 41 cm × 5.5 m [16.1 × 216.5 in]
Weight: 700 kg [1540 lb] **Propulsion:** rocket
Range: 5–18 km [5500–20,000 yd]

This ballistic antisubmarine missile was first displayed at ASIINDEX in November 1986. No details were given, other than that CY-1 will be fired from a multicell launcher on board surface ships. Externally the missile resembles ASROC, and CY-1 is credited with ASROC-like performance. However, unlike ASROC, CY-1 reportedly may be carried by helicopters and maritime-patrol aircraft. It is not clear how the missile would be targeted in that case: perhaps the Chinese expect to operate aircraft in cooperation with submarines that would provide target data. Nor is it clear whether the Chinese currently have an MF sonar suited to such a weapon, and no Chinese warship carries the requisite launcher. However, drawings of a destroyer offered for export do show a pepperbox launcher. In 1988 the Chinese displayed 2 new sonars, perhaps operating at lower frequencies, at ASIINDEX in Beijing (ESS-1 and -2).

FRANCE

◆ Malafon

Dimensions: 651 × 5877 mm; span 3190 mm (booster: length 2135 mm, span 1800 mm) [25.6 × 231.4 × 125.6; 84.1 × 70.9 in]
Weight: 1000 kg [2200 lb] after booster separation; booster: 330 kg [727 lb] **Warhead:** L 4 homing torpedo
Propulsion: glider, after boost; booster burn time 2.8 sec, impulse 35,000 kg-sec [77,140 lb-sec]

Speed: at end of boost, 280 m/sec, decreasing to 100 m/sec during flight [918 ft/sec, decreasing to 328 ft/sec]
Range: 3000–15,000 m; maximum 20,000 m [3300–16,400 yd; maximum 21,900 yd]

Malafon is a ship-launched standoff weapon carrying an L 4 homing torpedo and using a gun direction radar for guidance. The missile is tracked using 2 flares in its wingtips. Malafon is a glider gyro-stabilized in roll and pitch; at the end of its flight (800 m short of the predicted position of the submarine), the missile is commanded to level off, the torpedo is unlocked, and the missile is braked by parachute. The torpedo continues on and enters the water.

Malafon is stowed without its wings and tail fins, the booster fins being folded. One missile is usually held on the launcher, ready to be fired, and the missile can be launched within 30 sec. A second launch can follow 60 sec later, and then the firing rate can be up to 1 every 90 sec. Typically a ship carries 13 missiles; the launcher proper weighs 10,500 kg.

Malafon's development began in 1956, and the missile was first tested in 1958, with sea trials following in 1962 on board the experimental destroyer *La Galissonière*. Initial operational tests were conducted in 1964. As of about 1978, it was reported that 370 Malafons were in service and that further missiles were being manufactured to replace those expended in training. Eight ships now carry Malafon, the last system having been installed over a decade ago. With Masurca, Malafon is a survivor of the French post-World War II naval missile program.

Malafon's guidance systems were modernized in 1986–87 by SENA and now use solid-state components instead of vacuum tubes. As a result, Malafon should remain in service to the end of the century.

Malafon on its launcher. Reloads are stowed in the deckhouse on the right. (U.S. Naval Institute)

◆ Malafon Replacement (MILAS)

Dimensions: 460 mm (1060 mm with boosters) × 6 m [18.1 × 41.7 × 236 in] **Weight:** 800 kg including torpedo [1760 lb]
Warhead: Murène or A290
Speed: 300 m/sec at 20 m in altitude [984 ft/sec at 66 ft]
Range: 40 km (time from launch to splash at about 20 nm is less than 3 min) [44,000 yd]

In 1986 two teams competed to produce a replacement for Malafon that would carry the new Murène lightweight torpedo (and, for export, a variety of equivalent foreign weapons). The basic requirement was formulated in the late 1970s, after the French naval staff had decided to abandon such weapons in favor of helicopters. Tactical experience showed that a helicopter's

MILAS. [Author]

reaction time was about 15 min, and the French navy asked for a CZ standoff missile.

Matra and OTO-Melara offered a modified Otomat Mk 2, with a range of over 40 km, designated MILAS. The missile's warhead is replaced by a lightweight torpedo. Like Otomat, MILAS can receive mid-course guidance instructions. Recent accounts of MILAS mention a Franco-Italian requirement formulated in 1985, but it is not clear whether this formulation was the beginning of the OTO Melara-Matra project or an official decision.

Aerospatiale offered a torpedo-carrying Exocet, about 6.38 m long, which could be launched from a submarine as well as from a surface ship. With a suitable booster, this Exocet could be fired by ASW helicopters and airplanes.

MILAS was chosen in the summer of 1987, and a French-Italian development MoU was signed in September 1987. Given its limited dimensions, MILAS will probably be carried in a deck container (canister launcher) rather than in the magazine used for Malafon. The first production MILAS is to be delivered in 1992, and the French and Italian navies have both indicated an initial requirement for 200.

Maximum range is nearly 60 km in a straight line. For a flight of 35 km, the elapsed time is less than 3 min. Cruise altitude is 200 m. It is estimated that in-flight course corrections can increase the probability of target acquisition by as much as 15% at long range. After turbojet cutoff, the delivery system, retarded by a parachute, separates from the torpedo, and another parachute lowers the torpedo into the water.

MILAS will arm French F67-class destroyers (probably 12 launch units each), replacing Malafon; MILAS will also arm 7 C70 during mid-life refits (6–8 launch units each) and will be added to Italian *Maestrale*s and other major Italian warships during their mid-life updates. All future French and Italian ASW warships will be armed with this weapon.

As of mid-1989, aerodynamic testing had been completed, and about 10 firing trials (without torpedo) were to be conducted in 1990–91; the missile can be in service by about 1994. Besides France and Italy, another NATO navy is reportedly interested.

INTERNATIONAL

◆ NLCAW

The NATO low-cost ASW weapons project was inspired in part by the experience of the Falklands. False contacts were numerous, and in many cases the only sure means of classification was to fire a weapon (a real submarine runs away). Since weapons are increasingly expensive, the preferred technical approach seems to be a rocket- or mortar-thrown intelligent depth charge or low-cost, low-performance torpedo. The program also presumably builds on work done during the 1980s on a homing depth charge, to be fired from the standard Terne or Bofors 375 launcher. The system consists of a simple rocket or mortar (i.e., ballistic) launcher, a semi-intelligent weapon, and an FCS. In at least some cases, the weapon is also to be deliverable by helicopter.

A former European participant in the program considered it remarkable that, a year after laughing off the requirements (Pk,

range, price), industry was able to meet them. The surprise was just how many weapons already met the specifications; the NATO group brought the weapons makers together with those producing the standoff missiles or rockets. For example, Whitehead produced a torpedo with a diameter of about 8 in, with a very reasonable kill probability, and with a unit cost of about \$50,000; 3 torpedoes could be fired out of a standard Bofors 375 mortar, and the Whitehead weapon was not really too much larger than a standard A-size sonobuoy. The existence of really cheap ultra-lightweights called into question the rationale for standard lightweight torpedoes.

Sweden tried to join the group with its Elma, but it was rejected because its range was much too short. The most widely used unguided weapon, the Bofors 375, was rejected because it was not sufficiently accurate; its 6-shot salvo was credited with a Pk of less than 0.5, although it was considered useful as a means of forcing a submarine to flee.

The NATO project (under Project Group 34) was formulated in 1989, the partners at that time being the United States, Norway, Germany, and Italy. As of 1990, reportedly 12 teams (led by Diel, AEG, MBB, NFT, Whitehead, Honeywell ELAC/Honeywell USA, Krupp MAK, Royal Ordnance, Martin Marietta, General Dynamics, FMC, Loral) had submitted concepts, and 6 had been labeled "serious." Two of the teams include a German prime contractor. One of them consists of KAE, Dynamit Nobel, Dyno, and Lockheed, with Marconi as consultant. It will presumably use a variant of the Lockheed Lightweight Torpedo described in the U.S. torpedo section, below. Whitehead is developing an inexpensive lightweight torpedo to meet the NATO requirement (see LCAW, below).

USSR

◆ SS-N-14 (Silex)

Dimensions: length 7.6 m [25 ft] **Warhead:** homing torpedo
Propulsion: solid-fuel rocket **Speed:** Mach 0.95
Range: 30 nm (4 nm minimum)

The Soviet equivalent of Malafon or Ikara, SS-N-14 is a powered missile that carries a homing torpedo. SS-N-14 might be considered the direct nonnuclear successor to FRAS-1, arming most Soviet ASW ships of destroyer or greater size. Except for

A Krivak-class frigate shows her quadruple SS-N-14 launcher, with a pair of RBU-6000s just abaft it. The 2 shrouded antennas on lattice mast above the bridge are the Eye Bowls controlling the SS-N-14 missiles; above them is a Don Kay surface-search radar, with Head Net C at the masthead. The shrouded object immediately over the bridge is Pop Group, to control SA-N-4 anti-aircraft missiles. (U.S. Naval Institute)

on the *Kirov* (which has a unique reloadable twin launcher), SS-N-14 is carried in 4-missile sets.

When the launchers first appeared, in the Krivak class, this missile was identified as a short-range antiship missile and designated SS-N-10. No such weapon exists, although SS-N-14 has a secondary antiship capability that uses an explosive charge in the airframe. In 1983 it was reported that SS-N-14 carries an alternative nuclear warhead, presumably a nuclear depth bomb, of about 5-kT yield.

The missile is command-guided, either by a special antenna (Eye Bowl) or via a set of Head Lights SAM control radars. Flight altitude is reportedly about 80 m [about 260 ft]. Krivaks have an MF sonar, which is unlikely to provide data sufficiently accurate for attack beyond about 10,000 yd (as in the case of the U.S. ASROC). Ships equipped with lower-frequency sonars should be able to mount attacks at about twice that range. If these ships detect targets at CZ range (20–35 nm, depending on water conditions), then probably helicopters with sonobuoys or dipping sonars must reacquire the target before the ship fires.

◆ SS-N-15 (Starfish)

The Soviet equivalent of the U.S. SUBROC is armed only with a nuclear warhead. SS-N-15 was copied from the U.S. weapon, reportedly compromised about 1964, and was probably intended as the primary weapon of the Victor-I-class submarine. Maximum range is 21.6 nm.

If SS-N-15 is a SUBROC equivalent, then its rocket is fired after it is ejected from the torpedo tube. Guidance is inertial, based on prelaunch sonar data (U.S. practice was to track the target passively, then use a single ping to obtain an accurate range; this method reduced the target's warning time). In the U.S. weapon, the warhead had to be nuclear because the combination of the single ranging ping and the sound of the motor firing underwater provided the target with some warning. Analysis showed that a submarine could escape the acquisition range of a Mk 44 torpedo launched in this way, but that it could not escape the lethal volume of the warhead. SUBROC was initially conceived as a shore-bombardment weapon, and it is possible that SS-N-15 has a secondary shore-bombardment or antiship capability. In the 1960s the antiship threat presented by a possible Soviet SUBROC was a major factor in driving U.S. anti-missile-defense projects.

◆ SS-N-16 (Stallion)

This missile is a dual-capable successor to SS-N-15. Because all Soviet homing torpedoes are substantially larger and heavier than the U.S. lightweight torpedo that SUBROC could carry, SS-N-15 is almost certainly much larger than a 21-in tube and is probably responsible for the adoption of the 65-cm torpedo tube in recent Soviet submarines. The shift from SS-N-15 to -16 may be responsible for the greater length of the Victor-II-class submarine, to accommodate a better combat system.

Maximum reported range is 54 nm, far beyond any usable acoustic range. This figure may have 2 quite different significances. One is that a missile capable of flying 54 nm will reach tactical ranges (perhaps of the order of 10 nm) quickly enough to keep the prospective target within torpedo-acquisition range. The other would be that the weapon might have an alternative antiship or even shore-attack role.

UNITED KINGDOM

◆ SUGW

A British staff requirement formulated about 1986 called for an Ikara successor (Surface-to-Underwater Guided Weapon), a weapon that could exploit towed-array detection and that was, therefore, capable of attacking out to the second CZ. In the fall of 1987, however, the Ministry of Defence announced that this program had been shelved for at least 3 yr because of a lack of funds.

The 2 alternatives under consideration in 1986 were Super Ikara and Tarpon (McDonnell Douglas/Marconi), the latter us-

ing Harpoon to project a Stingray torpedo. Tarpon has also been suggested (in the United States) as an ASROC or SUBROC successor. Reportedly, Dowty and McDonnell Douglas were also proposing a vehicle that would lay sonobuoys at long range, making it possible for a surface ship to prosecute contacts at or beyond the CZ even if she could not launch a manned helicopter.

UNITED STATES

All SUBROC missiles have been retired; the last was operational in the fall of 1988. These missiles were presumably retained for a time in reserve since the warhead (W45) was retired only in the fall of 1990. For details of SUBROC, see the first edition of this book.

◆ ASROC (RUR-5A)

Dimensions: 13.25 × 177.4 in (33-in fins)

Weight: Mod 3, 949–57 lb; Mod 4, 1071–73 lb

Warhead: Mod 3, Mk 44 torpedo; Mod 4, Mk 46 torpedo; Mod 5, Mk 17 Depth Bomb (nuclear: W44 warhead)

Range: maximum about 10,000 yd [minimum range is 900 yd for the torpedo version and 3500 yd for the nuclear version]

The Antisubmarine Rocket is the current U.S. standoff ASW weapon for surface ships; ASROC has also been transferred to many Allied nations, in many cases on board ex-U.S. ships. It carries either a Mk 46 torpedo or a Mk 17 nuclear depth bomb; existing ASROCs will probably be upgraded to carry Mk 50 lightweight torpedoes.

ASROC was conceived as part of a system including a reliable 10,000-yd sonar, SQS-23. The later SQS-26 has higher per-

A torpedo-carrying ASROC being fired. (U.S. Navy)

formance; and an extended-range version, ERA, was designed to exploit its greater direct-path range (nominally about 20,000 yd). Although ERA was tested in 1967, it was never produced, presumably because it had too low a priority in the face of severe fiscal problems during the Vietnam War. VLA is, in effect, a vertically launched ERA, although the technical details are very different.

The usual Mk 112 launcher is trainable, but it fires at a fixed 45-deg elevation, 2 of the 8 cells elevating together. Range is determined by fixing the point of booster separation.

ASROC can also be fired from the Mk 10 launchers of *Belknap*-class cruisers and of the *Truxtun*, and from the Mk 26 launchers of *Virginia*-class cruisers and early Aegis cruisers; these launchers, too, fire the rocket at a fixed angle of elevation. In *Knox*-class frigates 2 cells of the ASROC box were modified

A standard ASROC box launcher on board the Japanese destroyer *Haruyuki*, 1989. (W. Donko)

to fire Standard surface-to-surface (later Harpoon) antiship missiles.

About 12,000 ASROCs were manufactured between 1960 and 1970, when production ended.

The nuclear version of ASROC (W44 warhead) was retired by September 1989.

♦ Vertical Launch ASROC (VLA)

VLA is ASROC modified for firing by the new vertical-launching system (Mk 41). The initial units will be produced by Loral, with Martin Marietta as the designated second source. Compared to the original ASROC, VLA has increased range (to exploit the greater direct-path range of SQS-53, compared to SQS-23) and can carry a somewhat heavier payload (Mk 46 or Mk 50 homing torpedo). VLA or some equivalent is essential because ships fitted with vertical launchers generally cannot accommodate the earlier ASROC box launchers; without VLA these ships would not have any all-weather standoff weapon.

Dimensions are 14.1 × 200 in, and weight is 1650 lb. These figures are still within the limits imposed by the existing ASROC and Mk 26 launchers. As of 1987, the navy demanded a minimum range of about 5 kyd and a maximum range of at least 15 kyd. The first all-up demonstration/validation shot was fired at China Lake in July 1984.

The basic design was carried out by the navy, with development by Goodyear (whose naval division was later sold to Loral). The missile is pitched over into its ballistic trajectory by autopilot-controlled thrust vectoring. As in ASROC, trajectory is controlled further by ejecting the booster at the appropriate moment, the torpedo payload continuing on a ballistic path into the water.

This missile had been expected to enter service in 1989, but Congress authorized none in either FY88 or FY89, the FY89 request for 340 being deferred to FY90. In 1988 Sea Lance was adopted as the single standoff weapon for both submarines and

VLA MISSILE SYSTEM

VLA operating sequence and missile. (Martin Marietta)

surface ships, and VLA was demoted to interim status (Congress ordered 300 bought). However, VLA was revived in 1990 as the primary surface-ship standoff ASW weapon, Sea Lance (both versions) having been canceled.

Japan has also ordered this weapon for its new Aegis-equipped destroyers (which lack conventional ASROC box launchers).

Combined at-sea development and operational tests of VLA were conducted by the *Hewitt* in December 1988.

♦ Sea Lance (UUM-125A)

Dimensions: 16.0 × 228.0 in (capsule: 20 × 244.23 in)

Weight: 2282 lb (total with capsule: 2793 lb)

Warhead: Mk 50 torpedo

Range: probably comparable to SUBROC

The digital replacement for SUBROC, Sea Lance was developed as the ASW standoff weapon (SOW). For a time, it appeared possible to combine SOW with the VLA requirement, to produce a Common ASW SOW; but this approach proved impractical, and the 2 programs were separated in 1982. In 1988, however, the 2 programs were again being merged. Stated requirements included the ability to launch at up to 80% of a submarine's test depth, as well as stealthy operation. It was decided, therefore, that Sea Lance would be launched in a capsule, like the Tomahawk cruise missile, emerging only after reaching the surface. Such buoyant launch is much quieter than the use of a rocket motor underwater.

Flight characteristics have not been released, although ranges as great as 105 nm (3 CZs in the Norwegian Sea) have been reported (e.g., by the developer, Boeing, in a brochure). These ranges are almost certainly aerodynamic rather than effective tactical ranges. It is much more likely that the effective tactical range is much like that of SUBROC, dictated by a submarine's ability to track a target (i.e., by direct-path range). The long reported range would correspond to the very energetic rocket motor required to minimize the flight time to the targeted submarine.

Sea Lance has a role very different from that originally envisaged for SUBROC. As Soviet submarines become quieter, it becomes less and less likely that they will be tracked at very long ranges. However, U.S. submarines will operate in or near Soviet

Sea Lance capsule being loaded onto an attack submarine. The submarine's HF sonar transducer is in the forward edge of the sail, and the surface-search radar is atop the sail. (Boeing)

Sea Lance prototype in flight, January 1989. The payload must be shrouded (which is not the case in ASROC) because the missile is so fast. (Boeing)

waters in wartime. Soviet submarine commanders will know that, if they run at high (loud) speed, or if they use their active sonars, they will provide the necessary targeting data. Thus, the

existence of a submarine standoff weapon may in itself inhibit Soviet submarine commanders from running out into their patrol areas at high speed, or, for that matter, from seeking out U.S. submarines by active sonar search. Given this mode of operation, Sea Lance had to be usable without high-level authorization, i.e., the weapon had to be nonnuclear. In December 1986 the development program was reversed, the primary version switching from a nuclear depth bomb to a Mk 50 torpedo payload. Presumably, this choice was justified, at least in part, by the demonstrated lethality of the Mk 50 warhead and by the longer acquisition range associated with Mk 50, as compared to Mk 46.

One important argument in favor of the use of Sea Lance on board surface ships is that the missile's long maximum range can be exploited by using a LAMPS helicopter as a targeting platform. The helicopter localizes the submarine target within the box defined by the ship's long-range sensor, and the ship can fire multiple rounds into that box. In this way the overall effectiveness of the ship/helicopter weapons system is not limited by the torpedo-carrying capacity of the helicopter, and the helicopter can gain endurance by carrying extra fuel.

Boeing received the Sea Lance contract in April 1981, and as of 1988, plans called for 2400 missiles. Boeing received a full-scale development contract in July 1986. Flight trials of the Sea Lance missile began at White Sands in the summer of 1988, and the first successful sea test (dynamic launch, all-up except for a short-burn motor) was fired from San Clemente on 22 February 1989. The first full-up full motor test was scheduled for White Sands in the summer of 1990.

The program was delayed during FY89, presumably in part because of the dual-use decision. It was then canceled late in 1989. Explanations vary; originally it was merely stated that the budget was too tight to accommodate a weapon otherwise clearly desirable. Then there was a suggestion that Boeing had asked for a 2-yr delay (and about \$900 million more). However, advocates of Sea Lance argued that the delay was really more like 2 months, and the additional cost only a few million dollars. Early in 1990 an OSD official suggested that the Sea Lance mission might be shifted to a modified Tomahawk, and there was also an official suggestion that Mk 50 might be modified to replace Sea Lance. Such comments suggest that cancellation was originally a bureaucratic error, made on the misunderstanding that Sea Lance was primarily a nuclear missile, and that later explanations were attempts to avoid embarrassment.

Although DoD canceled Sea Lance, in mid-1990 both the House and the Senate proposed to restore funding in the FY91 budget.

TORPEDOES

CHINA (PRC)

The current production antiship torpedoes are designated Yu (Fish) 4A and 4B. They are officially described as derived from foreign torpedoes, most likely Soviet types. Development was conducted by Xian Independent University, and these weapons were standardized in February 1984.

In 1988 it was reported that the PRC program to manufacture the U.S. Mk 46 Mod 5 has been delayed because of difficulties in translation to metric units. Reportedly, the current PRC lightweight torpedo is the Italian A-244, about 40 of which were acquired.

In January 1990 the PRC announced first tests of a new Type C43 heavy torpedo off the Fujien coast in the Taiwan Straits. It is said to have wire mid-course and active/passive terminal homing, and it presumably uses an Otto engine similar in concept to that in the Mk 46. C43 is a dual-purpose torpedo, which can be fired by surface ships and submarines. It was developed by the Electronics Industry Division under the Chinese Academy of Sciences (Academia Sinica), with technical assistance reported from IBM, NEC, and Wang Computers. As of mid-1990, C43 is not yet in production, but it is presumably intended to replace the current Yu 4/5.

There was no previous public mention of any PRC submarine-launched antisubmarine torpedoes.

FRANCE

An indication of the current production rates of torpedoes for the French navy is that the 1984–88 budget called for orders for 70 torpedoes (presumably all heavy) in 1984/85 and for an additional 190 in 1986–88, with 278 torpedoes delivered in 1984–88, and another 170 after 1988. Presumably, these figures are all heavy torpedoes since Murène is not yet in production. Reportedly, the initial production rate for Murène is 20 per year.

◆ E 12/E 15

	E 12	E 15
Dimensions:	550 mm × 7.0 m [21.7 × 276.0 in]	550 mm × 5.9 m [21.7 × 232.3 in]
Weight:	1650 kg [3637 lb]	1387 kg [3057 lb]
Speed/Range:	25 kt/12,000 m [13,000 yd]	25 kt/12,000 m [13,000 yd]
Warhead:	330 kg [727 lb]	300 kg aluminum tolite or HBX-3 [660 lb]
Power Plant:	battery	nickel-cadmium battery, 50-kW motor

E 15 is the export version of E 12. E 12 was developed on the basis of wartime German technology (such as the T-5 homing torpedo) that fell into French hands in 1944–45. Both E 12 and E 15 are CIT-Alcatel's submarine-launched passive-homing torpedoes, for use against surface ships or submarines at periscope depth (target depth down to 18 m [59 ft]). The torpedo has a contact or magnetic fuze. A fire-control solution is required to bring the torpedo within about 700 m [770 yd] of its target. The E 15's homing system duplicates that of E 14; the hull is a lengthened form of that of the E 14.

This torpedo was placed in production after another submarine torpedo development program, V (for *vitesse*) 11, had been abandoned in 1958. V 11 was a fast, straight-running, oxygen-alcohol torpedo intended for a range of 15,000 m [16,400 yd] at 55 kt.

See the E 14 entry for a modification program.

◆ E 14

Dimensions:	550 × 4279 mm [21.7 × 168.5 in]
Weight:	927 kg [2043 lb]
Speed/Range:	25.5 kt/5000 m [5500 yd]
Warhead:	200 kg tolite [440 lb]
Power Plant:	nickel-cadmium battery (40 kW)

The submarine-launched passive-homing torpedo by CIT-Alcatel is in effect a smaller version of E 12, designed primarily to arm the small French antisubmarine submarines, now extinct. E 14 uses contact or passive magnetic proximity (range about 4 m) fuzing. This weapon is intended for use against surface ships or shallow submarines (e.g., submarines at periscope depth), using settings of 6–18 m [20–60 ft] for the depth of its run; E 14 can run at depths as great as 300 m [984 ft]. Compared to E 12, E 14 trades endurance for a more powerful warhead.

This torpedo has the same propulsion and hull as L 3, but E 14 homes passively, using a bank of 4 transducers operating by phase comparison within a 1-kHz bandwidth. Enable range is 350 m [383 yd]; average acquisition range is 500 m [550 yd]. The battery has 76 cells (E 15 has 120).

E 14 was introduced in 1960, and about 100 were made.

DCN is developing a modification kit for the E 14, E 15, and L 3 torpedoes. The existing nickel-cadmium battery is replaced by a silver-zinc battery (which doubles the range); the propulsion system is improved (to add 10 kt); and the homing system is replaced (AH 8 vice AH 7, for 50% greater acquisition range).

In 1990 CNIM announced that it was modernizing French L 3, E 14, E 15, and Z 16 torpedoes to E 15 Mod 2 standard, adding the AH 8 homing head and silver-zinc primary battery already operational on the F 17 Mod 1 torpedo. As modified, the torpedo searches at 25-m depth and has a detection range of 2000 m; attack depth is 6–18 m (presettable), and maximum depth is 300 m. Performance is 31 kt/12,000 m, and the warhead

is 300 kg of tolite aluminum. Those torpedoes are lengthened to 5900 mm [232.3 in].

◆ E 18

Dimensions:	533 × 5230 mm [21 × 205.9 in]
Weight:	1230 kg [2711 lb]
Speed/Range:	35 kt/18,000 m [19,700 yd]
Power Plant:	battery

E 18 is a dual-purpose torpedo for surface ships. E 18 has passive homing (i.e., usable against a noisy submarine) and a maximum depth of 500 m [1640 ft].

◆ F 17

Dimensions:	550 mm × 6 m [21.7 × 236 in]
Weight:	1410 kg [3108 lb]
Speed/Range:	35 kt/18,000 m [19,700 yd]
Warhead:	250-kg HBX-3 (equivalent to 500-kg TNT) [551 {1100} lb]
Power Plant:	zinc-silver oxide battery (contraprops)

This wire-guided dual-purpose torpedo was introduced in 1973 by DTCN. F 17 has active-passive terminal homing (active for antisubmarine, passive for antiship). There is a special shallow-water mode that can be preset before launching (sonar scan is limited in elevation). The stated diving limit is 600 m.

F 17 Mod 1 has dimensions of 550 × 5900 mm [21.7 × 232 in], has a speed/range of 35 kt/22,000 yd, and can run at depths as great as 500 m [1640 ft]. This torpedo is launched from both submarines and surface ships.

F 17 Mod 2, in service 1988, has dimensions of 533 × 5384 mm [21 × 212.0 in], a weight of 1397 kg [3079 lb], and a speed/range of 40 kt/20,000 m [22,000 yd] (because of its more powerful—85 kW—motor). Maximum operating depth is 600 m [1968 ft].

F 17P Mod 2, in service 1985, has dimensions of 550 × 5620 mm [21.7 × 221 in], a weight of 1320 kg [2909 lb], and a speed/range of 35 kt/32,000 yd. 17P Mod 2 is launched from submarines only, against surface ships.

Spain has an agreement with SOFMA to convert 16 E 15 torpedoes to F 17 Mod 2 standard.

Thomson Sintra has tested fiber-optic (as opposed to the current wire) guidance for torpedoes. The first trial, using 2 km of cable, occurred on 22 December 1987; a second trial (20 km) was conducted on 9 February 1988. The tests were mainly to

F 17 wire-guided torpedo. (Thomson Sintra)

F 17 torpedo tubes on board the Saudi frigate *Al Madinah*. Western navies have found it is easier to operate a surface-launched wire-guided torpedo from stern tubes, the wire running out as the ship steams away. That arrangement applies also to several U.S. attempts to combine wire guidance with surface ships and to the Italian A-184. (Thomson Sintra)

determine whether information could be transmitted over very long distances without error; in these tests the information transmission rate was 41 Mbits/sec. Thomson Sintra claims that these were the first experiments of their type.

The main current version is F 17 Mod 2, which has a speed of 40 kt and can operate below 600-m depth. The torpedo carries 18,000 m of guidance wire. A typical French submarine torpedo tube has a dispenser for another 4000 m (8000 m in German-built submarines such as Type 209). Mod 2 can be launched at any depth down to 400 m, and it searches at 1 of 4 depths (attack/ceiling depth, preset at 6–20 m, 30 m, 100 m, and 200 m). It can be set to attack surface ships at a depth between 6 and 20 m. Max trim angle is ± 40 deg, and max turn rate is 12 + deg/sec. The warhead is 250 kg of HBX-3.

The original version, Mod 1, was passive only. It was developed into F 17P (polyvalent, i.e., active or passive) and also into a reduced-cost passive F 17S1. F 17P in turn was developed into Mod 2 (which equips current French submarines) and into a less expensive active/passive F 17S2. Mod 1 and S1 are effective only against surface ships. S1 and S2 have speed limited to 35 kt, and operational range 18,500 rather than 20,000 m. S1 costs 60% as much as Mod 2, and S2 costs 75% as much. S1 also has reduced countermeasure resistance.

◆ L 3

Dimensions: 550 × 4320 mm [21.7 × 170.1 in]
Weight: 910 kg [2006 lb] **Speed/Range:** 25 kt/5000 m [5500 yd]
Warhead: 200-kg HBX-3 or TNT [440 lb]
Power Plant: nickel-cadmium battery (40-kW motor, 2 contra-props)

L 3 is an active acoustic-homing, submarine-launched, anti-submarine torpedo (for target speeds up to 20 kt) that uses a contact or active-acoustic (range 20 m) fuze. L 3 is usable in depths down to 300 m [984 ft]. The torpedo's angle of pitch is limited to +10 to -40 deg. Acquisition range is 1000 m [1100 yd], using a 32-kHz active seeker. The torpedo runs at 30 m [98 ft], executing a sinuous (snake) search after reaching its enable point.

This torpedo was introduced in 1960, and it was first displayed in 1968. L 3 was manufactured by DCN, which now offers a modification package (see E 14 entry above) including a new homing device, AS 15, instead of the earlier AS 3. A 21-in [533-mm] version was designed but never entered production. This version was 4318 mm [170 in] long and weighed 900 kg [1983 lb]. About 600 L 3s were made.

L 3 replaced an earlier antisubmarine torpedo, the straight-running K 2 (oxygen-alcohol propulsion, speed/range 50 kt/1000 m [1090 yd], maximum depth 300 m [984 ft]). K 2 was a straight-runner, launched in salvos of 3 with preset tune (i.e., depth) fuzing. It was the equivalent of such contemporary rocket-fired depth charges as the British Limbo, the Italian Menon, and the U.S. Weapon Alfa, using a torpedo power plant instead of a rocket to propel the torpedo to the desired point. Dimensions were 550 × 4400 mm [21.7 × 173 in]; weight was 1104 kg [2433 lb] with a 280-kg warhead [617 lb]. K 3 entered service in 1956, and it remained in service until about 1976.

French surface ships generally carry a combination of L 3 (short-range) and L 5 (long-range) torpedoes, both launched by compressed-air catapults rather than from torpedo tubes (2 in an A69, 4 in a larger ship).

◆ L 4

Dimensions: 533 mm × 3.13 m [21 × 123 in]
Weight: 525 kg [1157 lb]
Speed/Range: 30 kt/5000 m [5500 yd]
Warhead: 150 kg [331 lb] **Power Plant:** battery

This French lightweight antisubmarine torpedo is designed to attack submarines running at or below 20 kt. L 4 is used by aircraft and as the warhead of the Malafon missile. The torpedo uses active acoustic homing with an AS-4T seeker, at 32 kHz, with an average acquisition range of 1000 m [1094 yd]; L 4 has

L 4 BS

L 4 BS torpedo. (Direction des Constructions Navales)

a circular (helical) search pattern. This torpedo is produced by DTCN and entered service in 1964.

A modernized version can operate in shallow water, and another version is suitable for launching from surface torpedo tubes (3.3 m long, 570 kg [130 in, 1256 lb]).

◆ L 5/ L 7

Dimensions: 533 mm × 4.4 m [21 × 173 in]
Weight: 935 kg [2061 lb]
Speed/Range: 35 kt/7000 m [7700 yd]
Warhead: 150 kg [330 lb] **Power Plant:** silver-zinc battery

L 5 was a response to the major increase (approximately quadrupling) in sonar range associated with the new standoff weapons of the 1960s (such as ASROC, Malafon, and Ikara). The program began in 1960; compared to E 14, L 5 was expected to have twice the capability against both surface ships and submarines. In the same volume, L 5 achieves 10 more knots and greater range, partly by adopting a silver-zinc battery and a 2-rotor electric motor (of twice the power). This torpedo is also more difficult to countermeasure. L 5 was initially conceived as 2 torpedoes, 1 primarily ASW and 1, of greater range, primarily to attack surface ships.

Mod 1 is a ship-launched antisubmarine or antiship weapon. Mod 2 did not enter service. Mod 3 (5500 mm long [216.5 in], 1300 kg [2865 lb]) is submarine-launched against submarines; it was a direct replacement for E 12 and E 14. However, Mod 3 was deemed insufficiently effective against surface ships, and that led in turn to the wire-guided F 17. Mod 4 can be launched either by submarines or by surface ships, to attack fast submarines. It is a simplified version of Mod 1. Mod 4P is dual-purpose. The data above refer to Mod 4. Produced by DTCN, all versions are active-passive. Mod 4 has both acoustic and contact fuzes. Maximum operating depth is 500 m [1640 ft]. L 5 entered service in 1971.

L 7 is a major modification of L 5, a dual-purpose torpedo with a heavier warhead, for submarines. L 7 appeared about 1980.

◆ Z 13/Z 16

Dimensions: 550 × 7120 mm [21.7 × 280 in]
Weight: 1715 kg [3780 lb]
Speed/Range: 30 kt/10,000 m [10,900 yd]
Warhead: 300 kg [660 lb] **Power Plant:** battery

This submarine-launched pattern-runner was based on captured German technology (particularly that of the LUT torpedo). Z 13 has contact and magnetic fuzes. Running depth, set prior to launch, can be as deep as 18 m [59 ft], and the torpedo can be fired from depths as great as 180 m [590 ft]. Made by DTCN, Z 13 entered service in 1960; Z 16 is the export version of Z 13. These torpedoes are now obsolescent.

◆ Murène (NTL-90)

Dimensions: 324 mm × 2.6 m [12.75 × 102.4 in]
Weight: 250 kg [551 lb]
Speed/Range: 38 kt search, 53 kt attack; endurance over 10,000 yd at maximum speed (6 min at maximum speed, or 12 min at mixed speeds, gives approximately 10,000 yd at 53 kt and probably about 12,000 yd at mixed speeds)
Warhead: 50-kg shaped charge [110-lb]
Power Plant: aluminum-silver oxide battery (2-speed 136-HP engine-driving pump jet)

This lightweight torpedo was conceived as a replacement for the current Mk 46, for the L 5 shipboard self-defense weapon, and for L 4, the Malafon warhead. Homing is active/passive using multiple frequencies. Murène is expected to enter service

Murène. (Author)

in 1992. Early in 1988 the manufacturer, DCN, was claiming that this torpedo was 5 times as cost-effective as existing ASW torpedoes; presumably that statement refers to existing Mk 46s.

Information released thus far is that Murène is intended to attack targets at depths of 40–1000 m [approximately 130–1300 ft]; late in 1988 sea trials demonstrated that it could attack targets as shallow as 30 m [about 100 ft].

The torpedo sonar consists of a 30-transducer planar array, 2 side (left/right) arrays, and a depth finder (to avoid the bottom in shallow water). These sonars operate at 3 separate frequencies to overcome reverberation and countermeasures. The search pattern is rectilinear when Murène is launched from a ship and circular when it is dropped from an airplane or helicopter. The use of a straight-line search path and the statement that the torpedo can generally find a target during a single 360-deg pass suggest that it can look to the side (Mk 46, with only a nose transducer, albeit with a wide beam, must run in a snake pattern rather than a straight line). Presumably, then, the 2 side spot transducers are used to form a synthetic-aperture (side-looking) image, like a synthetic-aperture radar. However, 1 account suggests that the role of the flank transducers is to maintain contact while the torpedo comes abeam of the target.

Murène is said to be capable of tracking 12 targets (10, according to 1 account) simultaneously, the on-board computer predicting the target's course and estimating hit probability. This tracking is also used to distinguish decoys behaving unlike true targets, which is why the large track capacity is required.

Murène initially heads directly for the target, but then its

tracking element estimates target velocity and adopts proportional navigation. It is designed to hit at mid-beam (which DCN claims is a unique virtue). In trials, a Murène warhead striking at an angle of 50 deg to a simulated pressure hull cut through 20 mm of outer hull, 2 m of water ballast, and then 40 mm of pressure hull, and the torpedo would still have cut through another 300 mm of steel.

The combination of digital signal processing and target tracking requires considerable computer power. The homing-head signal processor is a Mangouste 50-MOPS computer, incorporating three 68000 processors, 2 buffer memory units, and 1 common memory. The central command unit (CCU), Capitole, incorporates four 68000 processors with a common memory. Total memory is 732k 16-bit words, and total throughput is over 60 MOPS.

The battery is silver oxide/aluminum with a potassium-hydroxide (caustic soda) electrolyte, stored in solid form and dissolved in seawater when the torpedo is running. A motor-driven pump delivers the electrolyte at a constant rate via a closed circuit that includes a heat exchanger and a gas extractor for the generated hydrogen. Such a system does not normally start instantly, but Murène required immediate power to drive it out of a steep dive when it was dropped in shallow water. The solution was to add 2 auxiliary batteries, 1 for the electrolyte pump and rudders, the other for the guidance unit. Thus the torpedo enters the water under full control. The propulsor is a pump jet with a 7-blade rotor; the fins are forward of the propulsor.

This torpedo began in 1976 as an Anglo-French project, but Britain withdrew in 1982 to develop Stingray independently. The French navy had bought U.S. Mk 46s in 1981 as interim weapons.

Murène light torpedo program's cost escalated 56% between 1982 and 1989 because of increased development costs. As of 1989, estimated unit cost was FFr 3.4 million [\$535,000]. However, in 1988 it was reported that total program cost (for 1000 torpedoes) would be FFr 10,000 million, or about \$1.7 billion (\$1.7 million each). The difference is presumably in the definition of unit cost.

In 1989 Chile became the first export customer, buying 20 Murènes for delivery beginning in 1992. In October 1990 the French announced that they wanted to merge Murène with the Italian A290 program. However, as of early 1991, this did not seem entirely likely. Reportedly, the French proposal was that the French-designed shaped-charge warhead be manufactured in Italy.

TORPEDO LAUNCHERS

◆ KD 59

Compressed-air catapult launcher for heavy torpedoes, typically in the superstructures of French destroyers. On board *Cassard*

Murène. Key: (1) stator (of pumpjet), (2) rudder actuator, (3) motor, (4) electrochemical unit (battery), (5) priming valve, (6) auxiliary batteries, (7) command central unit, (8) warhead (shaped charge), (9) motor-pump set, (10) acoustic head (signal processor), (11) degasser, (12) side array, (13) planar array, (14) control surfaces, (15) rotor (of pump jet). Seawater runs into the priming valve, is pumped through an electrolyte (caustic soda) and into an exchanger. A temperature-control valve adjusts the mixture of electrolyte and fresher water (from the exchanger) that enters the electrochemical unit. Electrolyte is pumped back out of the electrochemical unit, degassed, and then mixed with fresh seawater at the priming valve. (DCN)

there is a double set of KD 59E launch cradles carried athwartships, with a total of 10 L 5 Mod 4 torpedoes, and a device to transfer torpedoes from side to side.

◆ K69

New launcher optimized for the Murène torpedo, in single (KU69), double (KD69), and triple (KT69) versions, for launch at 0–30 kt. These launchers are compatible with the Mk 46 torpedo.

There is also a short 21.7-in torpedo tube on board the *Com-mandante Rivière*-class frigates, for L 3 torpedoes.

Daphne-, *Agosta*-, and *Le Redoutable*-class submarines have 21.7-in tubes; the nuclear attack submarines have 21-in tubes. The *Agosta* class can fire either 21- or 21.7-in torpedoes. These tubes employ pistons to expel torpedoes, a system introduced by the German navy during World War II. The piston is actuated by air, so this mechanism, like pure air ejection, suffers from depth limitations. Its advantage is that it is covert: no air bubble is released.

GERMANY (WEST)

Krupp-Atlas makes an AWD wake-detector for heavy torpedoes. It is not clear for which German-built torpedo(es) the wake-detector is built.

◆ DM1 Seeschlange

Dimensions: 533 × 4150 mm (4620 mm including wire reel) [21 × 163.4 {181.9} in] **Weight:** 1370 kg [3020 lb]
Speed/Range: 33 kt/6000 m; maximum range 12,000 m [6600/13,100 yd] **Warhead:** 100 kg [220 lb]
Power Plant: silver-zinc battery (contraprops)

This wire-guided (2-way link) ASW torpedo entered service in 1975 after tests in 1972–73. DM1 has much in common with Seal, but only about half the battery capacity, so that a 3D active sonar can be accommodated. Moreover, Seeschlange is much shorter than Seal and so can be accommodated in a small Type 206 submarine.

The initial design concept was a single universal homing head, suited to both active and passive homing, and realized in the later SUT (see below). Fuzing in both torpedoes is combined impact and proximity. Both Seeschlange and Seal have preset search programs to be used in the event the guidance wire breaks before the target is acquired, as well as re-attack logic (e.g., circular search in the event of target loss).

Wire guidance was adopted specifically to suit Baltic conditions, especially the shallow water and the very long detection ranges provided by modern radars and sonars. Torpedoes had to be fired at such great ranges that they could not be expected to home until well into their run; similar logic explains the wire-guided version of the U.S. Mk 37.

The name means Sea Serpent.

◆ DM2A1 Seal

Dimensions: 533 × 6550 mm (6080 mm in the original DM2) [21 × 257.9 {239.4} in] **Weight:** 1370 kg [3020 lb]
Speed/Range: 33 kt/20,000 m [22,000 yd]; also a lower-speed setting **Warhead:** 250 kg [551 lb]
Power Plant: silver-zinc battery (contraprops)

Seal is the antiship equivalent of Seeschlange, in service in 1969. Like Seeschlange, Seal is wire-guided, but it homes passively; and it has a larger warhead suited to antiship attack. The range is long so that the attacking platform can remain out of re-attack range, and the wire is a 2-way link. Fuzing is a combination of impact and proximity. When fired from surface platforms, these torpedoes are launched back over the stern, the tail pointing forward, the wire reeling out over the stern.

◆ DM2A3 Seehecht

Dimensions: 533 × 6600 mm [21 × 259.8 in]
Weight: 1370 kg [3020 lb]
Speed/Range: 35 kt/20,000 m [22,000 yd]
Warhead: 260 kg [573 lb] **Power Plant:** battery

Seehecht is a joint AEG/Elsag program to upgrade existing Seal/Seeschlange torpedoes. The seekers were upgraded first (DM2A3), then the propulsion (DM2A4). Selenia is responsible for the new homing head (as subcontractor to AEG). This torpedo entered service in 1987, initially for German Type 206A and Type 211 submarines and for the Norwegian *Ula* class. DM2A4 is scheduled to replace Seehecht in 1998.

◆ DM3

DM3 is the German designation for the U.S. Mk 37. The original armament of German submarines was Mk 37 for ASW and the British Mk 8** for antiship work. Mk 37 may have received a special German designation because of having been modified to German requirements.

◆ SST-3/SST-4 Seal

Dimensions: 533 × 6080 mm (6550 mm including wire reel) [21 × 239 {260} in] **Weight:** 1414 kg [3116 lb]
Speed/Range: 35 kt/24,000 yd; 23 kt/56,000 yd
Warhead: 260 kg [573 lb] **Power Plant:** battery

This antiship homing torpedo is fired by surface ships and submarines; SST-3 can be fired from a depth of 100 m [330 ft]. This torpedo entered service in 1972. The improved SST-4, with approximately the same characteristics, entered service in 1980. SST-4 was the torpedo carried (and fired) by the Argentine submarine *San Luis* in the Falklands. SST-4 differs from SST-3 in having 3 speeds (35 kt/12,000 yd; 28 kt/22,000 yd; 23 kt/40,000 yd). SST-4 can be fired by both submarines and surface craft.

This torpedo has probably been license-produced by IPTN of Indonesia since 1978. Users are Argentina (with the U.S. NT-37C), Greece, and Indonesia (probably superseded by SUT).

◆ SUT

Dimensions: 534 × 6390 mm [21 × 252 in]
Weight: 1414 kg [3116 lb]
Speed/Range: 34 kt/12,000 m; 23 kt/28,000 m [13,100/30,600 yd]
Warhead: 260 kg (claimed equivalent to 500-kg TNT) [573/1100 lb]
Power Plant: battery

This dual-purpose (surface and underwater target) wire-guided torpedo has active/passive terminal homing. SUT combines the features of the earlier Seeschlange and Seal. In 1978 AEG claimed that active acquisition range was 2000 m [2200 yd] and that passive acquisition range was 4000–6000 m [4400–6600 yd]. The seeker/control incorporates re-attack logic. Torpedo attitude is controlled by a free gyro acting directly on the control surfaces.

SUT was the result of a series of export developments. Seal (above) led to the export SST-4 antiship torpedo, which in turn inspired the dual-purpose SUT. SUT was announced in 1975, ran trials in 1976, and entered service in 1980. In 1986 Indonesia signed a contract for license production. An earlier dual-purpose torpedo, NIXE, was canceled in 1972 because of excessive cost. NIXE characteristics: dimensions 534 × 7200 mm [21 × 283.5 in], weight 1545/1800 kg with a 300-kg warhead [3405/3967 lb, 660-lb warhead], speed/range 50 kt/20,000 m [22,000 yd] with 8-cylinder Otto motor.

Users are Colombia, Chile, Ecuador, Greece, and Indonesia (for both submarines and surface ships). SUT is probably used by Argentina, India, Turkey, and Venezuela.

In 1978 it was reported that AEG was developing a light-weight SUT, as an alternative to Mk 46. This development never entered service.

◆ G7e

Dimensions: 53.3 cm × 7.0 m [21 × 275.6 in]
Weight: 3870 lb **Speed/Range:** 30 kt/8200 yd
Warhead: 617 lb **Power Plant:** battery

Norway reportedly still uses ex-German G7e torpedoes, modified for wire guidance, in coastal forts. This type of torpedo was manufactured by Whitehead as late as the early 1970s and may still remain in Italian war reserves. The Italian navy used

a wire-guided variant, carrying a Mk 44 homing torpedo, reportedly under the designation G6ef (Kangaroo), until A 184 entered service. In the designation, "G" indicates 21-in diameter and 7 is the length in meters; e indicates electric propulsion. The data above refer to one version of the wartime German weapon (TIIIa); the Norwegian torpedoes presumably have better batteries and motors.

TORPEDO LAUNCHERS

Virtually all German-designed submarines have swim-out torpedo tubes, a type selected by the main design organization, IKL, because it was more compact and also more efficient than any positive-ejection alternative. Compactness was particularly prized because of the tonnage limit imposed on the new German submarines. The standard MaK tube is 750 mm [29.5 in] or 775 mm [30.5 in] in diameter (the wider tubes are the 4 closest to the submarine's centerline). There are 4 sections: a narrow-diameter inboard tube (2.5 m long), a section (of the same diameter) penetrating the pressure hull (1.2 m long), a conical section (0.3 m long), and then a maximum-diameter outboard section (3.75 m long for 775 mm tubes, 3.5 m long for 7.5 mm tubes). These tubes are installed in a hull with a circular shape that greatly reduces flow into the tubes and, thus, makes swim-out much easier. The larger bow diameter is needed to provide sufficient flow as the torpedo accelerates out of the tube (less space is needed for the initial flow over the propellers). These tubes were made by Krupp-MaK; as of early 1988, the company had made 786 tubes since 1961.

Swim-out does impose some limitations. Since the torpedo leaves the tube at very low velocity, the launching submarine must move slowly and cannot maneuver freely while firing. Cavitation in the tube (because of the drag of water flowing between the tube wall and the torpedo) may reveal the submarine. Because the torpedo does not fill the tube, it may hang up (as reportedly occurred on board an Argentine submarine on trials during the Falklands War). A swim-out tube cannot be used for energetic internal-combustion torpedoes because their toxic exhausts will vent into the submarine. Finally, a swim-out tube cannot easily launch missiles (although for a time at least Whitehead was offering a compact electric motor to swim Harpoon capsules out of tubes).

The new German Type 212 submarines will have positive-discharge tubes designed as such. Krupp-MaK, the manufacturer of the new system, considered compressed air (rejected because it imposed depth limits), electric (too heavy), and hydraulic systems. One hydraulic type uses water pressure. One piston, which pushes the water out, is provided for each nest of 3 or 4 tubes, and one hydro-accumulator can be provided for each tube. This system launches torpedoes at a minimum speed of 12 m/sec at any depth, at a submarine speed of up to 12 kt. The firing interval, for a 6-torpedo salvo, is 5 sec. Alternatively, the system can fire 3 double shots at an interval of 10 sec. It takes less than 5 min to refill the accumulators. Work on this design began in 1983, and a prototype in a simulated submarine-section was under test until the end of June 1988. This is the type adopted for Type 212.

An alternative, which has apparently been adopted for the new Israeli *Dolphin*-class submarines, uses a hydraulically impelled thrust arm. This version achieves maximum launch speed (better than 10 m/sec) in about 1.5 sec and can run at a lower speed (0.2 m/sec) to launch mines. Development work began in 1986, and work on a prototype began in 1988. Because the thrust arm does not fill the tube, torpedoes can also swim out of it. Tube diameter is 710 mm [28 in], leaving a 90-mm [3.5-in] hydraulic cylinder at the bottom.

MaK supplied an air-expulsion system for existing swim-out tubes in Greek submarines, specifically to fire sub-Harpoon missiles. Tubes III, IV, VII, and VIII, which are already equipped to lay mines, are fitted. A caliber ring is mounted just inside the muzzle door to achieve a favorable pressure distribution during expulsion.

INDIA

◆ NST-58

In 1986 India announced that this torpedo, developed by the Naval Science and Technology Laboratory in Vishakhapatnam, was in production to replace the lightweight A-244/S in Indian service. No details were provided.

ITALY

◆ A-184

Dimensions: 533 mm × 6 m [21 × 236 in]

Weight: 1265 kg [2788 lb]

Speed/Range: 36 kt/10,000 m or 24 kt/25,000 m [11,000/27,300 yd]

Warhead: 250 kg [550 lb]

Power Plant: silver-zinc battery

The Whitehead-Motofides A-184 replaces "Kangaroo" (Cangaro), a shipborne antisubmarine torpedo consisting of an ex-German G6e, wire-guided, which in turn launched a Mk 44 homing torpedo upon approaching the submarine target. A-184 can be fired both from submarines and from surface ships.

A-184 is wire-guided, with digital active and passive terminal homing using 2 semicircular arrays, 1 in the vertical and 1 in the horizontal plane, for wide sector coverage. The torpedo employs contraprops and can be fired from both surface and submerged torpedo tubes.

The G6e/Kangaroo replacement requirement was issued in 1971, and the A-184 prototype tested in 1973. It entered service the following year. This torpedo has been exported to both Peru and Taiwan (GRC), the latter in 1986. Peru reportedly bought A-184 in preference to the German SST, the latter having failed in Baltic tests after the Falklands War. Reportedly, SST was unable to maintain its depth while under wire control.

Whitehead was the only pre-1943 Italian torpedo producer, and it is likely that some of the company's old straight-running 18- and 21-in torpedoes were exported postwar, e.g., for torpedo boats. It seems unlikely that any of these weapons have remained in service. Postwar, Whitehead either built or reconditioned German G6e electric torpedoes and developed Cangaro, which was the first postwar Italian torpedo. G6e was apparently the standard Italian submarine torpedo until A-184 replaced it.

The requirement for a G6e replacement was stated in 1971, and the A-184 prototype was tested in 1973; the torpedo entered service with the Italian navy, for both submarines and surface ships (the *Audace* and *Maestrale* classes), in 1974. Peru and Taiwan ordered A-184 in 1986. Whitehead has also discussed the purchase of A-184 with Chile, Indonesia, and Venezuela, with unannounced results. Of these countries, Indonesia decided to license-build German torpedoes, and Chile now manufactures Tigerfish. The Venezuelan Type 209 submarines are being refitted by their German builder, which would seem to imply that they will continue to carry German torpedoes.

A-184. (Whitehead)

◆ A-244 and A-244/S

Dimensions: 324 mm × 2.75 m [12.75 × 108.3 in]
Weight: 220 kg [235 kg for A-244/S] [485/518 lb]
Speed/Range: 30 kt/6000 m [6600 yd]
Warhead: 34 kg (blast) [75 lb]
Power Plant: lead-acid battery

A-244 was conceived as a replacement for Mk 44 Mod 2; this torpedo is sometimes described as an improved Mk 44-2. A-244 entered service in 1971, and the improved A-244/S in 1984. A-244 homes passively/actively using a single frequency. A-244/S homes actively/passively using triple-frequency pulses and a programmable seeker (search patterns and standard maneuvers). A-244/S's new CIACIO-S seeker may differ from that (Elsag AG70) of A-244 by using multiple preformed beams, the shape of which can be changed to suit acoustic conditions (spatially adaptive beam patterns). The pulses are coded FM slides. The manufacturer claims that its computer analyzes the structure, doppler, shape, and time-space coherence of returning echoes to reject clutter, multipath or mirror effects (from the surface or the bottom), and echoes from the bottom, and even to detect submarines (as opposed to natural formations) on the bottom. Mod 1 is for helicopter launch, Mod 2 for aircraft.

The A-244 requirement was issued in 1968; research was completed in 1973; and production began in 1975.

Work on CIACIO began in 1964 after Selenia gained experience with the Mk 44 seeker during license production. The company described the seeker as using principles not previously used in underwater detection and called the seeker compatible with future light- and heavy-weight torpedoes. A 60-kHz CIACIO 60 was completed in 1966, using the transducer of the Mk 44 (but with new operating principles). CIACIO 30, operating at 30 kHz, was completed in 1968; and it led to CIACIO-S, which appeared in 1972. CIACIO-S was tested in the laboratory in 1973, with static sea trials following in 1974 and live trials (using Mk 44 torpedoes) in 1975. Very shallow water trials were carried out in 1977-78.

A-244/S Mod 1 was ready for delivery in 1987. Export customers are Argentina, Ecuador, Greece, India, Indonesia, Iran, Iraq, Libya, Nigeria, Pakistan, Peru, Singapore, Taiwan, Turkey, and Venezuela. Estimated unit cost is 70% that of a Mk 46, i.e., about \$140,000; A-244/S probably costs \$145,000.

Before developing A-244, Whitehead developed A-243 (presumably a replacement for Mk 43), which did not enter production. The company also made about a hundred Mk 44s under license.

A-244/S at Farnborough, 1990. The shroud ring (used instead of fins for directional control) suggests its relationship with the earlier U.S. Mk 44. The object in the foreground is a dummy Mk 11 depth charge; in the background is a Stingray torpedo. (Author)

◆ A-290

Dimensions: 324 mm × 2.75 m [12.75 in × 108.3 in]
Speed/Range: 50 kt/ca 10 km [10,900 yd] (speed also reported as 40-45 kt)
Warhead: shaped charge
Power Plant: aluminum-silver oxide battery

A B515 triple tube launches an A-244S Mod 1 torpedo. (Whitehead)

A-290. Note the pump jet. (Whitehead)

The A-244 replacement, A-290 is to enter service in the 1990s. This torpedo will incorporate some A-244 technology including the CIACIO-S seeker; subsystem tests began in 1987. Development began in 1981. Improvements will include greater power (for a speed of 40-45 kt), a pump jet, improved tracking range, better passive capability, and a greater ability to classify shallow targets in warm water. The manufacturer, Whitehead, states that the design emphasizes improved signal processing (for greater acquisition range) rather than greater speed.

In 1988 the major question in the A-290 program is reportedly which of several alternative computers to use. The A-290 torpedo was displayed publicly for the first time at the Mostra Navale exhibition at Genoa in May 1989. It is to enter service in the Italian navy early in 1992.

◆ LCAW (A200)

Whitehead's Low-Cost Antisubmarine Weapon is a very simple torpedo intended mainly to help classify targets. At present, the only safe way to deal with a possible target is to drop a homing torpedo on it, either to kill it or at the least to make it run (and thus to confirm that it is a real target). That was the role of the depth charges of the past, but they are no longer viable, and homing torpedoes are considered much too expensive to be used as classifiers. Dimensions: 123 mm × 1 m (15 kg, 4-kg shaped-charge warhead). Performance: 18 kt for 3 min (range 2+ km). LCAW has an active seeker.

TORPEDO LAUNCHERS

◆ B.512

Whitehead submarine torpedo tube.

◆ B.515/ILAS-3/SPS 104

ILAS 3, the standard Italian lightweight-torpedo launching system, consists of a Whitehead SPS 104 FCS system (for torpedo

presetting and launch control) and 2 sets of B.515 triple tubes. In its most elaborate form, SPS 104 incorporates a computer. It displays the tactical picture and torpedo presets and automatically transmits the order to fire; it can be integrated into a larger FCS. SPS 104 exists in 3 versions: (i) manually controlled via a remote-control panel in CIC; (ii) controlled directly by the CDS; and (iii) connected directly with the sonar (for a ship without a CIC), computing target course and speed and choosing optimum presets. The panel selects the tube and presets and fires the torpedo. Firing is by compressed air, and the tubes have heaters. Whitehead also makes a lightweight FCS in 2 versions: (i) for helicopters with dipping sonars, and (ii) for maritime-patrol aircraft and helicopters without dipping sonars.

◆ B.516

Whitehead heavy torpedo tube for surface ships, typically firing aft over the stern (for wire guidance). There is also a B.516/A version.

JAPAN

Japan currently uses Mk 44 and Mk 46 lightweight torpedoes and Type 80 heavy torpedoes.

◆ Type 80

Type 80 is a wire-guided ASW torpedo comparable in size to the U.S.-supplied Mk 37, but with better performance; speed is over 30 kt. Type 80 is about the same size (19-in diameter and short length) as Mk 37. Type 80 was developed from the GRX-1 experimental torpedo, but it also drew on data from the ongoing GRX-2 program. Research began in JFY65, the designation Type 80 being applied in JFY80. Production began in JFY84. At that time the equipment designator G-11 was applied.

This torpedo is carried by the *Uzushio* and *Ushio* classes. Type 80 replaced the Japanese version of Mk 37, Mk 37-0-N.

◆ Type 89

This new standard heavy (submarine) thermal torpedo is roughly equivalent to the U.S. Mk 48. Reported maximum speed is 70 kt, with a range of 30,000 m [32,800 yd]. It was developed in parallel with the electric (silver-zinc) GRX-1. Development was protracted; as of 1983 GRX-2 was to have been ready for designation (standardization) in JFY85, but that occurred only in JFY89. Despite the delay, Japan did not seek license production of either Mk 48 or Mk 48 ADCAP.

The current R&D program includes work on counter-countermeasures improvements for this weapon.

◆ GRX Series

These are experimental torpedoes. When a torpedo is adopted for service, its GRX designation is replaced by a Type number indicating the JFY in which it is applied. GRX-2 became Type 89 in 1989. The current research program includes a new torpedo launching system.

GRX-4 is a new lightweight torpedo broadly comparable to the U.S. Mk 50, with a shaped-charge warhead, a SCEPS power plant, and a propulsor. A development contract for this torpedo was awarded to Mitsubishi Heavy Industries in March 1987. GRX-4 is apparently being developed as an alternative to a Japanese production program for Mk 50. Its shaped-charge warhead

was tested successfully against a double-hull submarine section in July 1989; apparently the guidance system is designed to ensure that the torpedo hits at right angles to its target.

GRX-4 supersedes GRX-3, an earlier, experimental, air-launched, electric, lightweight torpedo developed as an alternative to Mk 46. Begun in 1975, GRX-3 was abandoned as too large and too heavy.

The 2 current developmental torpedo programs are GRX-5 and -6.

TORPEDO LAUNCHERS

The standard submarine tube in the *Uzushio* class is HU-602; it was succeeded by HU-603 in the *Yushio* class and by HU-603B in the new *Harushio* class. From the 5th *Yushio* (*Nadashio*), the HU-603 tubes are fitted to fire Harpoon missiles as well as torpedoes (the earlier units were later modified). HU-603 can also launch torpedoes at greater depths than can its predecessor.

The Japanese version of the U.S. Mk 32 triple tube is designated Type 68.

SWEDEN

◆ Type 42 Series

Dimensions: 400 × 2440 mm [2620 mm with wire dispenser] [15.75 × 96.1/103 in] **Weight:** 250/298 kg [550/657 lb]

Speed/Range: 25 kt/20,000 m (10,000 m at high speed) [22,000/10,900 yd] **Warhead:** about 50 kg [110 lb]

Power Plant: battery (2-speed motor)

Type 42 is a lightweight electric ASW torpedo (with secondary antiship capability) that can be launched by submarines, surface ships, and helicopters. It was originally designed for direct homing (using a passive sonar scanning both in depth and in azimuth), but it is adapted for wire guidance. In this form Type 42 is unique among modern lightweight weapons in being wire-guided; that guidance is necessary to assure homing under difficult acoustic conditions (e.g., in shallow water). Type 42 has both impact and proximity fuzes.

Type 42 entered production about 1976, succeeding Type 41, which had similar dimensions and performance (400 × 2440 mm, 250 kg, 25 kt/20,000 m [22,000 yd]). Presumably, Type 42 introduced the 2-speed motor, for a higher-speed attack.

Current versions are the following:

Type 422 (298 kg, ranges as above), 1983. Compared to the original Type 42, this version has a better wire data link and a better signal processor.

Type 423 (290 kg [639 lb], 400 × 2850 mm [15.75 × 112 in]).

Type 427 is the current export version of 422/423 (400 × 2600 mm [15.75 × 102 in], 298 kg, silver-zinc battery). Total weight is also given as 310 kg [683 lb], length as 2.85 m [112 in]. This version has been in service since 1982. It incorporates some Type 617 technology.

There is a special "incident" version of Type 42 with a less lethal warhead, to force a submarine in Swedish waters to surface. This development parallels that of Elma and Malin (see unguided weapons below).

Type 43 is descended from Type 41, a homing (dual-purpose) weapon introduced about 1960. Type 41 was developed into Type 411, for the *Abborren*-class submarines (now discarded), which were then being rebuilt for ASW, and then into Type 412, for the *Sjoormen* class. A projected Type 413 was not pur-

(Below) Type 43 torpedo. (FFV)

sued. Instead, a new series was begun with Type 42. Type 421 was a specialized ASW torpedo carried by the *Nacken* class, and the wire-guided Type 422 was carried by helicopters. The abortive Type 423 was intended specifically for the *Vastergotland* class. The next series, Type 43 (described below), introduced data programming at transmission, an autopilot, and a 3-speed motor. Type 431 is designed for use by both the *Vastergotland* class and the corvettes. Type 43X0 is the export version. A new lightweight torpedo is expected about 1990. It should have improved performance and better counter-countermeasures features, within smaller dimensions.

FFV claims that a lightweight torpedo suffices for ASW because the tamping effect of the water surrounding a submarine will amplify the effects of its 30–70-kg warhead. FFV considers at least a dual-speed motor necessary because the same torpedo may have to deal with moderate-speed (diesel) and high-speed (nuclear) targets. The company considers wire guidance, for 3D maneuvers, essential, even though other lightweight ASW torpedoes are entirely self-guided.

◆ Type 43X0/Type 431/Type 432

Dimensions: 400 × 2850 mm [15.9 × 112 in]
Weight: 350 kg (280 kg in helicopter version) [771 {617} lb]
Speed/Range: range 32,000 yd
Power Plant: silver-zinc battery; 3-speed motor

Type 431 is an improved Type 427 optimized to attack very quiet submarines in shallow water. Development was ordered early in 1984. The new digital computer, which is programmed in Pascal, is smaller than its predecessors, and the guidance wire carries more information. Signals sent to the torpedo control speed, depth, and course and provide target data. The torpedo reports its position, speed, course, depth, homing system parameters, and target radiated noise. The on-board computer calculates expected target position and can independently initiate 1 of several search patterns if the guidance wire breaks. Speed options are 15, 25, and 35 kt, the last faster than the high-speed option of Type 42.

Type 43 differs from Type 42 in being of modular construction, to accommodate a special warhead or battery. The basic air-launched version is Type 432, which has a lighter battery than the ship-launched version (Type 431); capacity is 4.2 rather than 5.6 kW-hr. In both cases, the battery is more durable than that of Type 42, capable of 30 rather than 10 exercise firings between overhauls. Type 43X0 is an export version, which can be delivered with a different battery.

The first Swedish navy order for Type 431 was announced early in 1986. This torpedo entered service in 1987.

The Swedish navy recently (1990) ordered Whitehead A-244/S torpedoes to gain experience with active seekers. It was very impressed by the torpedo's ability to detect and attack a bottomed submarine in difficult underwater terrain, i.e., on the bottom next to a steep rise. The Type 43 series successor, now designated Type 45, will probably have an active/passive seeker.

At Defendory in October 1990 FFV announced the first order for Type 45, from the Swedish Defense Materiel Administration. Type 45 will have the Type 43 hull with a new seeker and a better signal processor. The first Type 45s are to be delivered in 1993.

◆ Type 61

Dimensions: 533.4 × 7025 mm [21 × 288 in]
Weight: 1765 kg [3890 lb]
Speed/Range: 45 kt/20,000 m [22,000 yd] (some sources claim maximum speed is over 60 kt)
Warhead: 250 kg [551 lb]
Power Plant: hydrogen peroxide/alcohol (350-kW 12-cylinder engine)

This long-range wire-guided antiship torpedo is fired from both submarines and surface ships. The manufacturer, FFV, claims that the HTP propulsion system provides 2 or 3 times the range of conventional thermal or electric torpedoes. This torpedo is also wakeless. Course and speed are maintained within 0.3% during the run to the target. Wire guidance is necessary to exploit the very long range of the torpedo; Sweden was 1 of the first countries to employ submarine-launched wire-guided torpedoes operationally.

Later versions (613/617), capable of longer ranges, have terminal acoustic homing (wake homing in at least some cases). Two alternative fuzes (inertial or acoustic proximity) are available.

Type 61, whose data are listed above, entered service in 1968. The prototype was Type 611; Type 612 was the first production version (dimensions 533 × 7500 mm [21 × 295 in]).

Type 613 is the current Swedish navy service version (533 × 7025 mm, 1765 kg [21 × 277 in, 3890 lb]). It incorporates a digital computer that can be programmed to suit particular environmental and threat conditions. This version increased range from 20,000 to 30,000 m [22,000 to 32,800 yd], partly as a result of adopting a 2-speed motor, the additional range being exploited by the introduction of terminal homing and, therefore, 2-way wire guidance. Production began in 1983, with first deliveries following in 1984.

Announced in 1982, Type 617 is the export version of 613. 617 entered service in 1984. Length is 6890 mm [271 in]; weight is 1860 kg [4099 lb]; and estimated performance is 60 kt/30,000 m [33,000 yd]. The warhead weighs 240 kg [529 lb].

This torpedo has been exported to Denmark and Norway.

Swedish work on heavy HTP torpedoes began about 1955, with the surface-launched Type 14, from which were derived a straight-running Type 141 and a wire-guided Type 142. About 1960 a corresponding submarine torpedo, Type 27, was introduced. From it were derived Types 271 and 272, the latter entering service about 1964. About 1970 a single torpedo, Type 61, for both surface and submarine launch, was produced. Type 611, a wire-guided HTP weapon, was derived directly from Type 272. From 611 evolved Type 612 (swim-out launch; about 1975); from Type 612 were derived the noisy, fast Type 618 (about 1980) and then the homing Type 613, with data transmission along its guidance wire and with a 2-speed motor. Type 617 is the export version of Type 613.

Type 61 is unique among modern Western wire-guided torpedoes in being suitable for forward firing from surface ships (the German torpedoes, A-184, and the abortive surface-launched version of the U.S. Mk 48 all had to be fired aft, over the stern). Presumably, Type 61 accelerates fast enough to carry its wire clear of the firing ship.

◆ 2000 'S'

FFV announced this next-generation, dual-purpose, wire-guided, export torpedo, now under development, in 1990. Endurance may be over 1 hr at a maximum speed of 60+ kt. The new semiclosed-cycle, HTP, swashplate power plant drives a pump

(Below) Type 617 torpedo. (FFV)

jet propulsor. The new AT-96 seeker can be used either passively or actively, and there may also be a wake-following mode.

◆ Angler

Angler was a Swedish program for a hand-launched torpedo or intelligent depth charge, to be used primarily against intruding mini-submarines. Announced in 1987, Angler was intended to fill a gap between conventional torpedoes and the Elma depth charge. Two U.S. companies, Lockheed (the Lockheed Lightweight Torpedo) and General Dynamics (the Self-Propelled Depth Charge), competed. See the U.S. section for more details of the Lockheed weapon. The Swedish navy reported that it had a design speed of 6–7 kt (demonstrated speed was 2–3 kt). It used a fiber-optic link to relay its sonar and color television pictures. The General Dynamics weapon used a different technology (no details are available). Although the Royal Swedish Navy was impressed with the fiber-optic link, it found the Lightweight Torpedo too slow, and the program was canceled in favor of the alternative versions of Elma described below. The Lockheed weapon was also considered for mine countermeasures. Both the Lockheed and the General Dynamics weapons were private ventures, although the U.S. Navy was kept aware of program progress. Work probably began about 1985 under the auspices of the Swedish National Defense Research Institute.

During the mid-1980s there was at least 1 project to develop an intelligent depth bomb for the standard Bofors 375-mm mortar. It may have helped inspire the current NATO low-cost ASW weapons program.

USSR

Data below are necessarily incomplete. Information on torpedoes deployed since about 1958 is unofficial, from a few recent publications. Material on earlier Soviet torpedoes is taken from a mix of Soviet official sources and declassified Western intelligence data.

For thermal (e.g., steam) torpedoes, the standard designation indicates the caliber and the year of origin, e.g., 53-39 is 53-cm caliber and originated in 1939. Designations of electrical torpedoes vary; the earliest was ET-80. More recent types appear to follow thermal torpedo practice, with the prefix E. There are also other special designations (see below).

Most of the information on the most recent Soviet torpedoes listed here comes from a 1987 publication, but the reader is

The Soviet Union was unique in developing a series of torpedoes specially adapted to be dropped from high altitude and long range. One example, this rocket-propelled torpedo has a special nose break to reduce the impact of hitting the water. Although the torpedo has a tail shroud, it has no propeller. This torpedo is the conceptual ancestor of the long-range antiship missiles of the AS series. Although this photograph is dated 1971, it was probably taken in the late 1950s; the airplane is an IL-28T. This weapon was designated RAT-52. It was also used by the PRC. (TASS from SOVFOTO)

Quintuple torpedo tubes, on board the cruiser *Kerch*, 1989. The loading trolley is under the muzzles of the tubes. (Eric Grove)

Twin torpedo tubes on board the *Sovremennyy*-class destroyer *Bezuprechnyy*, 1990, showing presetting ports. (Eric Grove)

cautioned that none of the torpedoes there described came into service later than 1981.

The very brief notes are taken from material released by the U.S. Navy in 1990. The reader is cautioned that the designations given below are a mixture of actual Soviet designations and *Soviet-like* designations applied by Western navies (torpedo caliber and IOC date).

The 1987 article did not list surface-ship torpedoes. Most Soviet surface combatants, from light frigates up, carry 53-cm antisubmarine and antisurface torpedoes. There is now a 53-cm wire-guided ASW torpedo: the evidence is that Grisha-V-class corvettes, which entered service from 1985 on, have had their torpedo tubes lengthened to allow for the wire dispenser.

Reportedly, some portions of the Mk 48 torpedo design were compromised to the Soviets in the late 1970s. It seems likely, then, that the Soviets now have reasonably quiet thermal piston engines for homing torpedoes equivalent in speed and endurance (but probably not in acoustic performance) to Mk 48 and to Mk 46.

◆ Type 65

Dimensions: 650 × 9140 mm [25.6 × 359.8 in]
Speed/Range: 50 kt/54,000 yd; 30 kt/109,000 yd [50,000 and 100,000 m, respectively]
Warhead: 900 kg approx [1980 lb]

This torpedo, which is probably an enlarged 53-65, became operational in 1981; the Soviet designation is, therefore, probably something like 65-80. Type 65 has attracted very considerable attention in the West because it has the sort of warhead required to sink a carrier and because wake homing is virtually impossible to counter by means of a towed or thrown decoy. Presumably, the torpedo is fired on a gyro course toward the expected target position, the wake-homing feature considerably enlarging the effective target length and thus making very long firing ranges (as indicated above) useful. In this sense Type 65 might be regarded as an underwater cruise missile, supplementing antiship cruise missiles flying through the air.

This torpedo marks a drastic change in Soviet torpedo size and, therefore, can be fired only by recent submarines. It seems likely that Type 65 was designed because 65-cm tubes had already been selected for Victor-II and later submarines, to fire the SS-N-16 ASW cruise missile. The SS-N-21 also seems to use this tube.

Victor-III-class submarines are fitted with four 65-cm and two 53-cm torpedo tubes, the 2 smaller-diameter tubes mounted over the 4 larger ones. The continued use of smaller-diameter tubes suggests that some special 53-cm weapon, which cannot be fired from the larger tube (i.e., using a liner), is carried. The most likely candidate would be a nuclear torpedo that would be carried more or less permanently in the tube for security reasons. That possibility in turn would refute reports that the 65-cm torpedo has a nuclear warhead. Alternatively, the smaller-caliber tubes might be reserved for wire-guided ET-80A (1980) ASW torpedoes, for close-in defense, or for large-caliber decoys.

A nuclear version of the 65-cm torpedo has been reported. From Victor-II onward, most Soviet submarines have tubes with 65-cm diameters, so it would be reasonable to imagine that the Soviets have produced 65-cm weapons in all 3 major torpedo categories: antiship (as here), nuclear, and electric antisubmarine. To limit the arsenal to existing smaller-caliber weapons (fired, presumably, using unwieldy tube liners) would be to disregard the considerably greater volume (e.g., for endurance, guidance, or both) offered by the larger torpedo caliber.

◆ 53-27L

Dimensions: 21 in × 23 ft **Weight:** 3800 lb
Speed/Range: 43.5 kt/4570 yd **Warhead:** 550–600 lb
Power Plant: air-steam

This torpedo was carried postwar by North Korean motor torpedo boats, and it may have been exported to other Soviet client states. The L may have indicated manufacture at Leningrad. Running depth was 16–40 ft.

◆ 53-38/53-38U

	53-38	53-38U
Dimensions:	533 × 7200 mm [21 × 284 in]	533 × 7450 mm [21 × 293 in]
Weight:	1615 kg [3560 lb]	1725 kg [3800 lb]
Speed/Range:	44.5 kt/4000 m; 34.5 kt/8000 m; 30.5 kt/10,000 m [4400; 8700; 10,900 yd]	
Warhead:	300 kg [661 lb]	400 kg [882 lb]
Power Plant:	HPT, 2-cylinder horizontal engine	

These 2 were the standard surface and submarine torpedoes in service at the outbreak of World War II; 53-38U was a rein-

forced version of the basic weapon. There were several major wartime modifications. A proximity fuze (NVS) entered operational service about 1943. Running depth was 16–40 ft.

◆ 53-39

Dimensions: 533 × 7488 mm [21 × 294.8 in]
Weight: 1780 kg [3923 lb]
Speed/Range: 51 kt/4000 m; 39 kt/8000 m; 34 kt/10,000 m [4400/8700/10,700 yd]
Warhead: 317 kg [699 lb]
Power Plant: HPT, 2-cylinder horizontal engine

An improved 53-cm [21-in] torpedo, 53-39 entered service in July 1941. 53-39 had a more powerful engine and greater air, kerosene, and oil capacity. This weapon introduced a new MO-3 gyroscope permitting angled fire (from 0–90 deg port or starboard).

◆ 53-51

Dimensions: 533 × 7800 mm [21 × 307 in]
Speed/Range: 51 kt/4000 yd; 39 kt/10,000 yd
Warhead: 400 kg [882 lb]

53-51 was the postwar Soviet submarine torpedo, a straight or pattern runner. Maximum launch depth was 106 m [348 ft]; maximum operating depth was 14 m [46 ft]. The exploder was impact or magnetic (proximity).

◆ 53-56

Dimensions: 533 × 7740 mm [21 × 305 in]
Speed/Range: 51 kt/9000 m; 39 kt/18,500 m [9800/20,200 yd]
Warhead: 400 kg [882 lb] **Power Plant:** HTP/fuel (open cycle)

53-56, the first operational Soviet torpedo with an unconventional engine, was a modified 53-51.

◆ 53-56V and 53-56VA

Weight: 1900 kg [4188 lb]
Speed/Range: 51 kt/4000 m, 41 kt/8000 m
Warhead: 400 kg **Power Plant:** air-stream (piston)

These are standard Soviet export torpedoes. 53-56VA is a torpedo-boat weapon, reportedly 276 in long, weighing 3960 lb, and with a speed/range of 28–30 kt/6000 yd. Both torpedoes have pattern-running modes based on the wartime German FAT. Data on 53-56V come from a 1986 Soviet book on torpedoes. In the book, 53-56V is described as a well-known type, along with 45-36N and 53-39PM (pattern-running). Presumably, all have been exported.

◆ 53-?

Dimensions: 533 × 7200 mm [21 × 283.5 in]
Speed/Range: 50 kt/11,000 m; 32 kt/21,000 m [12,000/23,000 yd]
Warhead: nuclear, approx 15 kT
Power Plant: HTP/fuel (open cycle)

The nuclear version of the 53-56 carries a 15-kT warhead. This torpedo became operational in 1959 or 1960, so the designation is presumably 53-59 or 53-60. This torpedo was almost certainly the weapon element of the November-class SSN weapons system, the submarine being fast enough to reach a firing position off the bow of the fast target (e.g., an aircraft carrier). The torpedo did not home; it exploded at a set range as indicated by the propeller turn count. The propeller count was also used to arm the warhead after the torpedo passed a set enabling range. There was an anticircular turn mechanism to protect the firing submarine.

At one time it was suggested that this torpedo was also the first Soviet naval strategic nuclear weapon because it could be delivered to enemy harbors.

There is some evidence that Soviet nuclear torpedo warheads were unsafe. In February 1972 a Soviet submarine off the North American coast suffered crew casualties because of radiation leakage from torpedo warheads. The 2 nuclear torpedoes on board the Whiskey-class submarine that grounded in Sweden in 1981 had noticeable radiation signatures.

◆ E53-66

Electric gyro (straight- and pattern-runner) torpedo for submarine and surface launch.

◆ E53-75 and -79

Electric torpedoes for air and missile delivery. It is not clear to what extent these 53-cm torpedoes replace (or are replaced by) E53-79.

◆ E53-70

Submarine- and surface-launched thermal pattern-runner.

◆ E53-83

Follow-on to E53-68: submarine- and surface-launched thermal antiship torpedo (wake-follower). This weapon presumably incorporates the Mk 48 propulsion technology compromised in the 1970s.

◆ E53-?

This submarine-launched electric dual-purpose torpedo entered service in 1983. It is officially listed as a 53-series rather than an E53.

◆ ET-80A/SAET-50/SAET-60

Dimensions: 21 × 307 in **Speed/Range:** 23.3 kt/8000 yd

Warhead: 600 lb TNT

Power Plant: 46-cell lead-acid battery; 56-HP motor with contra-props

ET-80A was the first Soviet homing ASW torpedo, a modified version of the earlier ET-80. ET-80A was fired only by submarines.

ET-80A could acquire a cavitating submarine (21 dB at 24.8 kHz) at about 700 yd. The torpedo could be set to run as deep as 325 ft, although it could dive to 500 ft when homing and could attack a target either above or below its set depth. The exploder was a modified version of the wartime German TZ-5 with 2 additional horizontal receiving coils, with a range of 100 ft (above, below, or alongside).

ET-80A first appeared about 1961. As of 1962, the U.S. evaluation was that it was an interim weapon pending the use of the same passive-homing device in a smaller and more modern torpedo with greater maneuverability. That torpedo was presumably the earliest version of the 40-cm torpedo described below. A passive homer of this type could be used against surface ships as well as against noisy submarines.

As applied to this weapon, ET-80A was an ONI, not a Soviet, designation.

The Soviets have published details of SAET-50, which they describe as their earliest homing torpedo and which may correspond to ET-80A. Dimensions are 530 × 7454 mm [20.9 × 293.5 in]; weight is over 1600 kg [over 3520 lb]; warhead is 375 kg [827 lb]; and performance exceeds 40 km/hr over 7000 m [21.6 kt/7650 yd]. A 1986 Soviet book states that SAET-50 can be set for circular or sector search. In the latter mode, the torpedo turns to 1 side for a period of several seconds. If no target is detected, the torpedo swings back onto its initial straight course. There is no indication of a helical search mode. The torpedo sonar consists of 4 nickel-plate (magnetostrictive) transducers operating at 25 kHz and forming a line across the nose of the torpedo.

SAET-60, which entered service in 1965–66, has been described as the first Soviet antiship homing torpedo. Its dimensions match those of the ET-80A listed above: 533 × 7800 mm. However, performance is higher: 35 kt/15,000 m [16,400 yd]. The warhead is 400 kg [882 lb]. The power plant is a silver-zinc battery. Operation is passive at 25 kHz. The exploder is impact or acoustic proximity.

◆ ET-80(66)

Dimensions: 533 × 7700 mm [21 × 303 in]

Speed/Range: 35 kt/10,000 m; 20 kt/40,000 m [11,000/43,700 yd]

Warhead: nuclear: 20 kT

Power Plant: silver-zinc batteries

A quieter (but slower) nuclear antiship torpedo, ET-80(66) replaced the nuclear version of E53-56. Maximum running depth was 305 m. A deep run would tend to increase the area affected by the nuclear burst, thus reducing the effect of any aiming error by the submarine.

◆ SET-65

Dimensions: 533 × 7800 mm [21 × 307 in]

Speed/Range: 35 kt/10,000 m; 24 kt/20,000 m [11,000/22,000 yd]

Warhead: 272 kg [600 lb]

Power Plant: battery

SET-65 is a submarine-launched torpedo, operating down to 400 m. It became operational in 1967.

◆ E53-65

Dimensions: 533 × 7800 mm [21 × 307 in]

Speed/Range: 55 kt/14,000 m; 40 kt/24,000 m [15,300/26,200 yd]

Warhead: 400 kg [882 lb]

Power Plant: HTP/fuel using new multipiston engine

This torpedo reportedly introduced both a new power plant (probably semi-closed-cycle, reusing exhaust gas) and wake-homing into Soviet practice. E53-65 was the first Soviet thermal torpedo capable of homing, and it became operational in 1968.

◆ E53-68

Dimensions: 533 × 7200 mm [21 × 284 in]

Speed/Range: 45 kt/15,000 yd **Warhead:** nuclear: 20 kT

Power Plant: HTP/fuel closed-cycle (wakeless)

This torpedo, a modernized nuclear version of E53-65, became operational in 1970. E53-68 can be launched from as deep as 106 m [348 ft], and it can run down to 300 m [984 ft]. As in the earlier thermal nuclear torpedo, E53-68 is a straight-runner using propeller turn count to measure the distance to a preset detonation.

◆ E53-VA

The standard Soviet export antiship torpedo, E53-VA reportedly had a 562-kg [1240-lb] warhead and a magnetic influence fuze.

◆ ET-80A

Dimensions: 533 × 7800 mm [21 × 307 in]

Speed/Range: 35 kt/15,000 m; higher speed for 12,000-m range [16,400/13,100 yd] **Warhead:** 272 kg [600 lb]

Power Plant: battery

The ET-80A designation has already been used; this torpedo presumably has some other designation, as yet unpublished. This torpedo was probably a modernized SET-65; it was the first Soviet wire-guided torpedo. It also had an improved power plant. Submarine-launched, ET-80A can operate down to 400 m.

This torpedo became operational in 1977.

A wire-guided torpedo with similar performance is probably in limited production.

◆ E45-70A

Dimensions: 450 × 3900 mm [17.7 in × 153.5 in]

Speed/Range: 28–30 kt/10,000 m [11,000 yd]

Warhead: 90 kg [198 lb]

E45-70A is the payload of the SS-N-14 missile. This torpedo executes an up-and-down helical search, down to 305 m [1000 ft].

◆ E45-75A

Dimensions: 450 × 3900 mm [17.7 × 153.5 in]

Speed/Range: 38 kt/9000 yd **Warhead:** 90 kg [198 lb]

E45-75A is a missile- (SS-N-14 and -16) and aircraft-delivered weapon, an updated E45-70. -75A became operational in 1973. Maximum operating depth is about 300 m.

◆ E45-75A Mod

Dimensions: 450 × 4600 mm [17.7 × 181.1 in]
Weight: approx 840 kg [1851 lb]
Speed/Range: 38 kt/8000 m [8700 yd]
Warhead: 90 kg [198 lb]

A lengthened, modernized E45-75A, Mod is reportedly used as the payload of SS-N-14 and -16.

The 1990 U.S. release mentioned only 2 E45-series torpedoes, IOC's 1965 and 1973. Both were electric active-acoustic homers for air delivery.

◆ SET-40

Dimensions: 400 × 4500 mm [15.9 × 177 in]
Speed/Range: 28 kt/10,000 m [11,000 yd]
Warhead: 100 kg [220 lb] **Power Plant:** silver-zinc batteries

SET-40 was the first Soviet lightweight torpedo, for firing from small surface ships (light frigates and corvettes). It may also have been delivered by aircraft, though that delivery seems unlikely in view of the development of the 45-cm series. Maximum acquisition range was 585 m [640 yd: from the seeker ping rate], and maximum operating depth was about 300 m [984 ft]. This weapon used an active acoustic proximity fuze (frequency reportedly 650 kHz) similar to that of the contemporary French L 3.

This torpedo caliber first appeared in the Soviet fleet in the early 1960s on board Petya- and Mirka-class corvettes.

The 1990 U.S. release mentions E40-?, an electric dual-purpose straight-runner or acoustic homer for use by submarines and surface ships. This may be SET-40 or E40-75A.

◆ E40-75A

Dimensions: 400 × 4500 mm [15.9 × 177 in]
Speed/Range: 30 kt/14,000 yd **Warhead:** 100 kg
Power Plant: battery

The 400-mm torpedo is not nearly as ubiquitous in Soviet service as is the lightweight (324-mm) torpedo in the West. This torpedo is carried only by small corvettes (Poti and Pauk classes) and by the older light frigates (Mirka and Petya). The newer light frigates (Grisha and Parchim classes) carry 53-cm weapons. That allocation may imply that the 40-cm torpedo has never been altogether satisfactory.

◆ 40-?

Dimensions: 40 cm × 3.5 m [16 × 138 in]
Weight: 850–950 kg [1873–2093 lb]
Speed/Range: 35–40 kt/7 nm (endurance 10–12 min)
Power Plant: seawater battery

This torpedo, developed in the mid-1970s, was described by a Soviet émigré. It was intended as the SS-N-16 payload (Project Vodopod) and also as an SS-N-14 payload (Project Veter) and as an air-dropped torpedo, for bombers (presumably Bear Fs, as Project Orlan). The impetus seems to have been Project Vodopod, which the émigré stated had been inspired by the appearance of U.S. submarines capable of diving to 400 m [about 1300 ft]. The émigré understood that Vodopod was part of the initial SS-N-16 project. Tests were completed in the early 1980s, but the émigré did not know whether this torpedo, broadly equivalent to the U.S. Mk 44, entered Soviet service. Given the report that the Mk 46 and Mk 48 propulsors were compromised to the Soviets during the 1970s, it seems likely that the Soviets have developed a faster thermal, lightweight, homing torpedo, closer in concept to Mk 46.

The acoustic seeker operated at 12 kHz with a maximum range of 1200 m [1300 yd]; the acoustic proximity fuze had an effective range of 1.5–3 m. Operating patterns: loiter (circular run, using passive homing), active homing, and a straight-line run-out at assigned depth. Maximum depth was about 400 m. The émigré reported that the design of the on-board computer

incorporated LSI but that test weapons used discrete transistors. Integrated circuits were first introduced in a 1975 torpedo, Tamga, which the émigré stated had the first Soviet on-board computer guidance system. At this time a vacuum-tube torpedo, Sapfir, was still in service (although work on transistorizing its acoustics was proceeding). Neither Tamga nor Sapfir has been identified with any published Soviet torpedo designation.

The torpedo could be braked by either a conventional parachute or a rotorhute (diameter 2.5 m, with four 0.7-m blades).

The émigré reported that as of 1976, 2 experimental high-speed torpedoes were being tested. One ejected a special substance (probably a polymer) from openings near its nose. The other, undescribed, was presumably a quiet thermal engine.

◆ 40-79

Thermal torpedo for air and missile delivery, in effect the Soviet Mk 46. This is 1 of 2 current missile-torpedo payloads. Presumably, it was bought instead of the electric torpedo described above and embodies the Mk 48 propulsion technology compromised in the 1970s.

◆ RAT-52

Dimensions: 14 × 140 in (approx) **Warhead:** 200–300 lb
Range: approx 600 yd (in water)

This rocket-propelled antiship torpedo entered service in the early 1950s. It was exported to the PRC and possibly to other allied nations. RAT-52 was air-dropped from several thousand feet and guided by gyro once in the water. It had a contact fuze. RAT-52 tended to porpoise, to break up upon hitting the water at high speed, or to lose its heading. In effect it was the direct predecessor of the later antiship missiles since the bomber launching it could operate from beyond the conventional anti-aircraft range of the target. Effective range from bomber to target, most of it in the air, greatly exceeded the figure given above. RAT-52 was withdrawn from Soviet service in the mid-1960s but may survive elsewhere.

UNITED KINGDOM

◆ Mk 8**

Dimensions: 21 × 264.85 in **Weight:** 3452 lb
Speed/Range: 45.5 kt/5000 yd or 41 kt/7000 yd
Warhead: 805 lb (torpex)
Power Plant: burner-cycle (steam torpedo)

Although this straight-running antiship torpedo is no longer in British service, it was probably supplied to many other countries as the antiship torpedo to supplement a homing antisubmarine torpedo. Mk 8** was also the standard British MTB weapon. Like the U.S. Mk 14, therefore, Mk 8 may still be in service in some smaller navies. This weapon sank the Argentine cruiser *Belgrano* in the Falklands War in 1982, the guided Tigerfish not having a reliable antiship mode at that time. Current Tigerfish are dual purpose, so Mk 8** is no longer in British service. Moreover, the Royal Navy feels that Sub-Harpoon is a superior antiship weapon.

Normal depth setting is 40 ft; maximum depth is 200 ft.

Mk 8** first entered service in 1927, although the version used in the Falklands was improved. By 1927, torpedoes were fitted with magnetic proximity fuzes (compensated coil rod or CCR). After World War II the Royal Navy planned to use a modified Mk 8 propelled by hydrogen peroxide (HTP): Ferry, later called Fancy, which was issued in 1954. However, the basic torpedo design was ill-adapted to HTP, and the project was abandoned after the loss of the submarine HMS *Sidon* in 1955. The HTP documentation was sold to the Swedish navy, where the design became the basis of the Type 61 torpedo. In addition, a Trumper active-homing torpedo was begun using Mk 8's components, but work ceased at the end of World War II.

Presumably, the remaining Mk 8** (often called Mk 8 because earlier versions of this weapon are long gone) in service are carried by torpedo boats. Mk 9, the companion destroyer/cruiser weapon, is extinct. Mk 8** was the standard West Ger-

man torpedo-boat weapon before adoption of wire-guided torpedoes. Probable current torpedo-boat users are Chile (the *Gua-colda* class), Denmark (the *Soloven* class), Greece (the "Nasty" class and former German torpedo boats), Norway (the *Tjeld* class), Saudi Arabia (the German Type 141 class), and Turkey (the *Kartal* and the Type 140 class). This torpedo may also survive in Brazil and Chile on board *Oberon*-class submarines; it is being replaced by the dual-purpose version of Tigerfish.

◆ Spearfish

Dimensions: 21 in × approx 19.5 ft **Weight:** 1850 kg [4077 lb]
Speed/Range: see below **Warhead:** 300 kg [661 lb]
Power Plant: HAP-Otto fuel (pump-jet propulsor, turbine engine; HAP is hydrogen ammonium perchlorate)

Spearfish is a heavy dual-purpose wire-guided torpedo selected by the Royal Navy as the successor to the current Tigerfish, in preference to the U.S. Mk 48/ADCAP. Spearfish, being developed by Marconi Underwater Systems, reportedly incorporates some Stingray technology. Spearfish reportedly achieved a speed of 70.5 kt in a trial in a Scottish loch, but reportedly speed at depth is substantially less. Back pressure at depth substantially reduces turbine output (compared to the output of a swash-plate engine as in the U.S. Mk 48); therefore, the torpedo is designed to make its maximum speed at depth and naturally runs much faster at shallower depths. Reports suggest that the engine operates at 2 speeds, search and run-out/attack. An endurance of 21,000 m has been reported.

Reportedly, the seeker uses multiple receivers some distance from the acoustic transmitter, for better directivity. That report suggests that the receivers are arranged around the sides of the torpedo's nose. In 1981 it was reported that Spearfish accommodates 5 times the computing capacity of Stingray.

Feasibility studies were conducted in 1977–79, leading up to Naval Staff Target (later Requirement) 7525. Reported requirements were a maximum speed of 55 kt; a diving depth of 3000 ft; and significantly improved self-noise, acquisition range, and lethality compared to Tigerfish. Very broadly, the new torpedo combines Stingray's seeker technology with a new thermal power plant for high performance. As no such power plant had been developed in Britain, the U.S. firm of Sundstrand was approached to provide a monofuel turbine. Reportedly, early in 1980 Marconi decided to increase Spearfish's speed to meet the problem posed by the Soviet Alfa-class submarine. In 1981 Spearfish was competing with the U.S. Mk 48/ADCAP, which was then credited with a speed of 60+ kt; Spearfish's maximum speed is, therefore, probably somewhat higher, i.e., about 63 kt. This uprating was achieved by replacing pure Otto-II fuel with the current HAP-Otto combination, output increasing from 550 to 1000+ HP.

In 1981 it was reported that a typical Spearfish would run out at 28 kt (to avoid alerting the target) at a depth of about 50 m (launch at 200 m) under wire guidance, then would enter a low-speed glide (passive search). The torpedo might opt to attack the first target detected or to continue searching. The torpedo, once it has found a target, can switch to active mode and accelerate to high speed to attack. Marconi claimed in 1981 that in the active mode the torpedo would typically be able to measure the size and aspect of the target, and that this capability would make Spearfish very difficult to decoy, since a real target would not suddenly change size and shape. Such sonar

imaging would also, presumably, make it possible for the torpedo to choose to hit at an optimum point along the submarine's length.

In mid-1990 it was reported that a Spearfish had achieved 81 kt at shallow depth (the official figure was 75+ kt). Since the torpedo is much faster at shallow than at great depth, it may run out toward its target, under wire guidance, at such a shallow depth, then dive to acquire the target. Such operation would be the torpedo equivalent of an up-and-over shot in air defense.

The decision in favor of Spearfish was made in 1980–81 (announced September 1981). It appears that Marconi offered a considerable savings if the Stingray and Spearfish programs were combined into a single British torpedo program. As of mid-1988, the production contract for Spearfish had been delayed because of proposals to include Dowty and British Aerospace as competitors. Tenders, which were to have been requested in mid-1989, were delayed to December 1989 to allow for competitive bids; the final bidders were Ferranti and Marconi. By the fall of 1989 the expected RN purchase was over 1000 (the earlier estimate was 770). Marconi manufactured 100 initial-production torpedoes.

As of mid-1990, the British Ministry of Defence was reportedly suspending orders (for up to 5 yr) in hopes that Spearfish would be adopted as a standard European weapon.

◆ Stingray

Dimensions: 325 mm × 2.6 m [12.75 in × 102.4 in]
Weight: 267 kg [588.5 lb] **Speed/Range:** 45 kt/8 km [8750 yd]
Warhead: 45-kg [99-lb] shaped charge
Power Plant: magnesium/silver-chloride seawater battery (pump jet)

The British replacement for license-built Mk 46s, Stingray was purchased in preference to the U.S. Mk 50. The manufacturer, Marconi, claims that Stingray is the first lightweight torpedo to incorporate a programmable general-purpose computer rather than a hard-wired special-purpose device. Stingray can,

Stingray torpedo (practice version) showing the pump jet just forward of the parachute housing. (Author)

The Marconi-Dowty Lightweight Test Vehicle (LTV), for a chemical propulsion system for a Stingray successor. Presumably, the nest of tubes near the tail of the torpedo constitutes the lithium-filled boiler, feeding the steam turbine just abaft it. The object forward of the boiler is the sulfur hexafluoride tank and pump. The front half of the torpedo is occupied by a computer, instrumentation (which replaces the warhead), and the sonar transducer in the nose. (Dowty)

Spearfish. The pump jet has a shroud. (Marconi)

therefore, be software-modified for different water environments and for different targets.

Homing is active acoustic, using dual frequency FM pulses and preformed beams. The torpedo can decide to switch between active and passive homing, using the latter mode, for example, if the target speeds up. The manufacturer, Marconi, emphasizes this ability to switch modes depending on circumstances, contrasting Stingray with a conventional torpedo that shifts between passive and active modes (if at all) using a preset homing criterion, or at a preset point. The seawater battery differs from most in recirculating its water internally, so that there is no external water scoop to make self-noise. The on-board computer selects a search mode. Target data can be compared to characteristics stored in the on-board computer, which calculates an interception path that takes into account the target's speed and maneuverability.

The seeker apparently uses preformed beams to search a considerable water depth very rapidly. Search is probably a snake pattern (rather than the helix of earlier torpedoes) at a single depth, since it is stated that the seeker can sweep the total water volume, from the surface down to maximum depth.

Stingray runs at a single speed (approximately equal to Mk 46's maximum speed), so Stingray can optimize its acoustic signature for a combination of maximum speed and maximum acquisition range. In March 1981 the torpedo was credited with depth performance equal to that of an Alfa-class submarine, presumably about 800 m. The torpedo is negatively buoyant: to avoid crashing into the bottom, Stingray must achieve substantial speed (for maneuvering) very early. The torpedo, therefore, starts up quickly upon hitting the water, and the rudders are located in the wash of the propeller for immediate effectiveness. Reportedly, Stingray can pull out of its initial (air-drop) dive in less than 4–5 sec, to avoid hitting the bottom in shallow water. There are alternative search patterns for deep and shallow water, and alternative broad- and narrow-band active ping options, presumably corresponding to long-range narrow pulses vs. shorter-range doppler.

As Stingray closes on a target, it uses highlights in the target's sonar image to measure target speed and aspect. Presumably, it employs proportional navigation (since it measures target speed). The terminal maneuver is a sharp turn into the target, to hit at right angles for maximum shaped-charged effect.

In shallow water, Stingray runs at a fixed height above the bottom.

Stingray uses a pump to recirculate hot, partly spent electrolyte; controlled amounts of cooled seawater are also run into the battery. The reaction inside is highly nonlinear and, therefore, difficult to control, but by varying the 2 factors, battery output can be varied to meet changing motor and acoustic requirements. The battery takes about 1.5 sec to fill with water and start after the torpedo enters the water. However, if the torpedo enters at too shallow an angle, the battery does not fill quickly enough, and the torpedo, which is tail-heavy when not filled, may porpoise.

When Stingray was offered in 1981, the U.S. Navy found the torpedo's speed unacceptable. Gould offered an alternative electric variable-speed power plant with a maximum speed of 62 kt. That figure may indicate the sort of performance expected of the current U.S. Mk 50.

Stingray came into service after the purchase of a long series of U.S. lightweights. The Royal Navy designed a heavy air-dropped torpedo, Mk 30 (Dealer B), but had to abandon it when the Gannet airplane was dropped in favor of ASW helicopters, which could not lift so heavy a weapon. Instead, the U.S. Mk 43 (now extinct) was bought, while a Mk 31 lightweight (proposed 1970) was developed. Mk 31 in turn was canceled in 1971, and the Royal Navy bought Mk 44 and Mk 46 Mod 2. At present the Royal Navy uses Mk 44 for shallow water and the Mk 46 for deep water.

Stingray studies began in 1964, the NSR 7511 staff requirement being issued in June 1968. It included shallow-water (presumably, for the continental shelf of the North Sea) capability.

Marconi received a contract for a seeker feasibility study in August 1969. The company apparently proposed something more, a torpedo that would modify seeker operation as it ran and that would be adaptable to a very wide range of water conditions. A design contract followed in 1977, and a production contract was expected in 1980. However, at that time the British defense budget was under pressure, and Mk 46 Mod 5 (NEAR-TIP) was suggested as an alternative. Stingray was selected instead; the stated reasons were that the U.S. torpedo had less effective homing, that its blast warhead was less effective than Stingray's shaped charge, and that Mk 46 Mod 5 could not operate in shallow water.

Production began in April 1981, with orders for 280 and then for 550. Some Stingrays were sent to the South Atlantic in 1982 (HMS *Antelope* had 4 on board when she was sunk), but they were not used. The torpedo officially entered service in 1986; the British government placed an order for 2500 Stingrays in January 1986. On 19 October 1985, in its first live-warhead test, a Stingray dropped from a Nimrod aircraft destroyed a double-hulled submarine, HMS *Porpoise*, moored at a depth of 65 m in the Mediterranean. Total running time to the target was about 3 min. The extent of damage to the submarine seems to have been surprising. The torpedo was expected to cut a small-diameter (albeit fatal) hole in both hulls, after which the submarine would have been raised for examination. Instead, it was so completely destroyed that it could not be raised. This result may indicate the power of all current lightweight torpedoes equipped with warheads made of modern explosives.

Several improved versions have been suggested. In 1981 a possible Mk 2, incorporating Spearfish's seeker technology, was mentioned. More recently a new version powered by the sort of closed-cycle engine used in the U.S. Mk 50 (Barracuda) has been proposed. There have also been suggestions that the Torpex warhead be replaced by PBX 104, a more powerful plastic-based explosive used in U.S. weapons.

About 1988 a U.S. estimate of the unit cost of this torpedo was \$440,000. Current export customers are Egypt, Norway, and Thailand.

Toward the end of Stingray's development program, Marconi analyzed a variety of alternative propulsion systems, both electric and thermal. The company proposed construction of a series of Fast Lightweight Test Vehicles (FLTVs), to be powered by the type of closed-cycle SCEPS plant employed in the U.S. Mk 50. In 1985 the British Ministry of Defence placed a contract with Dowty Fuel Systems for a land-based demonstrator, and by 1989 construction was well advanced; completion of a plant packaged for torpedo use is scheduled for 1991. The Ministry then asked Dowty and Marconi to submit a proposal for a torpedo test unit, and a development cost plan was submitted on 26 August 1988. Marconi proposes a Lightweight Test Vehicle (LTV), presumably using a modified Stingray hull.

◆ Tigerfish (Mk 24)

Dimensions: 533 × 6464 mm [21 × 254.5 in]

Weight: 3420 lb **Speed/Range:** 35 kt/23,000 yd; 24 kt

Warhead: 750 lb (magnetic proximity fuze for surface targets; impact fuze for submarine targets)

Power Plant: twin silver-zinc batteries (2-speed motor)

Tigerfish began in 1959 as Project ONGAR, for a faster and more sophisticated antisubmarine torpedo. An order for 100 was placed in 1967 with the Royal Navy Torpedo Factory (RNTF). ONGAR was a 2-speed electric torpedo with wire guidance and a passive terminal sensor. Because the torpedo was heavier than water, it used retractable wings to provide lift at low (search) speeds and also to improve roll control. Acceptance trials in 1969 were so unsuccessful that a special Torpedo Project Executive was established, and the contract transferred to GEC. The wide-beam seeker (which had large nulls in its beam pattern) was the major problem. Marconi was asked to design a new narrow-beam seeker and a more powerful on-board computer that could take over more of the guidance role. Marconi was also asked to develop a second version, Mod 1, with an

Tigerfish. This torpedo uses propellers. (Marconi)

antiship seeker. This effort also encountered problems, this time in the interfaces with the shipboard tactical-data systems and with actual torpedo control. RNTF was closed, and production passed to Plessey.

In 1973-74 a second series of trials showed that the weapon could perform as expected but that overall the system's reliability varied wildly, from 20% to 80% (40% average). The torpedo depended very heavily on data provided by the submarine but tended to dip and snap its guidance wire after being launched. In 1974 the overall production contract passed to Marconi since the major problem was not the hull of the torpedo but rather its control system (which had been Marconi's responsibility from the start). A redesigned Mod 1 passed trials in 1978, but the main version, Mod 0, was still unsatisfactory. It failed provisional fleet acceptance trials in 1979 but was issued to the fleet beginning in August 1980.

In 1982, 2 of 3 Mod 1 torpedoes fired at the burnt-out hulk of the LSL *Sir Galahad* did not hit because their batteries failed.

In 1983 the controller of the navy awarded Marconi a contract for a Mk-24 Consolidation (i.e., get-well) Program. In 1985 test shots showed a satisfactory 80% reliability. Part of the get-well program was replacement of the existing wire dispenser with a pair of dispensers, one on board the submarine. Demonstrations have shown that, with this dispenser, the submarine can evade after firing without breaking the guidance wire. Some Stingray technology has also been incorporated into the modified weapon, Mk 24 Mod 2, and all 600 war-stock Mk 24s had been modified by 1987.

This weapon replaced the earlier Mk 20E (Bidder), a dual-purpose passive-homer that entered service in the mid 1950s on board both frigates and submarines (1810 lb, 196-lb warhead, 20 kt/12,000 yd). The surface version was abandoned because its preset attack data system proved unreliable. No British surface ASW torpedo was available until 1964, when Plessey began to deliver license-built U.S. Mk 44s. Mk 20E remained in submarine service through 1970. Mk 22 was an abortive wire-guided version of Mk 20; VSEL produced a private-venture version in 1970. Mk 23 (Grog) was a modified Mk 20 with a wire-guidance section between the battery compartment and afterbody, issued from 1970 onward as an interim torpedo pending the appearance of Mk 24 (2000 lb, 28 kt/8750 yd).

Tigerfish typifies the European type of antisubmarine torpedo, operating passively at relatively low speed to avoid alerting the targeted submarine. For example, in 1981 it was reported

that Tigerfish was 15-20 dB quieter (in self-noise) than Mk 48. Passive approach died because many submarines themselves became too quiet to be detected passively. Once torpedoes approached actively, they had to be able to catch an alerted target: hence the high-speed Spearfish.

Tigerfish Mod 1 (dual-purpose) has been supplied to Brazil. Mod 2 is the improved British version currently under development.

In 1990 Cardoen of Chile obtained a license to manufacture Tigerfish, initially for the Brazilian, Chilean, and Venezuelan navies.

TORPEDO LAUNCHERS

◆ Submarines

Strachan & Henshaw has been the prime submarine torpedo-tube contractor since 1972.

Until 1945 the Royal Navy used HP air directly to fire its torpedoes. Postwar the RN began to use its submarines for ASW, and they had to be able to fire at well below periscope depth. The navy, therefore, adopted dual-pressure gear, in which lower-pressure air was used for control, and the limited supply of HP air used exclusively to eject the torpedo. This system was installed in modernized submarines and also in the new-construction *Porpoise* and *Oberon* classes.

HMS *Dreadnought* introduced the U.S.-type water-ram system, which is independent of depth. HP air pushes a piston, which in turn pushes a water piston that pushes water into the torpedo tube. The next stage is to use a rotary (water) pump, driven by an air turbine, as the prime mover. This is more compact than the earlier water-ram system and has been, therefore, adopted in the new British *Upholder*-class diesel-electric submarines. This system is also used by the Dutch navy, and it has been adopted for the Australian Type 471.

SURFACE SHIP SYSTEMS

◆ STWS Series

STWS-1 is an underwater weapons system including an adapted U.S. Mk 32 torpedo tube, firing Mk 44 and Mk 46 torpedoes only. Normally, AIO target data are fed into the STWS, but it can also take sonar data directly, and data can be fed in manually in a backup mode. Operating modes: manual, aided manual, automatic. In the automatic mode STWS-1 uses sonar data to compute an FCS solution, which may take time. Hence the provision for a manual mode for snap-shots. In the aided manual or automatic modes, STWS displays the course to steer to get to the point at which a torpedo will be within acquisition range of the target, and it also shows the distance to run to the firing point. The PWO (Underwater) selects which torpedo to fire (STWS-2 carries both Stingray and US) and the torpedo search-pattern parameters (range, depth, course).

STWS-1 appeared about 1975, in effect as a replacement for the Limbo long-range mortar. It was installed on board the Type

STWS-2 on board HMS *Glamorgan*, 1985. (R. Cheung)

42 missile destroyers, the Type 21 frigates (installed after completion), and the Ikara, Exocet, and Sea Wolf *Leander* frigate conversions. It also equips the first 2 Type 22 frigates (*Broadsword* and *Battleaxe*).

STWS-2, which can fire the Stingray torpedo, appeared in 1981 on board Type 22 frigates. It incorporates the PMW49A triple torpedo launcher, which carries 4 prominent hatches and a control box (muzzle to breech) on each tube. The foremost hatch (No. 1) contains the Stingray lanyard solenoid unit. Hatch No. 2 contains the Stingray battery port cover remover. Hatch No. 3 contains the Mk 46 lanyard solenoid unit, and Hatch No. 4 contains the plug puller unit. Large boxes between Hatches 1 and 2 are distribution boxes. A pipe running along the length of the upper tube is the charging hose (torpedoes are fired pneumatically, from air flasks locked into the tube breeches). Torpedoes are fired when the tubes are trained 45 deg from ahead. There is a training handle at the breech end of the tube, although tubes are normally trained remotely. Muzzle doors are electrically operated, with a box at each muzzle.

STWS-3 is currently under contract.

◆ MTLs

Magazine Torpedo Launching System, for the new Type 23 ("Duke" class), supersedes the STWS series. MTLs is located inside the hull for better weather protection and for minimum torpedo handling. The torpedo is launched directly from the magazine space, necessary settings being fed in from the operations room via the ship's data bus. By colocating the launcher with the magazine, MTLs also serves the helicopter hangar. This arrangement was first tried in the U.S. *Knox* class, whose design was also an attempt to reduce manning. MTLs is manufactured by J&S Marine.

UNITED STATES

The current standard submarine torpedo caliber is 21 in; 19-in weapons were developed only so that they could swim out of 21-in tubes using air ejection (i.e., limited in firing depth). However, the new *Seawolf*-class will have 30-in tubes (the prototype is being installed on board the submarine *Memphis*). The increased caliber will permit silent (i.e., swim-out) firing of existing weapons, but presumably a 30-in weapon is planned. Greater diameter would make for much better acoustic performance since the area (and, therefore, presumably the gain) of the nose transducer would be about doubled. A 30-in torpedo might also enjoy a more favorable length: diameter ratio, for better hydrodynamic performance.

It was reported in mid-1989 that work had already begun on the new 30-in torpedo. The reported goal is a very quiet torpedo capable of loitering while listening, then striking, similar to Tacit Rainbow. The new weapon is intended for very long stand-off distances (equivalent to OTH-T in antiship operations).

In September 1990 Honeywell announced that it was spinning off most of its defense divisions, including the torpedo division, into a new company, Alliant.

◆ Mk 14 Series

Dimensions: 21 × 246 in **Weight:** 3209 lb
Speed/Range: 31.1 kt/9000 yd or 46 kt/4500 yd
Warhead: 643 lb **Power Plant:** steam turbine

Mk 14 was the standard U.S. submarine torpedo of World War II, remaining in use through the 1970s. Mk 14 was probably supplied to many Allied navies on board ex-U.S. submarines, and some of these torpedoes may remain in service. Although early Mk 14s had magnetic exploders, all surviving examples are contact-exploded.

About 13,000 Mk 14 torpedoes were manufactured during World War II (with others built prewar), together with 9700 of the simpler 1-speed Mk 23 version (46 kt only). Mk 14 was declared obsolete in the late 1950s or early 1960s, when U.S. submarines were all assigned to the ASW role and when the hydrogen-peroxide Mk 16 became available in quantity to provide the few antiship weapons required. However, Mk 14 was

reactivated in 1969 and was withdrawn again only as dual-purpose Mk 48s became available.

Mk 16 was never exported. Over 1700 were made postwar and remained in service until 1975. Mk 16 was the same size as Mk 14 (though it weighed 4000 lb), but hydrogen-peroxide propulsion enabled Mk 16 to achieve 11,000 yd at 46.2 kt and to carry a 746-lb warhead. The final version was Mod 8.

◆ Mk 15 Series

Dimensions: 21 × 288 in **Weight:** 3841 lb
Speed/Range: 26.5 kt/15,000 yd or 33.5 kt/10,000 yd or 45 kt/6000 yd
Warhead: 825 lb
Power Plant: steam turbine

Although no longer carried by U.S. destroyers, Mk 15 is probably the torpedo fired from surviving ex-U.S. quintuple surface tubes in ships transferred abroad.

About 9700 Mk 15 torpedoes were manufactured in 1940–44.

◆ Mk 37 and NT37 Series

Dimensions: 19 × 135 in **Weight:** 1430 lb
Speed/Range: 26 kt/10,000 yd or 17 kt/23,500 yd
Warhead: 330 lb **Power Plant:** battery

Data apply to Mk 37 Mod 0.

Mk 37 was the standard U.S. submarine-launched antisubmarine torpedo of the 1960s, and it survives in many other navies. For example, the Argentine submarine in the Falklands fired a Mk 37 at a supposed (and almost certainly false) British submarine contact. Design began in 1946. Evaluation of the first pilot lot (30 torpedoes, 1955–56) led to the first production order (for 90). Mk 37 was accepted into service in 1959. In U.S. service, it was superseded by Mk 48. Mk 37 was always a single-purpose torpedo because it was too slow to catch fast surface ships, and because its homing system was ill-adapted to passive operation against surface targets. It was also too slow to deal with nuclear submarines; hence the urgent development of the much faster Mk 48. In recent years Honeywell has offered kits to convert Mk 37 into various versions of NT-37 (see below). The Mod 1 version was the first major U.S. submarine wire-guided torpedo.

Operating modes are predicted-intercept, corrected-intercept (i.e., mid-course corrected run), and bearing-rider (see the discussion of the Mk 101 FCS as modified with angle solver Mk 18). Homing can be active or passive or a combination. The torpedo follows a preset horizontal search pattern to circle left or right or to snake. Vertical search can only be upward from the running-depth ordered, within preset limits. Speed is preset as high or low.

Versions:

Mod 0 Original free-running passive/active version (1957). It was carried by submarines. It was also the version carried briefly by FRAM II and *Forrest Sherman*-class destroyers, and exported for some foreign surface warships. Attempts to adapt U.S. forward-firing surface-ship tubes to fire the wire-guided version of the torpedo were unsuccessful. Hence the attempt to use stern tubes in the transoms of frigates. Dimensions: 19 × 135 in (1430 lb, 330 lb HBX-3 warhead). Range: 23,500 yd/17 kt, 10,000 yd/26 kt. The torpedo could also combine periods at both speeds. Depth limits: 4–1000 ft. Trajectory: snake or circle search under gyro control followed by helical search in depth.

Mod 1 Wire-guided version, resulting from a performance and reliability program begun 1958, followed by a development con-

Mk 37 torpedo. (U.S. Navy)

tract awarded to Vitro in June 1959. BuOrd awarded a development contract to Vitro. Final subsurface demonstration shots were fired by *Gudgeon* and *Blenny* in August and October 1960, and the above-water version was installed on board the destroyer *Robert K. Huntington* (DD 781). The internal wire reel is housed in an extender section between the afterbody and the tailcone. The effect of lengthening the torpedo to 161 in is to reduce its speed to 15.8 or 23.8 (high-speed setting) kt. There was only enough wire to guide the torpedo to 13,500-yd range. The torpedo accepts course changes in 2 deg/signal increments, and it can be command-enabled. It sends status signals (fin velocity switch activation, enable acquisition, and loss of target) back down the guidance wire. Guidance modes were bearing-rider and corrected-intercept. This version had a new helical snake search pattern for use when water depth was greater than 150 ft, allowing for a sinusoidal path both in depth and in the horizontal plane. This path varies azimuth by 2700 ft and depth by 1000 ft (the previous version had searched a 550-ft interval in depth). This version also had provision for laminar point steering; the laminar point is used in fire control computation of torpedo position, rather than body coordinates, in order to optimize acoustic acquisition. The laminar point is a point within the acoustic envelope located on an imaginary centerline, forward of the actual torpedo position, about which maximum search coverage is obtained. Enable range was 300–9500 yd. Acquisition range was 700 yd. This version was carried by many U.S. and foreign submarines. It (or Mod 2) was planned for the U.S. *Garcia*-, *Brooke*-, and *Knox*-class frigates; it would have been fired out of their transoms. This arrangement seemed necessary to allow the guidance wire to pay out properly. A few ships actually had the tubes installed, but they were soon removed. Long transom tubes for homing torpedoes (in some cases, for Mk 48) were a feature of many U.S. destroyer and frigate designs of the 1960s. Mod 1 was adopted in place of the less-flexible wire-guided Mk 39 Mod 1, a pure bearing-rider, running out at 50-ft depth (and then using its 24.5-kHz passive seeker). Mk 39 was also slower (13,000 yd/16 kt) and had a smaller warhead (130 lb of HBX-3). It was restricted to 10–100-ft depth.

Mod 2 Wire-guided version developed from Mod 1. This is the submarine-launched version that survives in foreign navies. Torpedo length is 161 in, weight 1690 lb. A 2000-torpedo 3-yr conversion program delivered the first Mod 2 in March 1967. About that time it was decided that all Mod 0 and Mod 1 torpedoes would be converted to the new configuration. The major improvements were increased acoustic acquisition range at deep depth, reduced susceptibility to surface-seeking at shallow depths, improved shallow-water performance, and better reliability and maintainability. Mod 2 used a new ceramic transducer in place of the previous magnetostrictive one; the magnetostrictive unit lost sensitivity at greater depth (Mod 2 was rated at 900+ yd at 900 ft compared with 400–500 yd at that depth for Mod 1). The shallow-water homing improvement was to discriminate against reverberation at close range, where most spurious reflections are to be found. The torpedo could be set to run at constant depth (40, 100, 150, or 200 ft) while homing (before terminal maneuvers), when above 100-ft depth in deep water, or when in shallow water. It was provided with preset operating depths of 200, 150, 100, and 40 ft for shallow water. The anticapture (anti-surface-homing) circuits were disabled when the torpedo ran below 200 ft in deep water or when it was homing passively. The anticapture feature was tested in 1966.

Mod 3 Refurbished Mod 0 (free-runner) specifically for the Spanish navy's *Baleares*-class frigates, fired out of tubes in their transoms. Each ship carries 12 torpedoes.

A Mk 37 improvement program begun at NUSC Newport in 1971 led to test runs in December 1973. This project presumably competed with the Northrop/Honeywell NT-37 program. NUSC fitted a new high-density battery, a more powerful motor, and new quieter propellers, as well as a new homing panel to improve performance against streamlined submarines (with

their reduced sonar cross sections). NUSC claimed greater active-mode sensitivity against valid targets without any increase in the false-alarm rate. The new propellers, more steeply raked than their predecessors, lengthened the torpedo by 3 in. It is not clear to what extent the NUSC program was actually implemented.

In 1968 Northrop Corporation began work on improvements to Mk 37, in cooperation with the Naval Torpedo Station at Keyport, Washington, replacing the existing silver-zinc battery with the Otto fuel engine of a Mk 46-1. Speed increased by 40%, and range by 150%. For a service modified torpedo (NT37C), the published figures are 40% greater speed, 125% more range, and about 80% more endurance.

Northrop carried the Mk 37 conversion program through about 1980, when this activity was transferred to Honeywell. The designation of the modified torpedo, NT37, still reflects the company's involvement.

The program was approved in 1968, and acoustic improvement tests began in 1969. Tests of the NT37C systems were conducted in 1970, followed by tests of the submarine systems in 1971, preproduction and production verification in 1972, and certification of readiness for service in 1973 (NT37C version). Improvements included not only the enormous increase in speed and range but also true dual-purpose capability: because NT37C was so fast, it could duplicate the straight run of, say, a Mk 14. NT37C can be set in 3 modes: (i) straight running at high speed with depth control; (ii) delayed homing, the torpedo running straight but searching if it misses (or beginning its search at a preset range); (iii) full passive homing, as in the original Mk 37. By 1977 NT37C was in service in several NATO and South American navies, and in February 1976 Norway ordered kits for conversions of its Mk 37s.

The next step was a new homing head. NT37C plus the new acoustic system is designated NT37D.

NT37D plus a new guidance system, the fully modernized torpedo, is NT37E. It incorporates a self-noise-reduction nose assembly (with baffling to protect the transducer from engine and hull noise, and with a new nose shape to reduce flow noise), a solid-state acoustic panel (to replace the vacuum tubes of the original Mk 37), and a new digital (vice analog) autopilot. In one version, the autopilot can be programmed to navigate the torpedo to specific geographical coordinates. Honeywell claims that these modifications double the active detection range and nearly double the passive detection range against fast targets, partly because with less flow noise the acoustic system can be made more sensitive (the company cites test results that showed an improvement of 50–90% in the active target-acquisition range, and of 100–200% in the passive target-acquisition range). The company also claims better performance at higher speed and in shallow water, in both cases thanks to noise reduction. On a subtler level, Mk 37 tactics are fixed; NT37 tactics are programmable and, thus, less easily predicted.

The new nose and acoustic panel were first tested in 1980, developmental and operational tests of NT37E following in 1982 and 1983. In 1980 Canadian/Norwegian/Dutch trials on the *Nanose* acoustic range showed a 71% success rate in 17 runs; an operational evaluation in the North Atlantic showed 88% success in 8 runs. Operational demonstrations in 1981 showed 100% success in 18 runs. Canadian guidance-and-control trials in 1982 (*Nanose* range) showed 100% success in 5 runs.

NT37F is the main current (1990) Mk 37 upgrade version. The principal change is some guidance improvement. Compared to Mk 37, NT37F achieves 40% higher speed, 125% longer range, and 100% longer shallow-water passive and active detection ranges (a diagram shows about 90% longer passive-detection range). Special baffling and a new nose shape protect the sonar transducer from engine and hull noise at high speed and near the surface. The fixed analog logic of the original Mk 37 is replaced by a digital programmable control system. Additional antiship run patterns are added to the control system. The manufacturer claims that major service work is reduced from an 18-

month cycle to once every 6 yr, partly through the introduction of a self-testing acoustic panel and a more reliable control system.

NT37G is a next-generation torpedo (rather than a modernized Mk 37) with a larger warhead, a proximity fuze, and increased speed (a modified engine).

Given the large number of Mk 37 produced, Honeywell (which currently has rights to NT37) has offered foreign customers a variety of modified versions in an NT37 series; these modifications could be applied to existing torpedoes. Honeywell also offered a modified Mk 37 for the abortive U.S. requirement for an inexpensive surface-only torpedo (see Surface Torpedo below). By late 1983, about 500 torpedoes in 5 navies had been upgraded to NT37C configuration.

Mk 37 was supplied to at least 16 navies. As of 1986, NT37C was in service with the navies of Canada, Israel, the Netherlands, Norway, and Peru.

Mk 37s have also been rebuilt both as Submarine-Launched Mobile Mines Mk 67 and as Standoff Weapons Mk 32. For details of Mk 67, see the Mine Warfare section. The standoff weapon is intended for use from SEAL Swimmer-Delivery vehicles Mk IX, to attack surface ships in harbors. The standoff weapon was introduced into fleet service during FY87. (The SEALs also have both limpet mines and Underwater Demolition Weapon EX-33, a 1200-lb charge that can be laid under major or nested ship targets in harbor.)

◆ Mk 44

Dimensions: 12.75 × 100 in **Weight:** 425 lb
Speed/Range: 30 kt/6000 yd **Warhead:** 75 lb
Power Plant: seawater-activated battery (30-HP motor)

Data are for Mod 0. Mod 1 is 101.3 in long, 433 lb, with a 73-lb warhead.

Mk 44 was formerly NATO's standard lightweight homing torpedo, the payload for which ASROC and Ikara were designed. Development began about 1952 and was completed in 1956. Production began in July 1958, with first delivery in FY60. Mk 44 was designed primarily to attack submarines with speeds of up to 17 kt (i.e., postwar diesel-electric types); it replaced the 15- or 21-kt Mk 43.

Mk 44 is a pure active homer, with an acquisition range of 1000 yd (max; 650 yd average). This compared to 800 yd (max) for the previous lightweight homer, Mk 43. Maximum homing range is 3000 ft. Operating depth is 50–1000 ft. Prelaunch fire-control settings: mode (surface or air/ASROC), initial search depth, search floor, and shallow or deep dive angle. The search pattern is helical, with a sink rate of 25 ft/sec and a 440-ft diameter. Initial search depth is 50, 150, 250, 450, 650, or 900 ft; search floor is preset at 150, 250, 450, 650, or 900 ft. After a runout or initial dive (at a 30-deg angle), the torpedo may execute a flat search turn at the initial search depth; it then runs

A Mk 44 torpedo on board HMS *Invincible*, 1984. The parachute pack is immediately abaft the shroud used to control the torpedo. (R. Cheung)

through the helix at a dive or climb angle of 4.5 deg, executing a flat turn at the bottom after a 6- or 7-deg dive, and then climbing back up (with an initial climb angle of 6 or 7 deg). It continues up and down along the helix until it exhausts its 6-min endurance.

Mod 0 has no run-out feature; Mods 1, 2, 3, and 4 run out about 1000 yd before beginning a helical search.

In U.S. service, Mk 44 was replaced by Mk 46 from about 1967 on, but many Mk 44s remain in service in foreign navies, and the U.S. Navy probably retains a large stockpile. A total of 10,583 Mk 44 were made in the United States under the FY59–65 programs (the last was delivered in December 1967), and this weapon was also manufactured in Canada, France, Italy, Japan, and the United Kingdom.

In 1986 Honeywell offered a modernization kit for Mk 44. The existing nose was replaced by a new one incorporating ceramic rather than magnetostrictive transducers, in a planar array (rather than using an acoustic window). The planar array incorporates a preamplifier, and the analog transmitter and receiver of the existing Mk 44 are replaced by digital devices. Claimed improvements include an increase in MTBF from 160 to 3000 hr and a 75% increase in detection range; minimum shallow-water search depth is reduced by 47%. Volume search rate is tripled. Honeywell claims that the addition of a notch filter reduces boundary-layer attacks. A new range gate reduces acoustic false alarms. A new search mode is added for intermediate water depths.

◆ Mk 45F (Freedom Torpedo)

Mk 45F has been deleted because it was never sold (a sale to Turkey was aborted because of the 1974 embargo). For details, see the last edition.

◆ Mk 46

Dimensions: 12.75 × 100 in (15.3-in fins) **Weight:** 508 lb
Speed/Range: 12,200 yd/45 kt at 50-ft depth; 10,100 yd/45 kt at 1500-ft depth
Warhead: 96 lb of H-6
Power Plant: Otto-fuel piston engine

Data apply to Mod 1 as delivered (1968). Operating depth is 20–1500 ft, and acoustic homing range is 1600 yd maximum (1300 yd average) with a 30-kHz sonar. Mod 0: 568 lb, range 9500 yd at 50 ft, 7000 yd at 1500 ft (40 kt at 1500-ft depth).

Mk 46 is now virtually the standard NATO lightweight torpedo. In U.S. service it replaced Mk 44. Mk 46 is much faster, dives deeper, has 60% greater maximum acquisition range, and can be dropped at up to 500 kt.

The final Development Characteristic was issued in June 1956 for a torpedo to attack 30-kt (i.e., nuclear) submarines, with dimensions of about 15 × 98 in, and 50–1000-ft operating depth. A feasibility study was completed in December 1956, and a development contract was awarded to Aerojet in May 1958. The Mk 46 operational requirement was issued in November 1960, and production of Mod 0 began in 1963 (it entered service in 1964). As of 1960, the design requirements for Mk 46 included an acquisition range of 1200 yd and a maximum speed of 45–50 kt. Unlike Mk 44, Mk 46 would not have to conduct a helical search. Running horizontally at a depth of 750 ft, it could sweep out all depths down to its maximum of 1500 ft. In a technical evaluation (September 1962–June 1963) Mod 0 demonstrated 70% reliability and the ability to attack submarines with speeds up to 20 kt (computer simulations showed that it could attack at target speeds of up to 33 kt, but that could not be tested). Operational evaluation (April–November 1964), involving 172 firings, showed that acquisition probability in deep water without interference sources or countermeasures was 60% and that hit probability after acquisition was 77% against submarines and 88% against mobile targets; demonstrated reliability was 75%. The first Mod 1 production contract was issued in 1965, and Mod 1 (the first main-production version) was first tested in 1966.

Mod 1 evaluation (November–December 1965) demonstrated

that, if placed within acquisition range, the torpedo had an 86% probability of acquiring, attacking, and hitting a target. Compared to Mod 0, Mod 1 was intended for better reliability and maintainability and lower production costs, largely through introduction of a high-energy, liquid, monopropellant fuel (Otto fuel); Mod 0 was powered by a solid-fuel turbine. In addition, the tilting shroud ring used to steer Mod 0 was replaced by 4 movable fins. Mod 1 and later versions (i.e., all current versions) use a 5-cylinder swash-plate engine, with 2 power strokes per revolution. Otto fuel is ignited in a combustion chamber, and the resulting gas flows into the piston engine.

Mk 46 was designed for either active or passive/active operation; in the latter mode, the torpedo listens for target-radiated noise. If it receives none during a short preset time, it shifts automatically to active search. In addition, the vertical-search beamwidth is controlled by the onboard computer or autopilot: narrow for shallow water (and during the attack phase), to avoid bottom and surface reflections, and broad in deep water.

Initial information is entered into the autopilot, which turns on the computer once the torpedo has passed its preset enable distance. The computer in turn provides control signals and a time base. It controls the active sonar and interprets its outputs, setting a range gate. Once a range gate is set, 2 valid echoes in the gate are taken to verify that a target is present, and the computer begins to send pitch commands to the autopilot. The computer also carries the tactics for search and re-attack in the event that a target is lost or an attack fails. Comparison with later torpedoes, such as Murène, shows what the computer does not do: it does not track several targets simultaneously to decide which is worth attacking (and which is a decoy), and it uses preset tactics. The difference is presumably entirely a function of the much greater power of newer computers.

Prelaunch firing information includes homing mode, initial search depth, ceiling depth, search pattern, and course heading (some versions incorporate a floor depth, to avoid hitting the bottom). At least in the current Mod 5, information can be entered up to $\frac{1}{4}$ sec before launch, and there is no warm-up prior to firing.

The 2 primary search modes, snake and circle, contrast with those of earlier torpedoes, which searched in a helix, sinking or rising as they turned. Presumably, this change reflects Mk 46's longer sonar acquisition range, which provides a wider FOV at any depth. Surface tubes are generally programmed for snake search but can select circle under urgent or close-attack conditions. Aircraft and ASROC launches are automatically set for circle. Helicopter-launched torpedoes can be set to circle or snake. Initial depth is 1 of 6 options, depending on the depth and course of the target submarine. Operating ceiling is automatically set at 50 ft for surface-tube launch (so that the torpedo cannot attack the launching ship) but is selectable for other modes. Course headings are programmed only for snake search. There are 5 headings for a surface tube but 12 for a helicopter, so the latter can attack in any direction from the hover.

Upon hitting the water, Mod 1 could run out along a gyro-set bearing, or it could conduct a circular or helical search. When dropped from an aircraft or from an ASROC missile, it immediately began to search. It, therefore, had to be dropped almost directly over a submarine contact. Mod 1 was adapted to 2-helicopter tactics, 1 helicopter using its dipping sonar to vector the other.

About 1970 existing Mod 1 torpedoes had computer logic changes to improve their performance against slow and/or periscope-depth targets.

Other versions:

Mod 1 Phase 2 had improved capability in shallow water and against countermeasures. It had all of the Mod 2 improvements except HATS (see below). It and Mod 2 became available to the fleet in the latter half of 1971. At this time work began on a proposed much-deeper-diving Phase 3, with better countermeasures resistance, which could have been launched in water as shallow as 200 ft (i.e., which pulled out of its initial dive more

quickly). Phase 3 was probably conceived as an interim approach to what became Mk 50.

Mod 2 (1970) had additional computer logic improvements and a new autopilot. It could re-attack after losing a target or chasing a decoy. Mod 2 was specially adapted to a new single-helicopter attack system (HATS, the helicopter attack tactical system), in that the helicopter FCS could preset its search mode, search depth, and run-out bearing before firing. The torpedo, therefore, had 2 search modes, AIR/ASROC (search from water entry, as in Mod 1) and HATS (in which the torpedo ran out in snake mode). The autopilot was modified so that the gyro settings previously available ($0, \pm 35, \pm 70$ deg) were supplemented by $\pm 95, 120, 150$, and 180 deg so that the helicopter could launch while hovering into the wind regardless of target bearing.

Mk 1 and 2 equip numerous foreign navies, including those of Australia, Brazil, Canada, France, Greece, Israel, Italy, New Zealand, Spain, the United Kingdom, and West Germany. These versions were manufactured from 1965 through 1981.

Mod 3 was a version with control system improvements, canceled.

Mod 4 is a torpedo built specifically as a payload for the CAPTOR (Mk 60) mine.

NEARTIP (Mod 5, the Near-Term Improvement Program) was very nearly a completely new torpedo, employing either entirely new or greatly modified seeker (sonar transducer, transmitter, and receiver), guidance, and propulsion. Sonar improvements were intended specifically to counter submarines with anechoic coverings, specifically Soviet boats. The correlation channel used to determine whether sounds detected by the sonar were in fact echoes of the pulses it sent was improved, to make up for the reduction in signal-to-noise ratio caused by the anechoic coverings. The transmitted waveform was changed to make better use of target doppler for signal processing. Signal-processing logic was improved, particularly to reject false targets. At the same time, reverberation effects in shallow water were reduced, so self-noise could better be measured and disregarded. All operation is now digital, with improved stability and precision. Mod 5 incorporates an improved digital computer whose master clock times all torpedo functions. Improved search and re-attack patterns are stored in the computer's EPROM, for better countermeasures resistance (discrimination) and target acquisition and reacquisition. A second roll pendulum improves pullout from dives and is also better for shallow-water launch.

Finally, the torpedo's motor was modified to provide a second (lower) search speed. The lower speed reduced self-noise and, thus, increased the available signal-to-noise ratio at the torpedo's sonar processor. The slower speed also increased the total torpedo endurance (in terms of time) by 30–50%. Once the torpedo has locked onto its target it still attacks at the same sort of high speed provided by the original Mk 46. The fuze was revised to function even if the torpedo struck the target at a shallow angle.

The U.S. Navy introduced the first of 2 shallow-water modifications in 1984, to improve performances against slow submarines at periscope depth in both deep and shallow water. Normally such targets are difficult to engage because they provide little doppler (which the torpedo uses to distinguish them from background noise) and because the torpedo has difficulty dealing with reflection (both of its pulses and of its self-noise) from the surface. The modification apparently consisted of a more coherent transmitter and better steering logic.

Honeywell, the manufacturer, developed a further shallow-water modification of its own. The success of the program is presumably demonstrated by a photograph, recently published, of a surfaced submarine target hit by a Mk 46 Mod 5. The target may have been fitted with some noise source, but even so it presented all the problems of a surface-ship target. The torpedo's success suggests that it can be used in an alternative anti-surface ship mode so that, for example, torpedo-carrying missiles like ASROC can be employed against surface targets. Although these missiles are generally far slower and far less efficient than their specially designed antiship counterparts,

torpedo-carrying missiles have 1 interesting potential advantage: they may be able to drop their weapons outside the effective range of close-in weapons. These points would apply more strongly to fast submarine-borne weapons such as Sea Lance.

The warhead was also improved; it was a Mk 103 with PBXN-103 explosive.

Honeywell offers a retrofit kit to convert existing Mod 1 and Mod 2 torpedoes to Mod 5 standard. Presumably, this is the kit supplied to the U.S. and foreign navies. It is a third less expensive than a new Mod 5 torpedo. The kit includes a Mod 2 transducer for increased detection range against an anechoic-coated submarine (required only if a Mod 1 is to be upgraded to Mod 5 standard); a new receiver and transmitter for increased output and sensitivity, with valid-echo logic optimized to classify and reject false contacts (for effectiveness against slow, shallow targets); a new digital-computer control system, with new attack and re-attack logic; and a 2-speed valve for 2-speed propulsion.

Mod 5 requires overhaul at 4- and 8-yr intervals (engine tear-down every 4 yr).

Mod 6 (1989) is a slightly improved Mod 5 forebody with an existing Mod 4 afterbody, for use in Captor (Mk 60) mines.

NEARTIP began in October 1972, technical evaluation being completed in November 1977 and operational evaluation in February 1978. Production release was in May 1979, the initial contract being awarded in July 1979 (and the last in February 1987). Some Mod 5s were manufactured for the Dutch and British navies, and Mitsubishi manufactures this torpedo under license in Japan (coproduction approved July 1982).

About 1986 the U.S. Navy's reported objective was a total of 5500 Mk 46-5 and 3000 Mk 46-4 torpedoes. Total production, for FY80 and previous years, was 11,646 torpedoes. Purchases in later years were: 253 in each of FY81 and FY82, 440 in FY83, 1200 in FY84, 1565 in FY85, and then 500 each in FY86 and FY87. These figures do not include the torpedoes used in CAPTOR mines and may not include some export torpedoes. In FY87 the price per torpedo was \$195,322. In 1985 the navy proposed to end production of Mk 46 in FY88 (500 torpedoes). At that time procurement of 1521 had been scheduled for FY86, and that figure was cut to 500.

In 1987 it was reported that total Mk 46 production, including export weapons, had been over 17,000. That figure included about 1252 Mod 0 of 1963-65 (by Aerojet) and about 9200 Mod 1 manufactured 1965-69 by Honeywell. As of July 1989, Honeywell had delivered 20,000 Mk 46 torpedoes for the U.S. Navy and 23 foreign navies. Honeywell became second-source supplier in July 1965 and became single-source supplier in 1969. The 5000th Mod 1 was delivered in March 1967. The first NEARTIP contract, for 2706 kits, was awarded in February 1978. Contracts for another 5140 kits were let in 1979-83, and production was continuing as of 1989.

It was announced in November 1988 that Brazil was buying Mk 46 Mod 5 torpedoes for delivery in 1988 and 1989, and kits to update existing Brazilian Mk 46 Mod 2s. Mk 46 is currently operated by 23 navies.

◆ Mk 48/ADCAP

Dimensions: 21 × 230 in **Weight:** 3480 lb

Speed/Range: estimated 55 kt/35,000 yd

Power Plant: 500-HP Otto fuel swash-plate engine

Mk 48 began as a development of the RETORC II (Research Torpedo Re-Configuration) research program, which had been underway since 1956. Development characteristics for a new torpedo (at that time designated EX-10) were set in 1960, and tenders requested in May 1962. A project-definition contract was awarded to Westinghouse in 1964, with Sundstrand providing propulsion and Clevite (later renamed Gould) the acoustics; Clevite also received a backup contract for a separate homing system. At that time the existing Mk 37 was credited with only 10% effectiveness against a 20-kt submarine. The proposed Mk 48 was credited with 40% effectiveness against a 35-kt submarine, and work was accelerated after system tests on board the submarine *Permit* in the Pacific in 1964. In 1967-68 further contracts were awarded to modify the basic torpedo for antiship as well as antisubmarine use, the single-purpose Mk 47 antiship torpedo project having been abandoned. Mk 48 entered service in 1971.

Mk 48 is the current standard U.S. heavy torpedo. Mod 0 was a single-purpose antisubmarine torpedo, developed at high priority after 1964 tests showed very clearly that the existing Mk 37 could not successfully engage modern nuclear submarines. Mod 1 added antiship capability. Mod 1 and Mod 2 were competitive prototypes; Mod 2 (rejected) had a turbine engine, Mod 1 a swash-plate piston engine using Otto II (nitrogen ester with oxidant) fuel. Mk 48 differs from many other torpedoes in using a pump jet rather than conventional propellers for propulsion, a choice presumably made to provide very high speed without so much noise that the weapon would be unable to home, or that the target would be alerted soon enough to escape easily. Published illustrations of the new Mk 50, which is also very fast, show a similar pump jet.

The performance listed here is based on congressional testimony (in the 1970s) to the effect that Mk 48 has a range of 20 miles (presumably statute, not nautical) at "nearly twice the speed of Mk 37." Published figures more than a decade old suggest an acquisition range of 4000 yd (compared to 1000 for Mk 37) and a diving depth of 2500 ft. Mk 48 has also been described officially as the only U.S. torpedo capable of reaching the Alfa's depth, reported as 800 m [2624 ft]. It was reported in the 1980s that Mk 48's search speed was 40 kt, so presumably, the higher maximum speed given above is a run-out and attack speed.

Aside from the active and passive homing modes, there is a nonacoustic mode, presumably a straight or pattern-running

shot at a surface target, the only intelligent element of the torpedo being its fuze. Numerous published photographs showing Mk 48s blowing substantial ex-warships in half strongly suggest that the torpedo uses a standoff (proximity) fuze for under-the-keel explosion.

Mk 48's design emphasizes maintainability, with unit replacements (functional item replacements) to minimize repair time.

Mod 3 (1977) adds a 2-way (rather than 1-way) wire link (TELCOM), allowing the torpedo operator to exploit the torpedo's own sonar. TELCOM transmits 14 torpedo and target parameters once each second.

Mod 4 incorporates TELCOM as well as a fire-and-forget mode. Mod 4 was a transitional step toward ADCAP, and as of 1984 the U.S. Navy planned to buy 144 Mod 4s in both FY85 and FY86, ending procurement in FY86, and to begin production of all-up ADCAPs in FY87. Costing studies led to the decision to end Mod 4's production with 108 torpedoes in FY85 and to begin ADCAP production that year with 30 torpedoes (with 123 in FY86 and 280 in FY87). However, Congress disagreed, and ADCAP's production was actually slowed, so many conversion kits were procured instead.

Mod 5, a modification kit for existing Mk 48s, is an interim step toward the new ADCAP version.

ADCAP (Advanced Capability) is an extensively modified version capable of greater speed and endurance and incorporating a new homing device. When ADCAP was first developed, there was speculation that it should have received a new Mk number. It appears that Mk 49 was reserved for this purpose but that the Mk 48 ADCAP designator was preferred for political reasons.

The ADCAP program was inspired by tests that showed that the basic Mk 48 structure could operate at the depths achieved by the new Soviet Alfa-class submarine, and that targets could be recognized at the necessarily high torpedo speeds involved. The forward-looking sonar had adequate vertical coverage. The modifications involved were made in the Mod 4 version of the torpedo.

ADCAP provides sustained long acquisition range; it minimizes the effects of the submarine's operating envelope (speed and depth) and countermeasures; it minimizes tactical constraints imposed on the launching submarine (because of its higher speed and maneuverability); and it has increased antiship capability. Compared to the existing Mk 48, it has a new nose, including the transducer, the beam-former, and the signal processor. The new sonar is electronically steered, so the torpedo

Mk 48 torpedo, showing the pump jet. (Westinghouse)

need not maneuver nor lose as much net forward speed as its predecessors as it approaches a target. Although ADCAP has the same swash-plate engine as its predecessor, the fuel rate is increased (and more allowance is made for speed variation). The torpedo carries more fuel, in space made available by a more compact computer.

The improvements were sufficiently extensive that a new designation, EX 49 (later Mk 49), was assigned in 1977. The development proposal for the new torpedo was issued in March 1975. The Mk 49 designation was formally assigned in 1984, but it was never used. Presumably, the use of the Mk 48 ADCAP designation was intended to justify a simplified development process, just as current electronic equipment often retains earlier designations despite radical improvements.

In 1981, in connection with the competition for the British heavy torpedo, ADCAP's speed was reported as 60+ kt. As a rule of thumb, a torpedo should be about 50% faster than its target. Thus the torpedo speed associated with a 42-kt Alfa-class submarine would be 63 kt (ADCAP has often been associated with the requirement to attack Alfas).

The ADCAP Operational Requirement was issued in 1975, an RFP following in November 1978. The program was accelerated in September 1979 in view of the demonstrated characteristics of the Alfa-class submarine. ADCAP went into advanced development in October 1979. Hughes received the contract to develop the torpedo's digital guidance and control electronics in August 1979. The first test run was made on the Canadian NANOSE range early in 1982, using an ADCAP inertial system. At that time it appeared that about 240 runs would be needed, continuing into 1983-84. However, development was protracted. In 1985 it was decided to accelerate production. The 1985 Five Year Defense Plan called for 1890 ADCAPs, and 123 were included in the FY86 budget. Production began in 1985. At that time the reported navy objective was 4659 Mk 48 torpedoes, of which 4000 had been funded through FY87; the cost per Mk 48 was then \$2,239,515. The

(Below) Mk 48 ADCAP's guidance section. (Hughes)

(a)

(b)

Mk 48 Mod 4 (a) and ADCAP (b). ADCAP has much greater fuel stowage, made possible by shrinking the size of the computer between the warhead and the fuel tank. (Westinghouse)

currently stated objective for ADCAP modification kits (for Mk 48 Mod 5) is 1062 (March 1988).

Production of Mk 48: 3059 were procured through 1980, then 144 in FY80, and the same number in each of FY81–84. Mk 48 procurement ended in FY85 (108 that year). Mk 48 has been exported to the Australian, Canadian, and Dutch navies; reported numbers are, respectively, 127 (1979), 48 (1985), and 100 (1980). The first near-term upgrade Mk 48 Mod 4 was delivered to the U.S. Navy in December 1980. ADCAP technical evaluation began in August 1986. ADCAP procurement: 30 in FY85, 123 FY86, 50 FY87, 100 FY88, 320 FY89, 260 (cut from 320 requested) FY90, 240 (requested) FY91 (cut from 320 planned). FY91 unit cost is estimated at \$1.46 million. The FY92–93 budget submission (in February 1991) called for 108 torpedoes in each year, at a unit cost of \$2.04 million (FY92).

The current research program includes a fiber-optically guided Mk 48 ADCAP, which is to transition to advanced development in FY91.

Westinghouse bought Gould's Mk 48 production division in January 1988. The first ADCAP warshot (which sank a decommissioned destroyer) was reported in July 1988.

The Westinghouse version was powered by a Sundstrand turbine; Gould's, by Gould's own swash-plate engine. Reportedly, the turbine was much quieter, but Gould's engine was more efficient, particularly at maximum depth, where the combustion products are ejected against considerable back pressure. Torpedo noise was not the determining factor at this time, as the United States enjoyed both the sonar and the weapons advantage, and Gould was chosen. The Sundstrand engine was adapted for the British Spearfish. The engine's power was doubled, and the thermal efficiency of the Otto fuel enhanced by 40% by mixing with an oxidant, HAP (hydroxylamine perchlorate).

In March 1990 it was reported that by 1993–94 the navy hoped to introduce a Quiet ADCAP, which would use a closed-cycle ADCAP propulsion system (CCAPS), noise damping, and machinery isolation. At the time, it was reported that a current

ADCAP running at full speed produced noise levels equivalent to a U.S. nuclear attack submarine running at full speed. Two phases were planned. The first was to increase speed (presumably, quiet search rather than noisy run-out speed) from 40 to 65 kt; the second was to increase this speed to 75 kt without any increase in radiated noise and with an increase in range from 22,000 to 30,000 yd (all of these figures are what was reported in the press at the time). Other proposed ADCAP improvements are improvements in terminal homing, in countermeasures resistance, and in guidance and control for Arctic operations.

As of 1988, there is a U.S.-U.K. MoU on cooperative development of the next-generation heavy torpedo, to replace both ADCAP and Spearfish.

◆ Mk 50 Barracuda

Dimensions: 12.75 × 111.5 in (total length may grow to 115.5 in)
Weight: 771.2 lb **Warhead:** shaped charge
Power Plant: closed-cycle thermal (SCEPS)

Mk 50 was developed specifically to counter Soviet Alfa-class submarines and future deep-divers, which were beyond the reach of the existing lightweight torpedoes. Mk 50 will be carried by aircraft, fired from surface ships' torpedo tubes, and fitted as the warhead of the Sea Lance and Vertically Launched ASROC missiles. The 1986 decision to develop Sea Lance primarily as a conventionally armed missile has been read as an indication of the success of the Mk 50 warhead against simulated submarine targets; proponents of the alternative nuclear version have suggested that no lightweight torpedo can reliably attack a large double-hulled submarine.

No performance or homing details have been released. However, if Alfa is credited with a speed of over 40 kt, then the usual requirement for a 50% speed margin equates to a maximum Mk 50 speed of about 60–63 kt. Homing is both passive and active (FM active), and it was officially stated in 1987 that Mk 50 homes at twice the range of Mk 46. An official ASW history written in the late 1970s but declassified in 1990 gives the design requirements (ca. 1975, before the competition) as a range of 15,000 yd at 55 kt, with an acquisition range of 3000 yd.

The unusual thermal power plant, SCEPS (Stored Chemical Energy Power System), incorporates a block of solid lithium and a tank of sulfur hexafluoride. When the torpedo is fired, electric squibs melt the lithium, and it is allowed to react with the sulfur hexafluoride, creating both heat and a solid ash. The heat in turn is used to produce the steam that propels the torpedo. This system was adopted because the combustion product, the ash, has less volume than the reactants, and so does not have to be dumped outside the torpedo during its run. The torpedo's engine, therefore, does not have to fight increasing water pressure as the weapon dives toward its target. Garrett, which developed the system, says that it is actually easier to produce than the Otto-fuel power plant of a Mk 46.

Development began with a technical-assessment phase (February 1972–September 1978). The first series of competitors (Gould/Hughes, Westinghouse, McDonnell Douglas/Raytheon, and Honeywell/Garrett) began work in 1978, following a 1975 technology assessment. Two winners were selected in 1979 for a swim-off: McDonnell Douglas/Raytheon and Honeywell/Gar-

(Below) Mk 50 Barracuda torpedo: the exercise version. (Honeywell)

rett. The Honeywell/Garrett design won in 1981, and full-scale engineering development began in 1983.

The McDonnell Douglas design, Mk 51, reportedly used Raytheon's side-looking linear or flank sonar arrays and may, therefore, have incorporated more of a passive capability. Mk 51 also had a GE silver-oxide electric battery. Published drawings of the Mk 50's nose show clearly that it has only a forward-looking sonar array.

As of 1988, the reported objective for production of Mk 50s was 7743 torpedoes plus 160 for research and testing. Estimated unit cost is \$250,000, compared to \$180,000 for Mk 46 at a high production rate.

Approval for low-rate production was granted in 1989, based on success in initial tests. Operational evaluation was to be completed by September 1990. Procurement: 39 in FY87, 16 in FY88, 140 in FY89, 200 in FY90. As of January 1990, the request for FY91 was 265 Mk 50, at a total cost estimated at \$328.3 million, or \$1.24 million each (but that figure is probably misleading). The FY92-93 budget (in February 1991) called for 246 in FY92 and 264 in FY93, at a unit cost of \$1.06 million (FY92).

In March 1990 it was reported that current plans called for a new advanced-development version of SCEPS, to increase the maximum speed from 55 to 70 kt (the range from 14 to 18 kyd). These figures are what was reported in the press in March 1990.

Two new warhead concepts are currently under consideration, one described as a trumpet (presumably a shaped charge), and the other (higher-risk) approach requiring additional torpedo volume. This is probably the follow-through warhead described officially as part of the Balanced Technology Initiative (BTI). A follow-through or tandem warhead, which has also been proposed for the army's TOW antitank missile, uses 1 charge to breach the target and then fires a second warhead through the hole. The idea is not new: early in this century the U.S. Navy (and probably other navies) experimented with a torpedo gun, a torpedo that fired a shell through the underwater hole it made in a target. Current research also includes an attempt to reduce the physical size of torpedo electronics and propulsion (while improving performance) to allow for a larger warhead; total torpedo volume is limited by factors such as the dimensions of the S-3's bomb bay.

◆ Surface Torpedo

An attempt to buy a lower-cost single-purpose (antiship) torpedo ended in 1987, even though Whitehead won the competition with a modified A-184. See the previous edition for details. The designations EX-52 and EX-53 were reserved for 2 alternative heavy antisurface torpedoes, but they were not used.

◆ Lockheed Lightweight Torpedo/LENS

Since the early 1980s Lockheed has developed a range of lightweight underwater vehicles. One version was offered to Sweden to meet the Angler requirement (see the Swedish torpedo section, above); it weighed about 160 lb. It was successfully tested against tethered and bottom targets in the Baltic in 1986. The torpedo-shaped vehicle is modular, consisting of a sensor head; a basic body containing the warhead, batteries, and microprocessor control system; a motor; and a guidance section (for either free-swimming operation or for wire or fiber-optic link guidance). Lockheed offers 3 sensors: a horizontal homer (sonar), a horizontal and vertical homer (sonar), and a television with or without the sonar. The vehicle can carry either a bulk or a shaped charge. The 2 alternative power plants are 6 and 15 kt DC motors. The company designation, LENS (Lockheed Expendable Neutralization System), straddles the border between ASW and mine countermeasures. Lockheed currently offers or plans a mine-warfare LENS, a TV LENS (using fiber optics to communicate with the operator), an ASW LENS (20 kt), and a hovering surveillance LENS.

The basic vehicle is 20 cm [8 in] in diameter; the faster ASW LENS is slightly larger. Lockheed's original mine-warfare system used a 1.6-m [63.0-in], 44-kg vehicle carrying a 17-kg payload at up to 6 kt, in water depths of up to 200 m. Endurance

Lockheed LENS vehicles showing alternative sensor heads. The 2-sensor vehicle was successfully demonstrated against tethered and bottom targets in the Baltic late in 1986. It shows the folding arms that carry underwater lights. The other vehicle has a cable-catcher above its single sonar. (Lockheed)

is 30 min at 4 kt with a nickel-cadmium battery. This is essentially an antitorpedo mine, brought near the target by a guidance wire (up to 2 km long), which then uses its own active sonar (30-m range) to home onto the mine. The vehicle is tracked by the ship's minehunting sonar (it carries a sonar blip enhancer).

This is probably the vehicle tested by the Royal Swedish Navy for the Angler requirement.

The next stage was a larger vehicle (1.8 m [70.9 in] long, total weight 53 kg with a 20-kg payload), with the same speed and endurance characteristics, but carrying both a sonar and an underwater color television (range 1-20 m, depending on water conditions). The color television has a much wider FOV, and the vehicle carries a pair of high-intensity underwater lights on folding outriggers. This version is much more sophisticated: the vehicle sends back its sonar and television video via a fiber-optic link. The operator console now displays the vehicle's image of the object it is investigating. It also shows vehicle control parameters and vehicle status. The vehicle carries an altitude sonar by means of which it can fly above the bottom, and an optional nose maneuvering unit allows it to stop and point in a direction of interest. Payload weight can be traded off against an additional battery section, for greater endurance.

The undersea surveillance system is a variation on this theme. The nose of the vehicle carries the video camera, the short-range sonar, and an altitude-keeping sonar (as in the mine attacker above). The body carries a pair of high-intensity lights as well as an 80C86-based microprocessor (which deals with the 80186-based single-board computer in the operator console). As in the other versions, the vehicle carries a sonar beacon, and it sends back its video via a fiber-optic link. Length is 2 m, payload is 20 kg (weight 60 kg), and maximum speed is 7 kt (endurance, using a nickel-cadmium battery, is 20 min at 4 kt).

In this case surveillance means investigating suspicious bottom contacts (as would be the case in Sweden) rather than any wide-area mission as it would be understood elsewhere.

The ASW attack vehicle shares the shape of the other versions, but it is larger (25 × 215 cm [10 in × 84.6 in], 100 kg with a 20-kg warhead), faster (20 kt), and has greater endurance (80 min at a 4-kt search speed, 20 kt for 1 min at attack speed), because it uses a silver-zinc battery rather than the earlier nickel-cadmium. Its nose sonar is much more powerful (acquisition range in active mode, 300 m; vertical extent of sonar coverage, 30–100 m). The sonar uses a horizontal and vertical split beam for more effective homing. The weapon can function in fire-and-forget mode, or it can be wire guided (control range is 4 km), using a fiber-optic link to display its sonar picture (both raw and processed video) to an operator. Because most of the intelligence of the system is in the operator's console, the weapon itself can be relatively inexpensive.

Lockheed describes this as a mission-abort weapon, not quite large enough actually to kill a target. Presumably, it is the basis for the Lockheed contribution to 1 of the NLCAW proposals. A Lockheed sketch shows its large effective area compared to a depth bomb. Critical vehicle components were tested in the Baltic in 1986, i.e., were part of the Lockheed Angler proposal, and the homing mechanism was verified in shallow water in tests at the Nanoose range against the ex-USS *Menhaden*. This device can be dropped by an airplane or a surface ship or fired out of a conventional larger-diameter submarine torpedo tube.

TORPEDO LAUNCHERS

◆ Mk 14

These quintuple 21-in tubes survive on board a few *Fletcher*-class destroyers in foreign service. Total weight, including 5 torpedoes Mk 15, is 43,100 lb. With the tubes loaded (spoons up), working radius is 152.64 in. Torpedoes are mechanically set (the tube cannot, therefore, be used with modern homing weapons) and are mechanically started; they are ejected using black powder, at an initial velocity of 55 ft/sec. Each quintuple tube is served by a gyro setter, a trainer, and a tube captain.

◆ Mk 25

Mk 25 survives only on board the Spanish *Baleares*-class frigates and the destroyer *Marques de la Ensenada*, which use it to launch Mk 37 torpedoes. It was installed on board a few U.S. destroyers and frigates but was quickly removed. Mk 25 was designed to fire both homing torpedoes (originally Mk 35, later Mk 37) and fast straight-runners (Mk 16). Torpedoes are launched by air pressure, and the tube has provision for electrical torpedo setting. Barrel length is 247 in (overall length, with the muzzle door open, is 279 in), and total weight is 1900 lb/barrel.

◆ Mk 32

Mk 32 is the standard lightweight torpedo (12.75-in) launcher on board numerous U.S. and foreign frigates, destroyers, and cruisers. Mk 32 succeeded torpedo-launching system Mk 2, a catapult ("poor boy") for the Mk 32 torpedo, whose oversized fins precluded tube launch. Mk 2 could also be used to launch the much heavier Mk 37 torpedo. It is now extinct in the U.S. Navy, and probably also abroad.

Mk 32 is normally fired remotely (electrically), but all versions prior to Mod 15 have provision for local emergency firing. Mod 15 lacks any such provision. Torpedoes are ejected by air. Trainable tubes have interlocks that prevent firing when they are not trained outboard. In addition, Mods 9 and 15 have interlocks requiring that the muzzle doors be open before the torpedoes can be fired.

These launchers are manufactured abroad under license, e.g., by Plessey.

Versions of Mk 32:

Mod 0 Initial version, a fiberglass-barrel launcher for torpedoes Mk 44, 43 Mod 1, and 43 Mod 2. Total weight was 2280 lb.

Training circle: 70.875 in at muzzle end, 75.625 in at breech end; the tube could train through 190 deg. Overall height is 52.688 in. A Mk 44 torpedo emerged from the tube at 40–65 ft/sec. This nomenclature was assigned in May 1958. ORDALT 4342A (December 1963) modified Mods 0, 1, and 2 to permit remote presetting and firing of Mk 44 and 46 torpedoes. Mods 0 and 1 were converted to Mod 6 on ships with Mk 102, 105, or 111 FCSs. These Mods were converted to Mod 8 on ships with Mk 114 FCSs.

Mod 1 Alternative to Mod 0 with air-pressure charging line for vessels without HP-air compressor systems (1958).

Mod 2 Value-engineered Mod 0 with new training gear, barrels, breech mechanism, and securing mechanism and a new method of storing the charging line. ORDALT 4342A (December 1963) converted Mod 2 to Mod 5 on ships with FCSs Mk 102, 105, and 111, and to Mod 7 on ships with FCS Mk 114.

Mod 3 Single-barrel fixed version for the experimental hydrofoil patrol boat *High Point* (770 lb, 1959).

Mod 4 Mod 0 or 1 modified by ORDALT 4342 to be compatible with control panel Mk 264, to permit remote changes to preset functions of Mk 44 or 46 torpedoes up to the moment of firing. Mk 264 selects and sets any 1 of 6 torpedoes in 2 tubes. The pneumatically operated torpedo-plug pullers extract the electrical plugs from the torpedoes during the firing cycle prior to ejection. The torpedo-squib fire switch automatically unlatches the torpedo's gyro during the emergency-manual-firing cycle (1961).

Mod 5 Modified Mod 2, with a second junction box to distribute electrical preset data from the Mk 264 Mod 1 panel to any of its 3 torpedoes. It has remote (by Firing Panel Mk 264) rather than local electrical firing and an air-operated plug puller. Heaters are built into the tubes. This designation dates from June 1961. This version can also be controlled by Firing Panel Mk 309. Weights: 2230 lb empty, 3110 lb with Mk 44 torpedoes, 3754 lb with Mk 46, 4450 lb with Mk 50. Some Mod 7s were converted to Mod 5 under ORDALT 6720 (September 1970) for ships with FCS Mk 105 and 111. ORDALT 7020 (November 1970) modified Mods 5–9 to indicate the type of weapon loaded without visual check. It prevented inadvertent firing of the weapon when the torpedo selected was not the same as the torpedo loaded. ORDALT 7658 (January 1971) to Mods 5–9 was interim deletion of the no-run-out presetting capability when launching a torpedo from the lower barrel. A Mk 46 launched in this mode was likely to acquire the wake of the firing ship and would probably attack it.

Mod 6 Mod 0 or 1 tube converted by ORDALT 4342 to permit remote changes to torpedo presets (analogous to Mod 4) for ships with FCSs Mk 102, 105, or 111. A second junction box is added for distribution of presetting circuitry. The associated firing

A Mk 32 triple tube on board the nuclear cruiser *Mississippi*, June 1988. (S. Terzibaschitsch)

Panel is Mk 264 Mod 1 (1961). Some Mod 8s were converted to this version (ORDALT 6720, September 1970).

Mod 7 Similar to Mk 5, but internal wiring is modified to connect to Attack Console Mk 53, so the tubes can be controlled by FCS Mk 114 or Mk 116.

Mod 8 Modified Mod 0 or Mod 1 for ships with FCS Mk 114, to permit remote setting and firing of Mk 44 and 46 torpedoes. Conversion entails installation of a second junction box, 3 pneumatic plug pullers, and 3 barrel-ready and torpedo-squib fire switches. Torpedo input-setting and tube-firing signals are transmitted from the Mk 114 system via the second junction box. The plug pullers extract the electrical plugs during the firing cycle. Barrel-ready switches signal the control center that barrel and torpedo are ready to fire. Squib-fire switches unlock the torpedo gyro during manual emergency fire (1961).

Mod 9 Twin (rather than triple) launcher, fixed in train, for *Knox*-class frigates. It is otherwise similar to Mods 7 and 8 and works with Attack Console Mk 53 of FCS Mk 114. With an insert, it can fire Mk 43 torpedoes. This is the version used in the Canadian "City"-class frigates. Weights: 2010 lb empty, 2890 lb with Mk 44 torpedoes, 3026 lb with Mk 46, 3710 lb with Mk 50.

Mod 10 Single fixed tube. Weights: 602 lb empty, 1050 lb with Mk 44, 1110 lb with Mk 46, and 1342 lb with Mk 50 torpedoes. This tube was designed for control by Control Panel Mk 264. It is similar to Mod 3 except for the remote-control features. It can fire Mk 46 Mod 1 torpedoes (1967).

Mod 11 Single fixed tube, similar to Mod 10 but with safe/ready remote features added. Weights: 650 lb empty, 1100 lb with Mk 44, 1160 lb with Mk 46, 1390 lb with Mk 50 torpedoes. This tube was designed for control by Control Panel Mk 264 or Mk 309 (1967).

Mod 12 Single fixed tube on 2 flexible (antivibration) mounts, similar to Mods 10/11 but with a power-actuated muzzle-door mechanism (1967).

Mod 13 Triple version intended for the experimental Canadian hydrofoil *Bras d'Or*, to fire Mk 46 Mod 0 and Mod 1 torpedoes (1966). It was fixed, with the 2 lower tubes splayed 34 deg outward.

Mod 14 Version for the *Spruance* class, mounted in a deckhouse. It is similar to Mod 7 but with faster response: the motorized train gear slews the launcher to a 45-deg angle for firing, and there is a remote barrel-readying feature. Torpedoes are preset and remotely fired, and the tube is trained by Torpedo Setting Panel Mk 331 (of FCS Mk 116) or Weapons-Control Panel Mk 329; there is also a local bulkhead-mounted control box. Weights: 2380 lb empty, 3260 lb with Mk 44, 3904 lb with Mk 46, 4600 lb with Mk 50 torpedoes.

Mod 15 Version for the *Arleigh Burke* class, weatherdeck-mounted. It is intended not to be manned. It is similar to Mod 7 but with remote barrel reading, a positive weapons-away indication for each barrel, and heated and remotely controlled muzzle doors.

Mod 16 Version for the SSTD program, to launch a modified lightweight torpedo as an antitorpedo weapon. Similar to Mod 15 but with different muzzle doors and modified control boxes. It can fire Mk 46 and Mk 50 torpedoes and is similar to Mod 5. This version is to be installed on board selected major combatant ships. The nomenclature was assigned in November 1989.

Mod 17 Version of Mod 5 (ORDALT 15713) modified to fire Mk 50 torpedoes (retains Mk 46 capability); for *Perry* class, WHEC 715 coast guard cutters, the *Long Beach*, and the *Bainbridge*. This nomenclature was assigned in December 1989.

Mod 18 Conversion of Mod 7 (ORDALT 15713) for *Leahy*-, *Belknap*-, and *Virginia*-class cruisers, to fire Mk 50 as well as Mk 46 torpedoes.

◆ Submarine Torpedo Tubes

Pre-World War II pneumatic tubes survive only on board former U.S. Guppy-type submarines in foreign service. These tubes (Mks 32 and 34 bow tubes, Mks 33 and 35 stern tubes) were modified postwar for electrical torpedo setting. Launching velocity varied with conditions but was typically 50–60 ft/sec. Maximum air pressure was 600 psi. Barrel lengths: bow tubes, 251 in, stern tubes 276 in. Because the tubes are pneumatic, maximum firing depth is 200 ft.

Work on a hydraulic torpedo tube began in 1944, and an experimental full-scale tube, using a motor-driven centrifugal pump, was built and tested. It achieved 15 ft/sec, and tests showed that 1900 HP would be required to achieve 40 ft/sec. In 1948 Electric Boat proposed a new design using an air-actuated piston pump instead of the centrifugal pump, and a prototype was tested on board the USS *Becuna* (SS 319). It was first operational in the *Tang* class. For each bank of 3 tubes, there is 1 ejection pump (water cylinder, air cylinder, and piston). Each stroke ejects 1 torpedo.

The initial postwar hydraulic bow tubes (Mks 43 and 45) used a 1500-psi impulse and achieved an initial velocity of 32 ft/sec. Torpedoes were all electrically set and started. Typically, a submarine had 1 hydraulic pump for the 3 tubes on each side. Barrel length was 252 in. The corresponding stern tubes (Mks 44 and 46) were swim-out tubes intended specifically for ASW torpedoes (initially Mk 27); typical swim-out speed was 10 ft/sec. Barrel length was 142 in, corresponding to the half-size adopted for such weapons.

The figures for Mks 43 and 45 are typical of later practice, although the tubes themselves have long been superseded. The main difference is somewhat greater impulse power; all current tubes are hydraulic so that they can be fired at all depths.

Current types:

Mk 63 *Permit* and *Sturgeon* classes, designed for increased depth, otherwise similar to earlier types. In contrast to previous types, these tubes were designed for operation from a control panel.

Mk 64 *Tullibee* tube, the first U.S. tube mounted abaft the bow, angled outboard.

Mk 65 Ballistic-missile-submarine tubes.

Mk 66 Experimental external 30-in tube on the deep-diving auxiliary submarine *Dolphin*.

Mk 67 *Los Angeles* class.

Mk 68 *Ohio* class.

Mk 69 30-in tube planned for the new *Seawolf* class. It will be able to fire both 21- and 30-in weapons and is a totally new design. The prototype is being tested on board the USS *Memphis*.

UNGUIDED WEAPONS (MORTARS AND DEPTH CHARGES)

CHILE

Cardoen, the Chilean explosives manufacturer, produces a fast-sinking depth charge, AS-228, externally similar to the U.S. "tear drop" of World War II. Depth of burst can be set at any of 19 figures between 100 and 1600 ft.

Cardoen also manufactures miniature antiodiver depth charges that can be set to explode between 4 and 12 m.

CHINA (PRC)

◆ 250-mm Rocket Launcher

Although similar in concept to Soviet RBUs, this weapon seems to differ in detail. As employed on board *Luta*-class destroyers, it has 12 tubes: an outer shallow horseshoe layer of 7, with 5 inside (2 on each side, 1 in the middle). The mount elevates and trains. A 5-tube version (the Soviet RBU-1200) is carried by

Jianghu-, *Jiangdong*-, and *Jiangnan*-class frigates. The tubes resemble those of the Soviet RBU-1200 (see entry below), and this weapon is probably a modification of the Chinese version of the earlier Soviet system.

This weapon became operational in 1972. The Chinese commercial designation is EDS-25A.

FRANCE

◆ 305-mm Mortar

This 4-barrel automatic-loading mount is found only on the *Commandant Rivière* class (French and Portuguese navies). Its ASW projectile weighs 230 kg and has a range of 400–2750 m [507 lb, 440–3000 yd], and there is also a 100-kg [220-lb] shore-bombardment round with a 6000-m [6600-yd] range. Usually 4 illuminating rocket rails are mounted on the sides of the mount.

The ASW round is time-delay fuzed, the fuze being set inside the launch tube. The barrels fire at the rate of 1 rnd/sec, re-loading through their muzzles (continuous firing rate is one 4-rnd salvo every 25 sec). Rounds are stowed in 4 carousels, 1 feeding each of the 4 hoists.

Typical weights are 22.2 tons (metric) for the mortar, 18.75 tons for 72 rnds of ammunition, and 4.7 tons of fittings.

Control is by a DUBA 3 attack sonar.

305-mm ASW mortar between bridge and forward gun, *Commandant Rivière*. The mortar is in the loading position. (Stefan Terzibaschitsch)

ITALY

◆ Menon Mortar (K 113)

This single-barrel automatic-loading 305-mm [12-in] mortar is fired at a fixed 45-deg elevation. Range is varied (400–900 m [440–980 yd]) by adjusting gas vent valves on 3 powder chambers. The depth charge weighs 160 kg [353 lb]. The barrel, which is 4.6 m [181 in] long, loads automatically from a 7-rnd cylinder, firing a 7-rnd pattern. An earlier 3-barrel version, Lancia Bas, is no longer in service. It fired a 21-rnd pattern in 70 sec, covering an area of about 80 × 180 yd.

There is no associated depth-determining sonar; ships carrying these mortars carry scanning sonars.

The Italian frigate *Carlo Margottini* shows a single-barrel Menon (K 113) ASW mortar between her No. 2 3-in gun and her bridge. The guns are predecessors of the OTO-Melara 76-mm/62. The fire-control radar is RTN-10X, and the air-search set is SPS-12; above it is SPQ-2 (at the masthead). (U.S. Naval Institute)

◆ MS 500

Misar's 500-lb ASW bomb/mine was designed specifically for the Atlantic maritime-patrol aircraft, which Italy operates. Although Misar describes it as a bottom mine, the company also notes that it is unusual in being equipped with an acoustic proximity fuze that detonates the bomb at the closest trajectory point to its target, so it requires no depth presetting.

NORWAY

◆ Terne III

This rocket-fired depth charge was introduced about 1960 in its Mk 3 version for the *Oslo*-class frigates and the *Sleipner*-class corvettes. Terne III is now in a Mk 8/10 version.

The system was developed by the Norwegian Defense Research Establishment with assistance from the United States under the Mutual Weapons Development Program. The system uses a stabilized searchlight sonar to search for, detect, and track the target in depth. As fitted to U.S. ships, Terne III was triggered by the SQS-31 or -32 search sonar. In this application the sonar had a maximum depth of 1000 ft (maximum depression angle 35 deg). The U.S. designation for the Terne rocket was Rocket Thrown Depth Charge Mk 3. The launcher was designated Mk 117 Mod 0. The typical salvo pattern consists of weapons 20 yd apart in a line perpendicular to the target's course. Fuzing modes are time and proximity, the latter using a sonic doppler signal to detonate 20 ft from the target (or upon

The Norwegian frigate *Narvik* shows her prominent enclosed Terne III launcher between her forward twin 3-in/50 gun and her bridge. The radar above her bridge is a French DRBV 22, with a Signaal WM-24 above. The radar aft is a Mk 91 controlling NATO Sea Sparrow missiles. (U.S. Naval Institute)

The Terne launcher. (Kongsberg)

Typical Terne reloading arrangement. (Kongsberg)

contact). In the time mode, the depth charge explodes 0.3 sec after water entry.

For the Mk 3 version, air range at 70 deg F is min 400 and max 920 yd. Corresponding air-flight time is, respectively, 18.2/13.3 sec. Depth limits are 50 and 700 ft. In U.S. service Terne was part of ASW Weapons System Mk 1. For Mk 8/10, range is 400–5000 m; total weight is 120 kg (explosive charge equivalent to 70 kg); dimensions are 21 cm × 2 m. The launcher has 6 barrels and elevates to 47–77 deg to fire. It can be reloaded in 30 sec, and 6 salvos are available in ready-use stowage. The deck opening, which is covered by 2 weather hoods, is 3.6 × 5.0 m.

SWEDEN

◆ Bofors 375-mm Rocket Launcher

This weapon is widely used both in the original 4-barrel and in a later 2-barrel version. However, this launcher is no longer used by the Swedish navy, that service having abandoned the use of large surface ships.

The usual installation includes a power-driven 4-barrel launcher vertically (for minimum ship impact) power-loaded from below. Initially, Bofors offered only the 4-tube weapon with either long or short hoist, but in 1967 the company added 2 types of 2-barrel launchers.

The associated ERIKA-type ASW rocket has a maximum velocity of 205 m/sec [672 ft/sec]. Range (300–3600 m [330–3900 yd]) is adjusted by selection of 1 of 4 types of rocket (for varying velocity) and by elevation. Rockets have 2 concentric (inner and outer) motors, and velocity can be further varied by firing 1 or both. Depth of burst is set either by time (STIDR) or by acoustic proximity (ZAMBO) fuze; there is also a combined impact (direct acting) and time fuze (STIDAR). The lethal radius of each round is about 15 m [16 yd]. Rockets weigh 250 kg [550 lb]; they vary in bursting charge. Types are M/50, Type E (for ERIKA), and Type F (for Flora). The mounting trains and elevates at 18 deg/sec. Elevation limits are +15 and +90 deg. Rocket characteristics are as shown below.

Bofors 375-mm Rocket Launcher

	ROCKET TYPES			
	M/50	Type E	Type F	Type N
Weight (charge)	100 kg [220 lb]	107 kg [236 lb]	107 kg ^a [236 lb]	80 kg ^b [176 lb]
Min Range	370 m [405 yd]	670 m [732 yd]	1400 m [1530 yd]	1530 m [1670 yd]
Max Range	875 m [957 yd]	1660 m [1815 yd]	2230 m [2439 yd]	3600 m [3940 yd]
Terminal Sinking Speed	10.9 m/sec [35.8 ft/sec]		10.2 m/sec [33.5 ft/sec]	9.2 m/sec [30.1 ft/sec]

^a Total weight of Type F is 242 kg [533 lb].

^b Burst weight. Total weight of Type N is 230 kg [507 lb].

The French version of the Bofors 375-mm rocket launcher. The flare-launching racks are alongside the rocket tubes. The guns are twin 57-mm/60s, also a French version of a Bofors original. (L. van Ginderen)

The long-hoist 4-rocket launcher weighs 7.3 tons exclusive of flame guard, and normally 8 rockets (2 more salvos) are carried on the rocket table below. Rockets can be fired at intervals of 1 sec, and it takes 3 min to reload all 4 tubes. The short-hoist version weighs 7.6 tons, and there is no intermediate hoist stage between magazine and launcher.

The 2-tube launcher Type A (3.2 tons, 4 rockets on rocket table) fires M/50, Type E, and Type N rockets. Elevation limits are 0 to +90 deg, but the launcher can fire only between 0 and 60 deg. Launcher Type B employed a power hoist that loaded from a rotating loading table, itself replenished by push-button operated trucks, each moving 2 rockets at a time from storage tables in a magazine. The loading table held 8 rockets, but each storage table held another 6. This version trained and elevated at 30 deg/sec.

Against a submarine at 100-m [328-ft] depth, times of flight at min/max range for M/50, Type E, Type F, and Type N are, respectively, 14.2/19.4, 16.0/25.3, 19.3/28.5, and 24/36 sec. Nonrecoverable training rockets are Types L (Lilli, for M/50) and M (Mimmi, for ERIKA) (both 80 mm). The recoverable practice rockets are M/53, Type H, Type K, and Type P for, respectively, M/50, E, F, and N.

A French version, built by Creusot, has 6 barrels and usually carries 6 rails for illumination rockets. It is Model 1964, and it can be reloaded in less than 60 sec. The French had previously used the Swedish 4-barrel launcher. Maximum rated range is 1600 m, the French navy using rounds with 100 kg of explosive. Total system weight, including remote control, is 16,000 kg. The French version weighs 7700 kg (5700 kg for the mount proper), typically with another 10,100 kg of ammunition (36 rockets).

The Bofors 375-mm system was originally developed for the Royal Netherlands Navy, which placed it in service in 1954. Current Bofors 375 users (*indicates the 2-barrel version,** the 4-barrel version; others are 6-barrel) are Belgium (4 *Wielingen* class), Brazil (6 *Niteroi* class*), Egypt (2 *Descubierta* class*), France (17 *d'Estienne d'Orves* class), Germany (4 *Hamburg* class** and 5 *Thetis* class**), Indonesia (3 *Fatahillah* class*), Japan (6 *Yamagumo* class**, 3 *Minegumo* class**, 2 *Yubari* class**, 1 *Ishikari* class**, 4 *Isuzu* class**, and 2 *Akizuki* class**), Malaysia (2 FS-1500s*), Morocco (1 *Descubierta* class*),

Nigeria (2 *Erin'mis**), Peru (6 *Friesland* class**), Spain (6 *Descubierta* class*), and Turkey (3 ex-German *Koln* class**). Bofors 375s in Japanese service are designated Type 71. Although there is some question as to the continued value of the 375 against submarines at long range (see the notes on the projected NATO low-cost ASW weapon, above), this system is probably also valued as an antitorpedo measure. At least in the Belgian navy, it is the standard counter to a torpedo, liked for its quick reaction time in a line-of-bearing shot (presumably, the hope is that the explosion will derange the torpedo's homing system).

◆ Elma

This lightweight ASW mortar is designed to attack midget submarines in Swedish coastal waters. Development began in mid-1983, and first deliveries came a year later. Elma is to arm the Swedish fast patrol craft and *Landstort*-class minesweepers.

The system, produced by FFV and Saab, consists of four 9-barrel mortars firing 100 mm × 267 mm, 4.2-kg [3.9 × 10.5 in, 9.3-lb] shaped-charge contact-fuzed grenades. The grenades sink nose-first, and the shaped charge was developed from that in the Carl Gustav 84-mm antitank rocket. The barrels are mounted at a fixed 30-deg elevation, and range is about 250–300 m [267–330 yd].

In theory hits from these grenades will force a submarine to the surface without sinking it instantly, thus enforcing Swedish sovereignty in the least lethal possible way. The shaped charges should be able to penetrate the inner hull of a double-hulled submarine (at least 1 of moderate size), and thus a submarine commander choosing not to surface will have to risk the loss of the craft.

The LLS-920 launcher is nonmagnetic, and it was modified from an earlier design that had been proposed by Saab for launching of Philax chaff grenades. A hand lever adjusts the splay of the tubes, for the desired dispersion. Grenades are launched by charges fitted into the rear of the launch tubes. The firing of a 9-grenade salvo is spread over 2 sec to limit deck loads.

The ELMA ASW launcher on d

The ELMA grenades

Elma. (FFV)

In January 1985 the system was ordered modified to allow it to engage targets in water only 10 m [33 ft] deep. Later the bombs were further modified so that they armed upon hitting the water, so they could engage even shallower targets. In addition, Saab modified the system so that it could fire chaff/IR decoys.

Finland became the first foreign buyer of the Elma system, for its *Helsinki II*-class fast attack boats. Each will carry 4 LLS-920 launchers.

With the collapse of the Angler program (see above), the Swedish navy is considering (1990) 2 alternative developments of Elma. One would have increased range and would be mounted on the forward gun shield so that it could be trained. The alternative is to reduce Elma's diameter so that it can be fired from a 57-mm gun. This proposal recalls the World War II Shark projectile, which could be fired at an underwater target by a 4- or 5-in gun.

◆ Malin

This "incident weapon," announced in 1983, is a magnetic limpet mine that attaches itself to a submarine, emitting a traceable signal until removed. Malin makes tracking easy, and it is a nuisance that cannot be removed unless the submarine surfaces and sends someone out to find the mine on the hull. Malin is reminiscent of the U.S. "clicker" of the 1950s, a magnetized noisemaker that could be dropped on a submarine and that could generally be removed only if the submarine surfaced. Malin was devised to counter supposed Soviet midget submarines operating in Swedish waters.

◆ SAM 204

SA Marine's helicopter-dropped depth charge has a hydrostatic fuze (variable from 15–80 m [49–262 ft] in depth) and a variable charge (50–250 kg [110–550 lb] of high explosives). The fuze is unusual in being immune to transient pressure waves caused by other explosions, so depth charges can be dropped in salvo. Unlike the fuzes of other air-dropped depth charges, this fuze is set in the cockpit.

USSR

RBU is the Soviet designator (*Raketnaya Bombometnaya Ustanovka*, or Rocket Depth Charge). Former MBU designators reflect an earlier, erroneous Western belief that these weapons were mortars like the British Limbo.

◆ MBU-900

This weapon entered service about 1954 and may survive on board *Kronstadt*-class subchasers transferred abroad. The 25-kg solid-fuel rocket (warhead about 2 kg [55/4.4 lb]) has a range of about 900 m [980 yd]—hence the designation—and a speed of about Mach 0.5. The Soviets call this system a "jet-propelled depth-charge thrower." It is similar in configuration to the U.S. Mousetrap (Mk 20/22).

This weapon was also manufactured in China.

A Soviet equivalent of Hedgehog, MBU-600, survives on board 2 Bulgarian Rigas. The Soviets replaced this weapon in their own ships with RBU-2500s; the East Germans used RBU-1200s.

◆ RBU-1000

This launcher employs 30-cm rockets (as in RBU-600), but the barrels are longer, about 1.8 m [71 in]. Presumably, the warhead is the same but the rocket is longer, with more propellant, to achieve the greater range reflected in the new designation. The barrels are arranged in a horseshoe, and they load automatically, barrel by barrel, vertically; the barrels fire in sequence. RBU-1000 is in many modern Soviet large combatants (*Kara*, *Kresta-I/II*, *Kashin*, and *Sovremennyy*; also the large underway replenishment ship *Berezhina*). Range is 1000 m [1100 yd].

Except in the case of the *Berezhina*, RBU-1000 is mounted on a ship's quarter. In this position it is more likely an antitorpedo than an antisubmarine weapon, projecting a noisemaker decoy. The Soviets also have a towed noisemaker, but there

RBU-1000 rocket launcher on board the cruiser *Kerch*, 1989. This device is mounted on the ship's quarter, firing aft. *Kresta-II*- and *Sovremennyy*-class ships carry RBU-1000s in similar positions, which would be very reasonable if the weapon had a secondary antitorpedo (e.g., deployed noisemaker) role. The U.S. Navy experimented with a rocket-launched antitorpedo noisemaker, NAE, about 1948, ultimately discarding it because the launcher, Mk 31, presented too many hazards. Towed noisemakers were preferred. Other Soviet classes engaged in ASW lack any equivalent to RBU-1000 aft. Most carry a towed torpedo decoy. (Eric Grove)

is always the possibility that a torpedo attracted to the decoy will continue onward to the towing ship. Several navies, therefore, have investigated rocket-thrown noisemakers, which can be projected farther from a ship. The only current Western example is under development by the French navy.

RBU-1000 may also be a barrage antitorpedo weapon, relying on concussion to destroy or disable oncoming homing torpedoes. Again, similar devices have been projected in the past by the U.S. and Royal Navies. In each case, the project has died for 2 reasons: first, the rate of false alarms was so high that excessive weights of antitorpedo charges had to be carried; second, it was never clear just how much explosive was needed to be sure of killing the oncoming weapon. These problems still beset the U.S. SSTP program (see below).

Although the first 2 *Kirov*-class cruisers lack any RBU-1000, the third ship of the class, *Kalinin*, carries 2 examples of an RBU-1000 follow-on, with 6 tubes of greater size.

The earlier NATO designation was MBU-4500A.

◆ RBU-1200

RBU-1200 has 2 horizontal rows of 25-cm [9.8-in] barrels, 3 above 2. Barrel length is 1.4 m [55 in]. The launcher elevates

RBU-1200s on board an SO-1-class subchaser, 1968. (SOVFOTO)

for range but is fixed in train. The 70-kg [154-lb] rockets carry 34-kg [75-lb] warheads. Range is 1200 m [1300 yd]. This launcher is found on board T 58 patrol ships, *Natya*-class minesweepers, and *Pauk*-class ASW craft. The weapons in *Pauks* train for loading, but all these weapons fire dead ahead.

A PRC-manufactured equivalent uses 40-kg [88-lb] rockets with 3-kg [6.6-lb] warheads, to achieve a range of about 2000 m [2200 yd]. This version is carried on board *Jianghu*- and *Jiangdong*-class frigates, *Hainan*- and *Haiju*-class escorts, *Kronstadt*-class subchasers, and *Shanghai*-class motor gunboats. The last use suggests that there is an alternative shore-bombardment round.

◆ RBU-2500

RBU-2500 being loaded. (TASS)

This standard Soviet ASW projector of the early 1960s was introduced in 1957–58. RBU-2500 has 2 horizontal rows of eight 20-cm barrels (21-kg [46-lb] warheads) each, capable of train and elevation. Maximum range is 2500 m [2730 yd].

◆ RBU-6000

The carrier *Baku* introduced a new RBU launcher, seen here. The cylindrical vertical launchers immediately abaft the breakwater are for SA-N-9, and the big tubes are for SS-N-12. (U.S. Naval Institute)

RBU-6000 forward, on board the cruiser *Kerch*, 1989. This is the standard Soviet long-range ahead-thrown ballistic weapon, supplementing missiles such as SS-N-14. (Eric Grove)

This launcher consists of twelve 1.6-m [63-in] barrels arranged in a horseshoe, automatically loaded when they are elevated into the vertical position, barrel by barrel. The barrels fire in sequence, by pairs. RBU-6000 was introduced in 1960–61 and is very widely used in the Soviet fleet. Maximum range is 6000 m [6600 yd]. The old NATO designation was MBU-2500A.

◆ RBU-10000

This is a new launcher first observed on board the carrier *Baku* in 1989; it is presumably the replacement for RBU-6000. The new launcher has 10 larger-diameter tubes in the familiar horseshoe arrangement. The same launcher appears on board the new cruiser *Kalinin*.

RBU-10000 (ten thousand) is a NATO, rather than a Soviet, designation.

◆ SUW-N-1

Dimensions: 0.55 × 9.00 m [21.7 × 354 in]

Weight: approx 2300 kg [5070 lb]

Warhead: nuclear **Range:** 70,000 m [77,000 yd]

An unguided nuclear ASW missile, SUW-N-1 is a navalized version of the FROG-7 army weapon. Unlike the U.S. ASROC, SUW-N-1 apparently has no provision for control in range. It is carried only on board the helicopter carrier/cruisers of the *Moskva* and *Kiev* classes, which presumably rely on Hormone helicopters, using dipping sonars, for final target localization. FRAS might be considered the ultimate development of the RBU idea, substituting a single massive explosion for the multiple small explosions of the RBU rounds.

This weapon was formerly called FRAS-1 (Free Rocket Over Sea) in analogy with the land-based FROG (Free Rocket Over Ground).

The details above refer to FROG-7A, which entered service in 1965. References to SUW-N-1 generally give its range as about 16 nm, but the 70 km given for FROG-7A would be more logical if the weapon was adopted to exploit possible CZ performance by the big LF hull sonar of the *Moskva* class. For the land-based weapon, reaction time to fire is typically 15 to 30 min.

FROG-7 fires to a fixed range determined by the elevation of its launcher. It is analogous to the old U.S. Honest John nuclear-armed rocket. A later version, which probably is not the one modified as SUW-N-1, has air brakes that open at a preset range.

Recently, it has been suggested that SUW-N-1 has an alternative torpedo-carrying version.

◆ Depth Charges

Many ships still carry depth charges and throwers, and similar equipment was widely exported to Soviet client states. There are 2 standard depth-charge mortars: BMB-1, now largely gone, was a spade-and-arbor type with the arbor fitting inside the barrel. In BMB-2, the entire depth charge fits within the mortar

barrel. All Soviet depth charges are cylindrical. Standard internal and external rack capacity is 10 charges per rack.

The standard types are B-1, 4VB, M-1, and 4VM. Characteristics are as follows:

	Dimensions	Weight		
		Total	HE	Settings
B-1	44 × 72 cm [17 × 28 in]	166 kg 366 lb	135 kg 298 lb	20–210 m 66–689 ft
4VB	46 × 73 cm [18 × 29 in]	163 kg 359 lb	115 kg 254 lb	15–210 m 49–689 ft
M-1	26 × 43 cm [10 × 17 in]	35 kg 77 lb	25 kg 55 lb	10–50 m 33–164 ft
4VM	19 × 63 cm [7.5 × 25 in]	22 kg 49 lb	16 kg 35 lb	10–25 m 33–82 ft

All charges are designed to be launched either by a surface ship or by an airplane.

There is probably also a nuclear depth bomb, carried by helicopters and aircraft as an alternative to a homing torpedo. It is not known whether this bomb is the same weapon used as an FRAS-1 or SSN-15/16 warhead.

UNITED KINGDOM

◆ Air-Launched Depth Charge Mk 11

Dimensions: 11 in × 4 ft 7 in (body section is 3 ft 2 in long)

Weight: 320 lb **Warhead:** 176 lb

Mk 11 is 1 of very few surviving Western air-launched depth charges; the details describe Mod 3, a new modified version with a stronger outer case to withstand high-speed drops and helicopter vibrations. The U.S. Navy abandoned conventional depth charges on the grounds that they had only a very small chance of killing a fast submerged submarine in deep water. However, modern homing weapons are generally unable to deal with a surfaced or near-surfaced submarine. For example, in the Falklands, British helicopters attacked the surfaced Argentine submarine *Santa Fe* with Sea Skua radar-homing missiles, but the weapons passed through the submarine's sail without damaging her pressure hull. A pair of Mk 11s forced the submarine aground in a sinking state. The advantage of depth charges is that, because they are hydrostatically fuzed, they cannot home accidentally on an irrelevant portion of the submarine. On the other hand, unless the submarine is caught at the surface, the depth charges will almost inevitably miss.

Mk 11 Depth Charge. (Sperry)

◆ Nuclear Depth Bombs

The Royal Navy uses nuclear depth bombs, popularly referred to as Lulus, which is the U.S. code name for Mk 57 (see below); it is not clear whether some or all British depth bombs are of U.S. type. The U.S. weapon was designed as a dual-purpose land-attack bomb and depth bomb. The British weapon may have similar characteristics, making it suitable for dual-purpose ships: that is, the British light carriers may find themselves used either for ASW or for ground support (as in Norway).

The British official reply to those proposing abolition of this weapon is that it is the only certain counter to fast deep-diving submarines, that existing air-dropped torpedoes either lack sufficient performance or else cannot be relied upon, particularly in the presence of countermeasures.

♦ Limbo

Limbo is a triple-barreled hand-loaded mortar (Mk 10). Range is varied (between 400 and 1000 yd) by opening gas vents, and the barrels are aimed by a combination of roll and pitch (which is also used to stabilize the mounting). The appropriate spacing between rounds is achieved by a short time delay in firing. The weapon is designed so that its shells always enter the water at the same angle (for any ship's speed): their underwater trajectory is easily predictable, for effective fire control. The shells are time-fuzed, to explode at a preset depth. Each projectile weighs 390 lb, including 207 lb of Minol.

The usual installation was 2 Limbos, to form a pair of triangular patterns above and below the estimated position of the submarine. In many cases, however, 1 of the 2 Limbos had to be eliminated to save weight. The total weight, for 1 Limbo mounting and a magazine holding 17 salvos (51 bombs), is about 35 tons. Lethal range is about 5 yd; however, at ranges up to 50 yd, light fittings will be shattered and pipes cracked. Serious psychological effects can be expected at even greater ranges.

Limbo was the ultimate development of World War II British ahead-thrown ASW weapons, beginning with Hedgehog. The associated sonar is Type 170. In 1988 only 4 Royal Navy ships

A Limbo mortar, 1986. (R. Cheung)

A Limbo practice round, 1986. (R. Cheung)

retained Limbo. Surviving Limbo installations are Canada (the *St. Laurent*, *Mackenzie*, and modified *Restigouche* classes), Chile (the ex-*Achilles*), India (the *Leanders* and *Trishul*), Indonesia (the ex-Tribal class), Iran (the Mk 5 frigates), Malaysia (the *Rahmat* and *Hang Tuah*), Pakistan (the *Leander* class), and the United Kingdom (some *Leanders*).

♦ Squid

This triple ahead-thrown mortar (Mk 6) was introduced in 1943. Unlike Hedgehog, Squid fires depth charges that explode at a preset depth. Although Hedgehog entered service first, both Hedgehog and Squid were conceived simultaneously and were developed in parallel, and Squid outlasted Hedgehog in postwar British service. Squid was the first ASW weapon to be fully integrated with a sonar, its depth pistols being set automatically by a depth-determining sonar (usually Type 147 in World War II). Each 394-lb projectile (11.93 × 56.5 in) carries 207 lb of Minol II and sinks at about 44 ft/sec. The pattern for each projector is a triangle with 120-ft sides, and the standard installation is a double Squid producing a double layer with charges about 60 ft apart vertically, the hope being that the submarine is sandwiched between them. The mountings are designed to fire dead ahead, but they can tilt about 30 deg to compensate for roll and yaw, and also for minor course errors. The middle barrel's splash range is set at 270 yd (mortar 9 ft above water; for each additional 3 ft of height, the range increases a yard). The firing interval is 0.28 sec.

There is also a shallow setting (20 ft), introduced late in World War II, that can be used against a submarine detected either on the surface or just below (e.g., by radar detection of a periscope). In such a case, radar data are fed directly into the sonar's range and bearing indicators.

Squid is still in service on board 1 Bangladeshi frigate, 2 Chilean destroyers, and 1 Iranian "Battle"-class destroyer. In these ships the projectors are well above the water line, and range is 380 yd.

SQUID. (A. Raven)

UNITED STATES

♦ Hedgehog (Projector Mk 10/11)

This World War II standoff mortar was installed on board all U.S. World War II escorts and on board many U.S. destroyers during the 1950s, and Hedgehog survives on board some units in foreign navies. Existing units are fixed in train and elevation, although the mortar spigots can be rolled back and forth to stabilize them against the roll of the ship and to move the point of impact in train (by up to 25 deg).

Hedgehog fires 24 impact-fuzed fast-sinking rounds from spigots, the bombs forming an elliptical (Mk 10) or circular (Mk 11) pattern in the water. The standard post-World War II installation is 2 Mk 10s or Mk 11s that fire together. Typical pattern dimensions for the double Hedgehog: Mk 10, 195 ft wide and 168 ft in range at an average range of 283 yd; Mk 11, 267 ft in diameter at a range of 267 yd. Maximum bomb velocity is 175 ft/sec, and a typical flight time is 10 sec, plus 18.2 sec to sink

Fixed Mk 11 Hedgehog on board USS *Cassin Young* (museum ship), 1986. (A. Raven)

to 200 ft. Total installation weight, including the usual 6 reload salvos, is 28,720 lb.

Surviving fixed Hedgehog installations are in Brazil (5 FRAM II destroyers), Chile (2 FRAM IIs and 1 *Charles Lawrence* class), Greece (1 FRAM II DDR, 1 *Allen M. Sumner*, 4 *Fletchers*, and 4 *Cannon* class), Indonesia (4 *Claud Jones* class), Korea (2 FRAM II *Gearings*, 2 FRAM II *Sumners*, and 1 *Fletcher*), Myanmar (Burma) (1 PCER and 1 former minesweeper), the Philippines (2 *Cannon* class and 2 *Auk* class ex-minesweepers), Taiwan (1 *Wu-Chin II Gearing*, 2 *Wu-Chin I Sumner* FRAM IIs, 4 *Sumners*, 4 *Fletcher* class, 3 *Auk* class, and probably still some on board *Crosley*-class ex-transport), Thailand (1 *Cannon* and 2 *Tacoma* class), and Turkey (1 FRAM II *Sumner*, 1 *Smith* class destroyer minelayer, and 2 *Berk* class). The equivalent British Hedgehog is extinct.

◆ Hedgehog (Projector Mk 15)

The trainable Hedgehog spigot mortar is found on board post-war-built U.S.-designed 173-ft patrol craft in the Turkish and Chilean navies. In these cases the weapon is controlled on the basis of SQS-17A sonar data. The mortar is stabilized and power-trained; total weight is 17,425 lb (26,785 lb including the standard allowance of 6 patterns). The typical pattern was a 279-ft circle at a range of 265 yd, the bombs taking a total of 29 sec to reach a depth of 200 ft (10.4 sec in flight, 18.6 in the water). Mk 15 also survives on board the old Japanese destroyers

Hedgehog Mk 15. (Author)

(now auxiliaries) of the *Akizuki* and *Ayanami* classes and on board the Turkish destroyer *Kocatepe*.

◆ Mousetrap (Projector Mk 20/22)

Mousetrap is a World War II-designed rocket standoff weapon for small craft, installed on board many patrol craft supplied to U.S. allies through the early 1970s. Rocket propulsion was adopted to avoid the weight penalty (in deck strengthening) associated with Hedgehog. Mk 20 consists of 2 sets of 4 rails, which can be folded down to lie flat on deck; Mk 22 has 2 sets of 8 (4 rails on top of the original 4). The warhead was that of Hedgehog, but with a rocket motor (i.e., with a slower-burning propellant). The 16 projectiles of a Mk 22 formed a pattern about 80 yd wide at a range of 300 yd.

Surviving Mousetrap installations are in Iran (1 *Cape*-class cutter), Spain (3 U.S. 83-ft types), and Turkey (the *Girne*, 12 AB 25 class, 4 PGM 71 class, and 4 U.S. 83-ft types). Mousetrap may also be mounted on board U.S.-supplied or license-built PGM 39/71 series gunboats: Brazil (6), Dominican Republic (1), the Philippines (5), and Vietnam (10). It was originally on board the U.S. Coast Guard 95-ft patrol boats, on which the gunboats were patterned.

Mousetrap. (National Archives)

◆ Depth Charges

The U.S. Navy currently uses only nuclear depth bombs. The standard nuclear depth bomb is based on the B57 weapon and is designated bomb Mk 101 or "Lulu" (18 × 92.4 in, 1200 lb). B57 can be used either as a depth bomb or (in a streamlined casing) as a lay-down bomb against land targets. B57 can be delivered both by LAMPS helicopters and by fixed-wing aircraft.

One squadron each of Dutch P-3Cs (13 aircraft) and Italian Atlantics (9 aircraft) are reportedly certified to deliver U.S.-supplied B57 depth bombs. In each case, they succeed earlier aircraft that had this capability (Neptunes in the case of the Netherlands, Trackers in the case of Italy). British Nimrods are certified to deliver U.S. B57s, which presumably are backups to the British-built WE-177Cs.

U.S.-type streamlined (teardrop) depth charge, on board USS *Cassin Young* (museum ship), 1986. (A. Raven)

In June 1987 the *Bulletin of the Atomic Scientists* estimated that the U.S. stockpile contained 900 B57 depth bombs. This weapon is scheduled for retirement in the near future in favor of a new nuclear depth bomb. See the discussion of nuclear bombs in the Strike/Surface Warfare section.

Many conventional depth charges formerly used by the U.S. Navy probably survive in Allied navies and, therefore, deserve description here.

The standard air-dropped weapon was the Mk 54 depth bomb (13.8 × 52.5 in, total weight 354 lb, charge 250 lb of Torpex or HBX). Mk 54 became the standard NATO air-launched depth bomb; it is currently used by the French navy and probably by other NATO navies. A new depth bomb is being developed, in the form of a hydrostatic fuze (SAM-104) for Mk 82 bombs, to give SH-3s and other helicopters the ability to attack surfaced and near-surfaced submarines. The SAM-104 program was inspired by the successful depth-bomb attack on the *Santa Fe* in the Falklands (see the U.K.'s Mk 11, above).

The standard shipboard depth charge was the fast-sinking (teardrop-shaped) Mk 9, provided with fins that spun it to stabilize it while it sank. Mk 9 carried 200 lb of explosive and sank at 22.7 ft/sec (settings 30 to 300 or 600 ft). Overall dimensions were 17.7 × 27.6 in; total weight, 340 lb. The initial version, Mod 0, sank at 14.5 ft/sec. Mk 14 is an influence-fired version of Mk 9, using an acoustic pistol.

Some earlier cylindrical depth charges (Mk 6) may survive. Dimensions are 17.7 × 27.6 in; total weight is 420 lb, including 300 lb of explosive. Burst depth can be set at 30–1000 ft. Sinking rate is about 8.5 ft/sec.

COUNTERMEASURES

Underwater training targets are, in effect, submarine simulators and are, therefore, viable decoys, although they are not generally so described. Some of them are listed in the U.S. systems below.

FRANCE

In 1984 the French navy funded studies by Lacroix and Thomson-CSF of thrown torpedo countermeasures, with preliminary trials between December 1984 and January 1985. The grenades would be fired from SAGAIE countermeasures launchers (see the AAW section for launcher details). Three alternatives were considered: a pyro-acoustic noisemaker, a gas generator that would produce a bubble curtain to hide a ship (just like an underwater chaff cloud), and an expendable jammer. The bubble cloud would tend both to hide the noise of the ship and also to reduce the ability of an active homing torpedo to detect a ship. The expendable jammer might be used to monitor the approach of the torpedo and communicate with the ship, which in turn would order the jammer to produce noise or deception signals.

As described in 1986, the jammer would be deployable about 20 sec after alerting, 3800 m [4160 yd] from a ship, to operate for 4–8 min. As of 1988, Lacroix was designing a 130 × 780 mm [5.1 × 30.7 in] round (50 kg [110 lb]), operating in less than

3 sec, at ranges of 10–200 m [11–220 yd], carrying a 25-liter payload of bubble generators, pyro-acoustic noise sources, or an active decoy that would respond to the torpedo's sonar and emit doppler-shift-compensated false echoes. Safare-Crouzet and Thomson Sintra are developing an electro-acoustic decoy.

Reportedly, a self-propelled antitorpedo direct-kill (kinetic-energy) weapon is under consideration.

♦ SLAT

SLAT (*Système de Lutte Anti-Torpille*) is an antitorpedo system for ships not equipped with the SLASM ASW system (see above), such as carriers, AAW destroyers, and the new general-purpose frigates. Directional (presumably at least dual-line) towed arrays will provide torpedo warning, and the countermeasure will presumably be 1 of the types described above, launched by SAGAIE (see the countermeasures in the AAW section).

♦ Spartacus

Thomson Sintra, CSEE, and Lacroix jointly exhibited this surface-ship antitorpedo countermeasure at Bourget Naval in 1990. A painting of the system shows a frigate towing what appears to be an ATAS sonar and firing a rocket decoy (which floats suspended from a sonobuoy-type float) into the path of an oncoming torpedo detected by the towed sonar. Typically, the system would fire 3 decoys in sequence to seduce the torpedo far enough away from the ship so that it could not circle back to re-attack. Decoys will be launched automatically, subject only to veto by the ship's commander. They may be fired from either DAGAIE Mk 2 or SAGAIE launchers and can be deployed at ranges up to 3000 m. Both pyro-acoustic and electro-acoustic payloads are being developed: an anti-wake follower is a likely future development.

ISRAEL

♦ ATC-1

Rafael's Acoustic Torpedo Countermeasure (decoy) for the Israeli navy was announced in 1986; ATC-1 is also usable by merchant ships. Dimensions of the towed body are 30 × 120 cm [12 × 47 in], and it weighs 25 kg [55 lb]; launch and recovery gear weigh 800 kg [1760 lb], and the electronics cabinet onboard ship weighs another 190 kg [419 lb], with a 10-kg [22-lb] remote control unit.

ITALY

♦ C303

This Whitehead submarine antitorpedo countermeasure system uses an EFFECTOR expendable device, which can be configured either as a decoy or as a sonar jammer.

USSR

A noisemaker (acoustic decoy) on board a Soviet Krivak-class frigate, 1990. Most Soviet decoys are not buoyant, and they are streamed with separate floats. (H. J. Verhoeven)

UNITED KINGDOM

◆ Bandfish (Amulet)

Dowty's expendable submarine self-protection countermeasure is designed to float in the water while transmitting active pulses to confuse an oncoming active-homing torpedo. Bandfish is programmable before launch. Bandfish, which won a competition against a Marconi countermeasure, is named Amulet in British naval service. Dimensions are 102 × 995 mm [4 × 39.2 in], and weight is 12 kg [26 lb]. Shelf life is 5 yr.

A Bandfish decoy is loaded into a submarine signal ejector. (Dowty)

◆ Foxer/Unifoxer

These towed torpedo decoys were developed during and immediately after World War II. They emit broad-spectrum noise and reportedly were retained in storage because they could simulate the noise of, for example, a convoy. They were used as countermeasures by merchant ships and some auxiliaries during the Falklands War.

Derived from a wartime acoustic mine sweep, Foxer consisted of 2 steel pipes held loosely in a frame. When towed, they hit each other to produce the noise. Escorts towed a string of 2 Foxers 100 yd apart (this distance was maintained by mine-sweeping kites), on the theory that the German acoustic torpedo had only a limited FOV and might miss a single decoy. The devices were towed 200 yd astern. Foxer weighed about 3 tons

and could not be towed at speeds over 14 kt. It tended to break up under tow (average lifetime was 25 hr) and to interfere with sonar (asdic). Foxer's production began in July 1943.

It turned out that the German torpedo had a very wide FOV, so a single noisemaker, Unifoxer, could suffice. Unifoxer was issued beginning in February 1944. It was towed 350 yd astern at 10 kt (maximum tow speed was 20 kt), and it covered the 5–50-kHz band.

◆ TALISMAN

This British project for an antitorpedo project later became joint U.K.-U.S. project.

◆ Type 182/Graseby G738

This tunable narrow-band noisemaker uses a magnetostriction transducer. Wartime experience showed that the broad-band units, such as Unifoxer, jammed escort sonars. It was soon discovered that acoustic homing torpedoes themselves operated on fairly narrow bands; given sufficient intelligence, a noisemaker could be tuned to the appropriate frequency so that it could operate without jamming a sonar operating on a different one. Work began late in 1944, leading to Type 155 (Cheater), a decoy embodying a frequency-modulated (FM) noise source, to be towed 350 yd astern. Although Cheater was not ready in time for wartime use, it appears that the current standard British decoy, Type 182, was an extension of the same basic idea.

The Type 182 fish is 21 in in diameter and 79 in long and weighs 163 lb. Typically, 2 towing drums are arranged side by side at the stern, the decoy itself being handled by davit. The

A Type 182 decoy and its handling crane on board the frigate *Andromeda*, 1985. (R. Cheung)

Type 182 decoys. (R. Cheung)

decoy is designed to be streamed 400 m astern. In its present form the decoy can either simulate the noise characteristics of a ship or produce sonar-like pulses (CW) that can jam or confuse an active-homing torpedo. Both modes can be transmitted simultaneously. Shipboard signal generators are duplicated so that the system can continue to operate even in the event of 1 fails.

Type 182 was designed to protect destroyers and frigates at speeds of up to 25 kt and larger ships at speeds of up to 18 kt. To decoy passive torpedoes, it emits modulated white noise (at an intensity of 20 dB above the ship's radiated level) at 20–80 kHz. To jam (not decoy) active homers, it produces a high-intensity tone signal swept 4 times/sec over the 20–80-kHz interval, modulated (1 msec on, 1 msec off).

Graseby G738 is the export version of Type 182, and GI738 is a solid-state version. As of 1983, GI738 had been exported to both Argentina (for MEKO frigates) and India.

G738 produces 2 independent outputs: AM noise to simulate a propeller and swept CW to jam torpedo sonar.

◆ ATAAC

The DBE Technology (Ferranti subsidiary) antitorpedo acoustic countermeasure is a noisemaker designed to be fired from a standard British or U.S. chaff launcher. ATAAC was announced in 1987. Rounds are programmed immediately before launch, to produce broad-band high-power noise. ATAAC can also be produced in 3- or 4-in-diameter form, for ejection from standard submarine countermeasures tubes; and reportedly a 21-in self-propelled wire-guided version, for firing from submarine torpedo tubes, was developed in 1987–88.

DBE began work with Whitehead in 1987, and the resulting submarine-launched decoy is now (1990) in preproduction service. DBE (Ferranti) makes the sonar portion.

The Royal Navy currently uses the U.S. ADC Mk 2, and the Whitehead device was offered as an alternative. Ferranti claims that it develops more power and has longer endurance. However, ADC Mk 2 hovers better, using its small propeller to keep it between preset depth limits (ATAACS sinks on a retarding drogue). The Royal Navy also uses Bandfish; it has both 3- and 4-in signal ejectors.

Ferranti has designed additional seduction countermeasures for Whitehead (noise and real-time echo repeaters) and has built prototypes. It manufactures the analog elements of the devices but not the signal processor (which Whitehead makes under license from Gould).

ATAACS itself was designed to be compatible with the Shield

chaff rocket-launching system. It can also be manufactured in other calibers. Thus far (mid-1990) it has found no buyers. It is reminiscent of the U.S. practice, immediately after World War II, of firing noisemakers (NAE beacons) by rocket from ASW ships. This system was soon discarded because the rocket launchers had to be able to train and then to fire without warning, endangering personnel topside. Presumably, a modern fixed-train launcher could fire at such range that the ship could maneuver it into position, and the associated maneuver-advice device would cause the ship to turn appropriately.

At Comdef '90 (in November 1990) Strachan & Henshaw showed a sketch of an abortive triple torpedo-countermeasure launcher, designed for a client about 18 months earlier. It resembled a subcaliber Mk 32 tube (capable of elevating) mounted on a pedestal and was, presumably, intended to fire ATAACS or some similar decoy.

In 1987 it was reported that Graseby was developing a similar software-controlled decoy, actuated directly by a ship's sonar.

◆ Mintec Sonar Intercept System

This digital, active-sonar intercept system, incorporating transputer processors, was announced in 1990. Mintec, the manufacturer, claims that it is much simpler than earlier systems, only a single pair of wires connecting the array electronics and the main processor. The arrays themselves are smaller than existing types. Presumably, the use of a single pair of wires implies that sampled hydrophone data are transmitted sequentially, as in the SBF 256 beam-former described above.

◆ Sea Siren

This new Graseby torpedo decoy was first shown at RNEE 1989. It is microprocessor-based and user-programmable.

◆ SSDE

Submerged signal and decoy ejector, currently standard on board British submarines, is supplied by Strachan & Henshaw (which also makes the current torpedo handling-and-discharge systems). SSDE uses an air-actuated water ram adjacent to the vertical decoy launcher tube in the submarine's pressure hull. The company offers automatic store loading (from a magazine below the launcher) and a direct connection with the submarine combat system as options; it also offers a simple manually loaded version. SSDE can accommodate both standard British (4-in diameter) and U.S. (3-in diameter) decoys, up to 39 in long. Although announced in 1990, it has apparently been in service for some years.

◆ DMT

Thorn-EMI's Deep Mobile Target can be fired from submarine and surface-ship torpedo tubes. Dimensions are 12.75 × 129 in; weight is 520 lb. Speeds are 0 kt, 8 kt (for 100 min), 14 kt, and 22 kt (for 8 min). Depths are 30–1200 ft. DMT dives or climbs at 30 deg (0.84 ft/sec/kt) and has a turning radius of 250 ft (rate of turn is 0.38 deg/sec/kt). Transponders are provided for active/passive homing at 30–70 kHz and active/passive sonar at 7–11.5 kHz, and there is a miss-distance indicator at 125 kHz. DMT can be commanded to stop. It entered service in 1983 and was used in the Spearfish, Tigerfish, and Stingray programs. The cheaper towed Type 2058, which entered production in 1985, is its successor.

EMI Electronics's Deep Mobile Target can be fired from submarine and surface-ship torpedo tubes. Dimensions: 12.75 × 129 in, weight 520 lb, speed 8–22 kt, maximum depth 1200 ft.

UNITED STATES

◆ ADC Mk 1

Acoustic Device, Countermeasure is a submarine-launched sonar countermeasure powered by a seawater battery. Dimensions: 5-in diameter, 72.75-in length, weight 41.3 lb. It was probably introduced about 1973.

ATAAC decoy in surface-launched form, as displayed at Farnborough. [Author]

ADC Mk 2 Mod 0. The acoustic projector is at the top. It contains the ceramic transducers and impedance-matching networks. Adjacent to it is an electronics section (the object exposed at top left) containing the signal generation and amplification circuits. Power is provided by the seawater battery (center left). At bottom left are the motor and propeller of the hovering module, which also provides the decoy's buoyancy as it hovers in the water. The hover motor is pressure-controlled to maintain nearly constant depth. Dimensions are the standard 3×39.5 in of a submarine's signal tube (weight 7.5 lb). (Hazeltime)

◆ ADC Mk 2

Emerson's electro-acoustic torpedo countermeasure was originally designated ETC-1. It is a submarine-launched torpedo decoy, hovering (by means of a small propeller) and emitting signals at a preset depth. Dimensions: 3.0×39.5 in (weight 7.6 lb). ADC Mk 2 was introduced in 1978; by 1987, when it was first shown publicly, over 2800 had been manufactured.

◆ ADC Mk 3

This torpedo countermeasure is designed for launching from CSA Mk 2. Total weight is 125 lb. Operational evaluation was completed in FY88. As of early 1989, it was expected that a production contract would be awarded in FY89. The Operational Requirements for ADCs Mk 3 and 4 (and for CSA Mk 2) were issued in December 1976.

◆ ADC Mk 4

This submarine-launched sonar jammer, complementing Mk 3, is launched by CSA Mk 2. Dimensions: 6.25×106 in (weight 100 lb). Bids for full-scale engineering development were solicited during FY88, and the FY89 program included preliminary and critical design reviews of engineering-development models (EDMs) for Mk 4.

◆ ADC Mk 5

Sonar countermeasure. Dimensions: 6×106 in (weight 110 lb).

◆ ADC Mk 6

This expendable torpedo countermeasure is intended as part of the Basic Acoustic Warfare System (AWS), for rocket launching from SRBOC surface-ship mortars. It contains 2 electronic signal generators. Diameter is 5.133 in, and weight is 30.44 lb. This nomenclature was assigned in 1977.

◆ ADC Mk 7

This mechanical sonar jammer is a motor-driven sound generator designed as a companion to Mk 6. Diameter is 5.133 in, and weight is 32.84 lb.

◆ ADC Mk 8

This mechanical torpedo countermeasure is a motor-driven sound generator similar in concept to Mk 7. Diameter is 5.133 in, and weight is 30.4 lb.

◆ ADC EX-9

The submarine mobile acoustic countermeasure, to replace the Mobile Submarine Simulator Mk 70, is a countermeasure for strategic submarines. Dimensions: 6×96 in (weight 100 lb). It is launched by CSA Mk 2.

◆ ADC EX-10

This surface-ship advanced acoustic countermeasure (AACM) was conceived as part of an early surface-ship torpedo-defense program (SSTD), about 1983. See the SSTD entry.

◆ BLR-14

Sperry's basic submarine acoustic warfare system (BSAWS) uses existing equipment to detect, evade, and counter torpedoes. It automatically alerts a submarine, rapidly classifies incoming torpedoes, tracks them, and semiautomatically releases decoys. This system uses the preformed beams of the existing submarine sonars for torpedo tracking. The detector is WLR-9A/12, and the classifier is WLR-14 (1975).

◆ BLQ Series

This decoy generation preceded the current one. These decoys may survive in foreign navies, and their characteristics, though obsolete, give some idea of what decoys are expected to achieve. At least the following were developed:

BLQ-1 Fixed jammer intended simultaneously to jam 3 ship or torpedo soars. Controlled from within the submarine, it listened for 5 sec and transmitted for 25. The first was delivered in December 1960, but it failed its operational evaluation.

BLQ-2 Mobile decoy and jammer against surface-ship sonars (submarine simulator). It carried a sonar repeater/jammer and also a beacon simulating the beat of a submarine propeller; it was launched from a submarine torpedo tube and followed a preprogrammed course (30–60 sec at 12 kt, then 19 min at 6–9 kt, at a depth of 50–300 ft). The first 5 were tested successfully in 1956, but BLQ-2 was never made in large numbers.

BLQ-3–6 A series of small-diameter (3×39 in) hovering decoys, first tested in breadboard form in 1962. They were ejected from the submarine's signal gun. BLQ-3 and -4 were jammers; BLQ-5 and -6 were sonar repeaters. These devices differed from their predecessors, the NAE series, in that they responded to sonar signals. The earlier devices were preset to emit over a given frequency range. Coverage of the full range of frequencies, in this case 7–70 kHz, required 2 separate devices.

BLQ-9 Successor to BLQ-2, and predecessor of MOSS (see below). It is a 10-in contact-breaking device with a speed of 8–10 kt, operating at 50–400 ft. BLQ-9 was initially a sonar repeater (blip enhancer) but later carried a sonar noise jammer. It also emits submarine sounds at 0.1–1 kHz. This decoy also simulated a submarine wake (which itself can be a sonar target) by passing seawater over lithium hydride. BLQ-9 and MOSS are characterized as contact-breakers. Six BLQ-9s were stowed in a modified torpedo-stowage cradle and ejected via the torpedo tube using temporary liners.

◆ CLAMS

Countermeasure launcher acoustic module set is a predecessor to the CSAs described below. It is made by Librascope, and it is carried by both strategic and attack submarines.

◆ CSA Mk 1

Countermeasures set, acoustic, is a quick-reaction countermeasures-launching system for strategic submarines. It employs launching device Mk 139. Decoys are launched by a gas generator. Dimensions are 6.5×87.54 in. This nomenclature was introduced in 1973, although the device may be older. The 5-in launcher is mounted externally.

◆ CSA Mk 2

Librascope's submarine countermeasures-launching system, for ADCs Mk 3 (torpedo) and Mk 4 (sonar), employs launcher Mk 151. Individual countermeasures devices (ADCs) are remotely selected and launched. It was conceived for ballistic-missile submarines (Mod 0), but Mod 1 will be installed on board *Sturgeon*-class attack submarines. Operational evaluation was com-

pleted during FY88. The FY89 program included the award of the CSA Mk 2 production contract and the completion of a launcher-system design for *Los Angeles*-class submarines. This has been a very protracted program; the original Operational Requirement dates from December 1976.

◆ CSA Mk 3

Countermeasures-launching system for the new *Seawolf*-class submarine. An unclassified 1987 data sheet shows capacity for up to 16 decoys, up to 6×106 in in size.

◆ Fanfare (T.Mk 6)

The standard U.S. towed torpedo decoy of the 1950s and 1960s is fitted on board FRAM destroyers. The characteristic installation includes a small spray shield protecting the towing winch. Two decoys are provided per installation. In U.S. service, Fanfare was replaced by Nixie, but many Fanfares probably remain in service in other navies.

Fanfare replaced the U.S. wartime FXR.

Fanfare on board the destroyer *Cassin Young*, showing the dual winches, each with its fish, and the spare fish between. (A. Raven)

◆ NAE/NAD/FTC

These World War II sonar-countermeasures designations have survived in generic form. Some of the countermeasures themselves may also have survived, at least in the smaller navies. Most of the countermeasures were intended for release from the standard U.S. 3-in signal tube, which limited them to dimensions of 3×39.5 in. The current CSAs are their lineal successors.

NAE is now the generic term for a noisemaker. The current version is NAE Mk 3.

FTC, the false-target canister, creates a false target by making bubbles, e.g., by letting seawater pour over lithium hydride. Unlike a mobile decoy, an FTC is released from a submarine to fill a volume of water with bubbles; it is the submarine equivalent of a chaff round.

◆ Nixie (SLQ-25)/SLQ-36

This towed noisemaker, made by Aerojet, was first produced in 1974. A total of 180 have been procured for the U.S. Navy, and many have been exported. The usual installation is a pair of winches with 2 Nixies, the decoys trailing through ports in the transom. They do not generally operate together; rather, 1 is available if a torpedo destroys the other. Nixie is about half the size and weight of Type 182. Towed body (TB-14) dimensions: 6 in (diameter) $\times$ 37.05 in (tail fin, 7.31-in diameter); weight is 46 lb. Nixie evaluation was completed in December 1970, and SLQ-25 was approved for service use in February 1971.

SLQ-25 is now being modified. The FY88-91 programs include 421 engineering change kits. The FY90 program includes

production of a Nixie towed-body engineering change and also of a Nixie power-amplifier engineering change.

SLQ-36 is the combined countermeasures tow (CCT), part of the new torpedo-countermeasures system. It comprises an improved Nixie, a magnetic countermeasure, a wake-homing-torpedo countermeasure, and a towed torpedo detector. The magnetic countermeasure is presumably intended to detonate torpedoes using magnetic exploders. This designation was assigned in 1983.

◆ SLQ-33

SLQ-33 is a towed acoustic simulator for escort battle groups. SLQ-33 is used for cover and deception and is van-mounted. Specifications for a product-improved version were completed in FY87. SLQ-33 is made by Honeywell. Towed body dimensions: 27.36 in (diameter) $\times$ 117 in (1950 lb).

◆ SLR-24

This passive acoustic-threat sensor (PATS) is a torpedo detector, part of the new (ca. 1985) U.S. surface-ship torpedo-defense program. The basic Operational Requirement (OR) was issued in March 1985, following a Navy Development Coordinating Paper of January 1985. SLR-24 would trigger either defensive maneuvers or an antitorpedo weapon, perhaps a converted torpedo. The SLR-24 advanced procurement program begins in FY90.

SLR-24 consists of a beam-former/signal conditioner, 1 receiver/signal processor, and 4 acoustic arrays: DT-511B/WLR-9, DT-593/WLR-12, a hull-mounted directional array, and a Martin Marietta towed torpedo detector. By 1990 it appeared that the big hull arrays had been abandoned. The inboard electronic elements are made by Norden.

◆ SSTD

Surface Ship Torpedo Defense is the current U.S.-British program. The 2 competing consortia are General Electric, Honeywell, Marconi, Plessey, and AT&T, Librascope, Dowty, Ferranti. The U.S.-British MoU on SSTD was signed 26 Oct 88. There is also a national (U.S.) SSTD program, and the connection between it and the 2 Nunn programs is not altogether clear.

An official description of the U.S. national program mentions modifications to torpedoes and acquisition of Mk 32 torpedo launchers (see also the list of versions of Mk 32, above, including 1, Mod 16, specifically for SSTD). Logos displayed at the U.S. Navy League show in 1989 showed a surface ship launching an undefined single object at an incoming threat torpedo, presumably a modified lightweight torpedo. Work is still proceeding on alternative concepts (see below).

The use of a homing kill weapon should solve a major problem of past attempts at antitorpedo defense, the excessive amount (particularly weight) of ordnance required to deal with each incoming torpedo.

The other central problem is the high false-alarm rate. It is presumably being approached via better detectors (such as the SLR-24 towed array) and better signal processing. The problem remains difficult, particularly in the face of intense sea noise in rough weather. On the other hand, beyond some particular sea-state, the sea noise will make passive homing against surface ships virtually impossible, and the roughness of the sea will probably make wake-seeking torpedoes ineffective.

This is a phased program. Phase I installations, presumably for torpedo detection (no extra torpedo tubes were fitted, so Phase I cannot have been the antitorpedo weapon), began in FY88. Presumably, too, the program initially applied only to the highest-value units (carriers), since the 1988 program description notes that, beginning in FY90, it was to be extended to surface combatants, the combat logistics force (underway replenishment ships), and to amphibious ships. That representation suggests that SSTD will employ a homing antitorpedo weapon. Such a development, which is presumably possible with modern forms of torpedo homing, would solve a major problem of earlier antitorpedo weapons, the excessive amount of ordnance needed to deal with each incoming torpedo. The

other central problem, a drastic reduction in the false-alarm rate, might be solved by better on-board signal processing. The problem remains difficult, particularly in the face of intense sea noise in rough weather. On the other hand, beyond some particular sea-state, the sea noise will make passive homing against surface ships virtually impossible, and the roughness of the sea will probably make wake-seeking torpedoes ineffective.

SSTD follows several false starts. Renewed interest in hard-kill torpedo countermeasures was inspired by the appearance of the big Soviet wake-following torpedo (Type 65), which would not respond to conventional noisemakers, no matter how sophisticated. By 1987, 2 separate programs, Antiship Torpedo Defense and Surface Ship Torpedo Defense, had both died. Under the Nunn Amendment, effort shifted to a joint U.S.-U.K. program, SSTO.

An R&D contract award is expected in 1991.

Several radical SSTO schemes, sponsored by DARPA, have been described by the press. They are outgrowths of strategic-defense research and are presumably being pursued under the BTI (balanced technology initiative) program. One approach is to use an electric (rail) gun or chemical reaction to accelerate an underwater projectile to supersonic speed; the other is to generate shock waves in the ocean to throw off or destroy a torpedo. DARPA let its first contract to the University of Texas Center of Electromechanics in 1985, to study the use of an electromagnetic launcher. Tests of projectiles made by a California company, PDA, at NSWC are said to have shown that water resistance is much reduced at very high speed because of the gas bubbles that surround the projectile on launch. EML of Hudson, Massachusetts, has reportedly developed a magnetic wave launcher, which has fired 3-in miniature torpedoes at the David Taylor Model Basin. In 1 series of tests the electromagnetic launcher fired the torpedo; in another it powered a launching piston.

At least 1 press report associated these exotic techniques with a blue-green (presumably underwater) radar. Like the more conventional antitorpedo measures, the exotic ones suffer the problem of false alarms. A blue-green radar, were it practicable, would solve that problem, but its range would be extremely limited. Presumably, a very fast projectile could make up for very short detection range. It might also be able to deal with salvo attacks, a problem that might well saturate a more conventional system based on some sort of homing torpedo.

◆ WLR-9A/9B/12/17

These acoustic intercept receivers (AIRs) for submarines are manufactured by Norden. The system typically consists of a sail-mounted sonar hydrophone, a receiver-processor, and a display group. WLR-9A provides some localization, intercepting low- and high-band signals of active sonars. The receiver-processor obtains frequency, bearing, and signal strength. WLR-9A is also used to detect enemy homing torpedoes using active seekers. Work on these systems began in the late 1960s. The current versions are automatic, presenting both CRT (raster scan) and digital readouts and identifying threats by comparison with libraries of ship, submarine, and torpedo sonars. These versions may also detect important transients such as those associated with torpedo and other weapon firings. Part of SAWS, the Submarine Acoustic Warfare System, also includes submarine-launched countermeasures.

WLR-5 was an earlier acoustic intercept receiver.

WLR-9A, which replaces WLR-9, uses DT-511B, DT-592A, and DT-593/WLR-12 HF hydrophones, all carried in 2 sonar domes. It automatically detects sonar transmissions and pulses and measures and provides digital display of sonar parameters, e.g., bearings, frequency, pulse width, pulse repetition period, and sound pressure level. It is more sensitive than WLR-9. WLR-9B has a new receiver-processor and can have a second DT-592A in place of the DT-511B. DT-592 operates at HF; it has a frequency range of more than 1 decade and provides data in 4 quadrants (1 preamp per quadrant), summing its outputs to determine signal bearing. WLR-9B encodes sonar parameters and

sends them to the submarine's BQQ-5B for further processing and display. B(V)1 has only 1 hydrophone (DT-593). B(V)2 has DT-511B and DT-592A. B(V)3 has a new receiver-processor and a DT-593 hydrophone. B(V)4 accepts serial digital data, e.g., own-ship's depth, heading, blanking, target, status, and wrap test data; it uses DT-511B and DT-592A. WLR-12 uses DT-544 and DT-593 (HF) hydrophones. DT-544 is similar to DT-512 but has an extended frequency range. It supplies data in 4 quadrants. Sonar signal parameters are displayed on a CRT and digital readouts.

These devices replace the French-supplied Velox (DUUG-1B). In the early 1960s the U.S. goal was to cover 1.1–70 kHz with frequency accurate to within 10% and bearing to within 5 deg. WLR-2 failed, and Velox (5–40 kHz, 20-deg bearing accuracy) was bought instead. A later intercept receiver, WLR-5, also failed.

◆ Mk 28

This target for warshot torpedoes is a converted torpedo body. Mod 2 was a half-length version, introduced about 1985, and presumably based on a Mk 37 torpedo body.

◆ Mk 30

Mk 30 is a torpedo-sized acoustic target used primarily to test deep-diving torpedoes, but it is also usable, in theory, as a particularly realistic decoy. Mk 30 is capable of about 30 kt. Mk 30 is the current standard U.S. submarine simulator, to be used as a target. Its characteristics suggest what sort of performance a torpedo-sized decoy can provide, although there has never been any indication that Mk 30 itself is considered a viable decoy (it would displace a torpedo, and submarines have too little torpedo stowage to afford such a decoy).

The target is 21 in in diameter and 20 ft (245 in) long, weighing 2700 lb. It can be fired from a 21-in torpedo tube or a rack, or dropped by a helicopter. Mk 30 tows a 300-ft array consisting of a hydrophone, a projector (to simulate submarine sounds), and a magnetic source (to trigger MAD gear). Speed is 7 kt (endurance 4 hr) to 30 kt (30 min); routine operating depth is 25–2000 ft (maximum depth 2500 ft). Turn rate is 0.25–8 deg/sec, depending on speed, and the target can climb at 2–20 deg. An acoustic command link controls depth, course, speed, and shutdown to a maximum range of 5000 yd.

This program began in the late 1960s but was much delayed by deep budget cuts. Westinghouse was the initial contractor, and the company delivered 2 Mod 0 to the Barking Sands Tactical Underwater Range (BARSTUR) early in 1970, for Pacific Fleet operational training. These units were 21 × 224 in (2520 lb), and speed, course, depth, and climb-dive and turn rates were controlled by an internal punched tape, rather than by an external acoustic link. In all, 11 Mod 0s were bought.

Northrop received the Mod 1 contract (11 targets) in 1972, with 7 more in FY73 and 4 in FY74. Development tests of Mk 30 Mod 1 began in FY72, the first unit being received in June 1973. Proof tests were conducted February–August 1974. Unit cost was \$895,833 in FY76, but it rose to \$2,557,143 in FY77, partly because of a Reliability Improvement Program. Between 1973 and 1976 reliability rose from 30% to 65%, against a goal of 80%. Goodyear (now Loral) is the current manufacturer. Mk 30 was approved for service use in 1978.

In 1976 the total stated requirement was 260, but this fell to 60 Mk 30 Mod 1 by 1981, the estimated unit cost then being \$2.7M (FY82). The goal of 60 units by FY86 assumes 2400 runs per year.

Mk 30 is used by the 3 main underwater ranges: Barking Sands in Hawaii, AUTEC in the Bahamas, and the Atlantic Fleet range at St. Croix in the Virgin Islands.

The next version will be Mod 3, which is part of the Advanced ASW Target program. Mk 30 Mod 3 uses the acoustic signal processor, power amplifier, and towed array previously under development for Mod 2, the guidance and control of the current Mod 1, and Mk 48 ADCAPS propulsion (selected in FY88). De-

development of the Mod 2 development target has been deferred to FY91.

The Advanced ASW Target program embraces 3 parallel programs: the Fast Deep Prototype Target (a 21-in vehicle, for Mk 48 and Mk 50 torpedoes), the Advanced ASW Target (6 Mk 30 Mod 3), and the Mk 39 EMATT.

Electro-acoustic mock-up testing of the Fast Deep Prototype was completed during FY88, and the towed array was delivered that year. In-water tests began in FY89.

◆ Mk 32

This fixed torpedo target, for Mk 37, 44, and 46 torpedoes, is suspended in the water at a preselected depth down to 500 ft (chosen in 50-ft increments). It can be used with an SQQ-18A sonar transponder, suspended at 50-ft depth; the latter provides returns for surface-ship sonars. Total weight is 95 lb.

◆ Mk 36

The towed underwater target consists of a large sonar reflector for Mk 48 torpedoes. The barge is 74 × 28 ft (95 tons), and the suspended target is 34 × 8.5 ft (22 tons). These figures explain the need for sophisticated signal processors and transmitters in much smaller torpedo-sized targets such as Mk 30 and Mk 40.

◆ Mk 38 (MMT)

The expendable mobile underwater target (mini-mobile target) is for SQS-23 and -26 sonars and for Mk 46 torpedoes. It is hand-launched, battery-powered, and free-running, with a maximum speed of 5 kt. Dimensions are 3.5 in × 4 ft (weight 20 lb); the manufacturer is Bunker-Ramo. Unit cost was \$1833 in FY81. This device is being replaced by Mk 39.

◆ EMATT (Mk 39)

Expendable Mobile ASW Training Target is an air- or ship-launched submarine simulator manufactured by Sippican for the Naval Sea Systems Command. The vehicle is the size of an A-size sonobuoy (4½ × 36 in) and weighs 21.1 lb. Run speed is 10 kt (duration 3 hr), and maximum depth is 700 ft. EMATT acts as an echo reporter for active sonars, produces signals for passive sonars, and acts as a transponder for the Mk 46 torpedo. EMATT can also deploy a 100-ft wire to produce a recognizable MAD signature.

Compared to its predecessor, the mini-mobile target (MMT, Mk 38), EMATT has increased dynamic capability, programmed run capability, acoustic compatibility with all fleet surface-ship and air platform sonars and sonobuoys, and capability for MAD simulation. EMATT provides an air-launch capability, which the current MMT Mk 38 lacks. It also provides a programmed run rather than the random course followed by Mk 38.

◆ ADMATT (EX-40)

Advanced Mobile Acoustic Torpedo Target is a modified Mk 45 torpedo hull that tows 1 of 2 acoustic arrays (100 and 380 ft long). Mod 1 has an additional 8-in section inserted between its nose and forebody, to accommodate a new processor; it has different arrays compatible with the new processor.

◆ EX-41

Advanced mobile ASW target. This program began in FY79 to replace existing Mk 30 Mod 1 and Mk 27 Mod 0 mobile underwater targets.

◆ SAWS

Submarine Acoustic Warfare System is a family of submarine systems that detect, classify, and track sonar and torpedo signals and jam or deceive those threats. Sonars are detected by WLR-9/12/17; torpedoes are detected and tracked by BLR-14/14A. There is also a special-purpose signal-tracking receiver. The system employs both a hull-mounted jammer (GNATS/NAU) and 3 families of decoys.

The decoys are 3-in devices (ADC Mk 2 Mods 0 and 1 and the NAE Beacon Mk 3 sonar countermeasure), 5-in devices

(ADC Mk 1 Mod 0), and 10-in devices (MOSS Mk 57). Of the 3, only the Mk 57 is mobile; it is a dual-purpose sonar and torpedo countermeasure, intended to simulate a full-size submarine.

Decoys were originally all of 3-in diameter, intended for launch from a modified signal ejector fed from inside the pressure hull. This ejector also fires the standard depth/temperature probes (SSXBT/SSXUI/SSXVT). CSA Mk 1, described above, is a 6-in external launcher. MOSS is fired quietly from a Mk 136 launcher, an insert in a standard 21-in tube. This device was probably introduced about 1973. It weighs about 1000 lb and can be jettisoned (through the muzzle of the tube) by water pulse.

Current efforts:

New Sonar Intercept System (NSIS) Operational Requirement (OR) was written in FY89, and that year specifications for an advanced development model (ADM) were begun. Installation and test on SSN 756 was planned for FY90. The Tentative Operational Requirement (TOR) was issued in September 1985, the Development Options Paper in September 1986, and the draft OR in September 1986.

Countermeasures Command and Control Unit (C/M CCU) This program was scheduled to begin in FY90. The Tentative Operational Requirement was issued in March 1986, followed by a Development Options Paper (DOP) in November 1987 and a draft OR in February 1988.

Sonobuoy Countermeasures This program began in FY90, and an advanced development model (ADM) is scheduled for fabrication in FY91. The TOR was issued in March 1986, followed by a DOP in November 1987 and a draft OR in February 1988.

Multi-Mode Device (MMD) An advanced development model (ADM) is to be fabricated in FY91. The TOR was issued in March 1986, followed by a DOP in November 1987 and by a draft OR in February 1988.

Submarine Torpedo Defense Weapon (SMTD) Work is to begin in FY91. Some of the exotic devices described under SSTD may be intended primarily for submarine defense. The TOR was issued in March 1986, the DOP in November 1987, and the draft OR in February 1988.

Countermeasures Torpedo Tube Launching System/Quiet Launcher (CTTLS/QLHNR) This, rather than the exotic vehicles, may be the electromagnetic launcher mentioned under SSTD. The TOR was issued in March 1986, the DOP in November 1987, and the draft OR in February 1988. The quiet electromagnetic launcher is to be fabricated in FY90, subjected to laboratory test in FY91, and passed to development in FY92.

◆ SPAT

Self-Propelled Acoustic Target is a torpedo-sized submarine simulator manufactured by Westinghouse (formerly Gould). Although normally considered a training device, SPAT might also be considered a long-lived decoy. The vehicle carries an echo repeater (4–85 kHz, pulse width 1 msec–1 sec, PRI ½ sec or more), which it tows on a 12-m coaxial cable. The echo repeater is programmable to provide a target size from 13–25 dB. The echo contains highlights, elongation, and a self-doppler. There is also a broad-band noise generator simulating a submarine (800 Hz–85 kHz). Total radiated power is at least 160 dB (re 1 micro-Pascal at 1 m). Run geometry (including snake, circular, and spiral patterns) can be programmed from the FCS launching SPAT or called up from the vehicle's preprogrammed memory. Total run time is 2 hr. Maximum speed is 11–13 kt (for up to 10 min), and cruising speed is 6–8 kt. Dimensions are 10 × 129 in; weight is 330 lb; depth limits are 16–787 ft; maximum dive/climb angle is 15 deg.

SPAT entered production about 1980. It was based in part on experience with an earlier submarine countermeasure, the BLQ-2 beacon of the 1950s.

◆ Mobile Submarine Simulator (MOSS)

MOSS is the Mk 57 10-in simulator, fired by the Mk 70 fire-control and launching system, primarily for strategic submarines. The catapult launcher is fired from a submarine torpedo tube. Each Trident submarine is to carry 2 launchers and 6 MOSSs; each Poseidon carries 1 launcher and 4 MOSSs. Attack submarines carry 1 launcher and 4 MOSSs. As of FY79, the navy inventory objective, not including Trident units, was 213 MOSSs, 134 for shipfills, 84 for the pipeline, and 7 for navy schools. These purchases covered only strategic submarines.

MOSS was in advanced development in 1973, and proof tests of 26 were completed by the end of FY76. Initial operational test and evaluation was completed in September 1976, and provisional approval for service use was granted in June 1979. Gould received an initial production contract for 36 simulators in August 1977. The FY78 program provided for 56, and the FY79 program for 65 more. The FY79 purchase was halved by Congress because the system was not yet mature, but purchases were later resumed.

MINE WARFARE

This section includes both mines (antiship and antisubmarine) and mine countermeasures. Mines in current service include some types developed as long ago as World War I, and the influence explosion mechanisms developed during World War II still seem to dominate the field. It is difficult to say which old types remain in service; for example, the United States reportedly distributed Mk 6 moored antenna mines to many allies after World War II.

The major current mine mechanisms are contact, acoustic, magnetic, and pressure, although others may exist. The simplest contact mines are set off by an electric current produced when a ship breaks open the batteries formed in the "horns" of the mine. The U.S. Mk 6 of World War I was a more sophisticated alternative: a ship touching or nearing an antenna formed 1 element of a simple battery, closing a firing circuit. The advantage of an antenna is that it greatly increased the lethal radius of the mine. In this way a submerged mine could destroy submarines passing well above or below it, at distances sufficient to block the band of depth available to World War I (but not modern) submarines.

The other major mine types are described as influence weapons, exploding at a distance from a ship. Influence mines on the seabed were the first weapons attacking ships from under the keel.

An acoustic mine listens for the characteristic signature of its target. World War II acoustic mines simply listened for an increase in broad-band sound, but it should be possible to set a modern acoustic mine for a particular characteristic frequency or set of frequencies.

Magnetic mines detect the magnetism of a ship's steel. The early magnetic mines had to rest on the sea bottom, but after World War II the U.S. Navy developed a new 3-axis magnetometer that could compensate for the tidal movement of a moored mine.

Pressure mines respond to the decrease in water pressure under a ship. Such mines necessarily lie on the bottom, and they must be protected against mistaking the change due to the turn of the tide for the change due to the passage of a ship. One solution is to combine the pressure sensor with 1 or more sensors of the target's characteristics (e.g., acoustic or magnetic), so as to eliminate the problem.

Contact mines must generally be moored. The main limitation on their design is the requirement that the combination of mine body and mooring chain be buoyant. The weight of the mooring chain limits the potential weight of explosive. For example, some have suggested that Iranian contact (moored) mines in the Persian Gulf often broke their moorings because the Iranians tried to load them too heavily and used chain that was too weak. Acoustic and magnetic mines may be moored, or they may sit on the bottom. Generally, a bottom mine can be effective in depths as great as 80 ft. Presumably, mines can lie in greater depths if they are intended to damage very large merchant ships, which may draw that much water.

There is a difference between a mine's case depth and laying depth. Case depth is the depth at which the mine itself lies or floats. A floating mine will have an anchor at a far greater depth, which will be the laying depth.

Pressure mines are inevitably bottom mines since they measure the absolute drop in pressure associated with the difference between water depth and the depth of water under a ship. Thus they are only an inshore hazard.

For very deep water, there is a further category, the rising mine. The mine case may lie close to the bottom, but when it detects a passing ship or submarine it launches a projectile or torpedo. The U.S. Captor (Mk 60) is the best known, but not the only, example. Depending upon the speed and endurance of the projectile, a rising mine may be laid in extremely deep water. Moreover, it may be able to hit a target at some distance. That capability requires a long-range sensor unlike that used in any other mine category.

The only available sensor is an acoustic one. A bottom mine must rely on passive detection of its target, recognizing the

target's signature. The mine then uses an active acoustic sensor for fire control. In principle, then, deep rising mines can generally be countered either by silencing (which denies them the initial detection) or by some form of active deception (which ruins the fire-control solution). However, the mine, even if it is quite deep, is probably functioning far closer to its target (e.g., within about a thousand feet) than any sonar (and far closer than virtually any sonobuoy), so the mine may be able to rely on an HF signature that is lost at normal ASW ranges.

As an example of such a mine, Captor relies on a long-range passive sonar for initial detection and then on a long-range active sonar for target tracking. Presumably, this mine requires the long-range initial detection for 2 reasons. First, there is a substantial time lag between the weapon's launch and the weapon's arrival near the target, so the target has to be detected early. Second, because the torpedo can maneuver as it rises, the mine can engage fairly distant targets, if it can detect them. In contrast, an unguided rocket mine (such as the abortive U.S. PRAM or, probably, the Soviet Cluster Bay/Gulf) travels straight up. Its required detection range is set by the time to rise and by the decision time required to classify the target. Such a weapon cannot rely on any kind of impact fuze because the projectile may be near, but not at, the target. Instead, the active sonar is probably used to fuze the projectile.

A rising mine's case depth is probably fixed by the crush depths of the mechanism and the projectile. In really deep water, then, the mine must be moored, and its case must be buoyant enough to support a considerable weight of cable. Consequently, the mine must be large, and the laying rate will be limited. In contrast, in shallower water, say down to a thousand feet or more, the mine case might well lie on the bottom, unsweepable by mechanical means (i.e., by any device that would cut the mooring cable). Very deep minehunting sonars, such as are now being developed, are presumably intended to detect just such bottom mines.

The effect of the existence of deep-water rising mines is to extend the mineable area of the world significantly. Countermeasures are very expensive because the mine may cover a substantial lethal area (the projectile may maneuver to 1 side or the other) and because any attempt to destroy mines or mine mooring requires very deep operations. Examples of such expensive countermeasures probably include not only the British EDATS but also the U.S. Mine Neutralization System. However, because bottom mines must use passive acoustic detectors, these mines are (at least in theory) subject to sweep by acoustic devices simulating target signatures.

There are several mine countermeasures, in 2 categories. One is self-protection, for a ship passing through an area that may be mined. The other is mine clearance, either sweeping (wholesale mine neutralization) or minehunting. In the latter, the bottom is examined foot by foot, and suspicious objects are examined and, if they are mines, destroyed individually. Sweeping means either cutting mine-mooring cables (and thus bringing the mines to the surface, where they can be destroyed by small-arms fire) or providing a false signature that causes influence mines to detonate without damaging real targets. Minehunting is necessary because some mines, such as pressure types, cannot be induced to explode by anything short of a real ship since the signatures in question cannot be duplicated.

When virtually all mines were contact weapons, the chief self-protection measure was the paravane, a towed float whose wire pushed moored mines away from the ship. Paravanes were standard in both world wars but were largely abandoned with the advent of large bow sonar domes (which paravanes could damage) and also with the advent of influence mines (which paravanes could not counter). The only modern self-protection measures are silencing (against acoustic mines) and degaussing (in effect, magnetic silencing). The only protection against pressure mines is to move so slowly that the pressure change is not quick enough to detonate the mine. In World War II, for example, tables were constructed to show appropriate speeds for ships of particular tonnages.

Most current mine-countermeasures work goes into sweeping and hunting. Moored mines may be swept by means of a cable carrying small explosive-driven cutters. Moored or bottom acoustic and magnetic mines are generally swept by towed acoustic or magnetic noisemakers. Mine designers have produced 2 counter-countermeasures. One is a ship counter, which allows several potential targets to pass before the mine is armed. The ship counter was invented by the Germans during World War II, and by 1944 many mines could let at least 15 targets pass before exploding. In theory, a counter protects the mine against sweepers accompanying a high-value target. A second counter-countermeasure is arming delay, which appears in many of the mine descriptions below. The presence of delay-armed mines forces influence sweepers to go back over a field. This idea also applies to moored mines, for which the mine's release from its anchor can be delayed.

Many current mines are described as microprocessor-controlled. They can be programmed to seek particular ship signatures, are extended in space (i.e., in time, as the ship passes over), and so will force the minesweeper to use more and more complex ship simulators. The British Sea Serpent and the French Sterne I exemplify the counters to this type of mine. Compared to earlier hard-wired mine sensors, a microprocessor can very easily be reset to any desired set of target characteristics or counter-countermeasures.

Pressure mines cannot easily be swept. If they distinguish between the turn of the tide and a ship by using a known auxiliary (acoustic or magnetic) sensor, they should be vulnerable to an appropriate towed noisemaker. However, that relatively desperate measure is much dependent on detailed knowledge of the threat mine. In any case, a pure pressure mine can be designed to avoid detonating at the turn of the tide.

Minehunting employs a high-definition (VHF) sonar to identify suspicious objects, and then some means of examining and destroying those objects. The simplest such system employs divers, but modern Western navies tend to employ remotely controlled submersibles equipped with even higher definition sonar and underwater television (such as PAP 104 or the Honeywell MNS) instead. The great problem of hunting is that most harbor bottoms are covered by the detritus of industry (cars, refrigerators, bodies in concrete, etc.), much of it vaguely resembling mines (which need not be neatly packaged as cylinders with markings like "Mine—do not handle"). The very high false-target rate explains the need to examine each suspicious object, rather than destroying it immediately from the minehunter. To the extent that friendly harbors must be protected against mining, detailed bottom surveys of the routes merchant ships are expected to take can be used for comparison, to find out which suspicious objects are new.

Even then, there is a serious problem in silty harbors, as mines dropped on the bottom tend to bury themselves. Depending on their trigger mechanisms, they may still be lethal in that state. This problem probably applies more to magnetic than to other mine mechanisms.

Mine-countermeasures vessels tend to be small because their small signatures tend not to set off influence mines and because sweepers and hunters are needed in substantial numbers and, therefore, cannot be allowed to grow too expensive. If they are built on conventional lines, then, these craft are relatively slow. They may be effective in home waters, but they cannot easily deploy with the fleet. If territorial waters are extensive, moreover, and if the sweepers are expensive (because they have to be sophisticated), then their low speed may be a problem even at home. Norway faces this problem, for example, and it explains current Norwegian interest in surface-effect minesweepers. An alternative is to develop a mine-countermeasure suite that can be fitted to extemporized craft of opportunity, but it seems less and less likely that any such craft will be quiet enough (acoustically or magnetically) to avoid setting off special antisweeper inshore weapons. One alternative, adopted by the U.S. Navy, is the helicopter sweeper or hunter. Helicopters can be carried abroad with the fleet, and they can tow special sweeps

for hunting sonars. They are clearly limited, but they make up for that limitation with extreme mobility. Experience in the Persian Gulf seems to show that conventional surface sweepers and hunters are, of course, still essential.

Small remotely controlled submersibles are commonly used by the offshore oil drilling industry. Most of these devices may be too small to carry useful mine-disposal charges (or, for that matter, useful mine-classification sensors), but these submersibles may be usable under mobilization conditions. In 1985 Gould marketed 1 such a vehicle, the Sea Rover, in the United States; it was small enough to travel as excess luggage on most airlines. The vehicle itself weighed 45–55 lb.

Many mines of pre- or World War II origin probably remain. The section that follows lists only the older Soviet and U.S. weapons, but before World War II France (Breguet and Sauter-Harle), Norway, and Sweden all produced a variety of contact mines, and, in some cases, influence mines. Some probably still exist. Vickers produced a variety of commercial mines, some of which were reported in Argentine service during the Falklands War. Some wartime German mines may have survived, as German wartime coast-defense guns have. Similarly, Japanese contact mines may have survived in the Far East. The key point is that mines, particularly contact mines, do not become obsolete. No details of which weapons are used by which navies are available. Similarly, no details of controlled mines, used for harbor defense, have appeared, apart from the data below concerning the U.S. Mk 51. It is unlikely to be unique. Finally, U.S. mine exports almost certainly included plans and production assistance, so that various countries have manufactured U.S. mines (perhaps in modified form) under local designations.

The United States supplied specially converted minelayers (and, presumably, mines) to Denmark, Greece, Norway, and Turkey during the mid-1950s, before the Mk 52 series entered full production. The principal available surface-laid mines were, then, probably Mk 6, Mk 16, and Mk 18.

MINES

Navies rarely indicate their own capacity for naval mine warfare. In 1988 the U.S. Office of Naval Intelligence stated that 21 countries could deploy mines capable of damaging major warships. In the Falklands, Argentina was credited with a serious mining capability, although it appears that she did not make use of it. In the past, the United States has provided allies near strategic straits with minelaying ships and, presumably, with U.S. mines.

CHILE

Cardoen Industries produces a clone of the British Marconi Stonefish. In August 1990 it was reported that some of these mines had been exported to Iraq.

◆ MS-L/MS-C

These are magnetic ground mines made by FAMAE (Fabricas & Maestranzas de Ejercito); MS-C is a shorter (1425- rather than 2060-mm) version of MS-L, with the same internal design and the same mechanism. Both are torpedo-tube size (534.416 mm in diameter); the smaller mine is intended for air-laying against landing craft. The fuze seeks a sufficiently large change in polarity (through zero), within a set time window, to reject fields that vary either too slowly or too rapidly (e.g., to reject a magnetic object moving too slowly or too fast). The programmable parameters are the following: magnetometer sensitivity (2, 4, 8, 16, 32 mGauss), fuze arming time (2, 4, 16, 32, 64, 128, 256, 512 hr), inhibition time (32, 256, 512 sec), lower limit window time (2 or 4 sec), upper limit window time (16, 32, 64 sec), ship counter (1–9), and sterilization time (2, 4, 8, 16, 32, 64 weeks). Inhibition time is a delay after the fuze has accepted a target as real, to protect the mine against multiple magnetic sweeps in combination.

DENMARK

◆ MTP-19

This new controlled mine, entering service with the Royal Danish Navy, was first displayed at Defendory in October 1990. It is made by NEA Lindberg. MTP-19 is launched by means of a trolley, the wheels of which fit the train rails in Danish ferries (which would be the primary minelayers in an emergency). The mine has 2 sections, the mine case proper (the 300-kg charge and a microcomputer) and the flotation unit. Because the flotation unit, carrying the mine-control cable, rises to the surface for retrieval soon after the mine is laid, connection to the control cable is relatively easy; several mines can be linked to a single distribution box. Operation is either under full control (which can be automatic, using a shore-based sensor) or auto-alarm (the mine uses its own sensors, based on criteria in its microprocessor). The normal operating depth is 20 m, and the mine can be controlled from up to 12 km away.

FRANCE

The principal prewar surface-laid mines were all contact types: the Breguet B4, B4M, and B5B, and the Sauter-Harle H5, H5P, and H6. The Breguets were relatively small horned mines, with total weights of 1168 lb (B4/B4M) and 2535 lb (B5); explosive weights were, respectively, 176 and 485 lb. B5B was an antenna ASW mine analogous to the U.S. Mk 6, with 25-m upper and 30-m lower antennae. These mines entered service in the late 1930s, the mines lying at a depth of 90 m [about 300 ft] with alternative water depths (mooring depths) of 225, 300, or 400 m [respectively, about 740, 1000, and 1310 ft]. The Sauter-Harles were antiship mines. H5 and H5P were horned mines (4 horns) with a total weight of about 2550 lb (485 lb of TNT). Some versions had antennae. These older mines were introduced in 1928. Prewar versions, which may have been experimental, were designed for greater depths (e.g., H5UM1, moored in about 3000 ft of water to float at 600 ft [1935]). H6 was a horned mine with a heavier explosive charge (about 660 lb of TNT). These mines apparently survived World War II, and some probably still exist.

Postwar, the French navy developed a wartime German project for a bottom mine triggered by cosmic radiation. In principle, the layer of water over the mine reduced the level of radiation by an amount proportional to its depth. The water under a ship would be less, so the radiation level would rise and the mine would be triggered. In theory, such operation would be analogous to that of a pressure mine. In practice, the problem was that levels of cosmic radiation fluctuated naturally, so the mine had to use an array of detectors to make instantaneous comparisons between the average radiation level and that immediately overhead. This concept was reportedly the main French mine research project of the mid-1950s; by that time the U.S. Navy had given up on the idea (which had been quite exciting about 5 yr earlier). No such mine appears to have entered service, and it seems likely that the cosmic-ray mine fell victim to the massive French research budget cuts associated with the Algerian War. The types described below were probably the only fruits of later French work.

◆ FG 29

FG 29 uses multi-influence sensors and is designed for localized laying from submarine torpedo tubes. Dimensions are 52 cm × 3 m, and weight is 1000 kg (600 kg of tritonal explosive). FG 29 can operate down to 300 m in depth. FG 29 has an arming delay, and it is an antisweep device, explosion-resistant to defeat explosion-based minesweeping. Fuzing is magnetic, acoustic, or pressure. This mine is very sensitive, so it can be used against ships with very low magnetic moments. The acoustic sensor operates on several LF channels. The main contractor is DCN; Thomson Sintra makes the sensors. The development of FG 29 began in the early 1970s, and the first batch was delivered to the French navy in 1988.

The earlier FG 18 was used on board *Daphne*-class submarines.

◆ TSM 3510 (MCC 23)

This magnetic/acoustic ground mine is designed to be triggered by any ship displacing over 1000 tons. TSM 3510 can be launched from a torpedo tube, so the diameter is 533.4 or 550 mm [21 or 21.7 in]; the length is 2.525 m [99.4 in]. Weight is 850 kg, including a 530-kg warhead [1873/1168 lb]. The mine can be set to wait for up to 30 days before arming, and there is a ship counter. Thomson Sintra is the manufacturer. An earlier version (ca. 1978) was 530 × 2368 mm [20.9 × 93.2 in], with a 650-kg [1432-lb] warhead.

There are also practice mines: a submarine-laid mine, EP 30C (533.4 mm × 3 m, 900 kg [21 × 118 in, 1984 lb]), which can be laid in depths of 10–50 m; and sweeper/laying training mines, ED 28B (TSM 3500) and MCED 23 (TSM 3517)/MCEM 23 (TSM 3515). The latter is intended to train minelayers, and it lacks the magnetic and acoustic detonator scoring system of the former. ED 28 is laid by surface vessels.

Thomson-CSF began work on mines in the late 1960s, beginning with exercise mines for surface ships and submarines.

◆ TSM 3530 (MCT 15)

MCC 23 (above) and MCT 15 (below). (Thomson Sintra)

TSM 3530 is an air-dropped, parachute-retarded mine. Dimensions are 1.2 (diameter) × 1.1 m [47.2 × 43.3 in]; weight is 1500 kg, including a 1000-kg warhead [3306/2204 lb]. Fuzing is acoustic/magnetic. 3530 is almost semispherical in shape. Like MCC 23, 3530 arms after a clock-set delay. Thomson Sintra is the manufacturer.

GERMANY (WEST)

The postwar German navy used stocks of wartime and postwar mines, presumably of U.S. and British origin. A new generation of ground and moored mines (and antisweep devices) was developed under a Seemine 65 program. It resulted in the FG 1 described below. Germany and Denmark collaborated in 2 more recent programs, Seegrundmine 80 (SGM 80) and Seemine Anti-Invasion (SAI).

German World War II mines were all designated by letters, the first 2 indicating the function and the third the type within that category. The EM series (e.g., EMC) were horned contact mines, EMC and EMD being the most common. The KM series were anti-invasion mines, typically with a single horn protruding. RM indicated a controlled mine. UM mines were ASW contact weapons. There were also mines for torpedo-tube laying (MT and TM series) and for air laying (BM and LM series), but these are unlikely to have been suited to the requirements of current users. Likely users of German prewar and World War II mines would include Finland (which was a German ally during much of World War II, and which received little military hardware postwar), Spain (which would have received considerable aid during the civil war and afterward, and which operated some German submarines, torpedo boats, and aircraft), and Yugoslavia (which retains a few German coast-defense guns).

◆ FG 1

This submarine-launched ground mine is built of nonmagnetic material, with a 535-kg [1179-lb] warhead. Dimensions are 534 mm × 2310 mm: 710 mm for the control section, 1600 mm for the charge section [21 × 91 in: 28 in/63 in]. Total weight is 770.5 kg [1698 lb]. Maximum effective depth is 60 m [197 ft]. FG 1 is built by the Faun-Werke.

◆ G2 (SGM 80/IGM 10)

This cylindrical ground mine was developed for launch from a cradle on board a fast attack craft. The joint Danish-German program began in 1980 (hence the Seegrundmine 80, or SGM 80, designation initially applied). Development was completed in 1986, with approval for service use in July. Although Dornier had built prototypes, KAE was awarded the production contract in 1987, and tests were completed at the end of 1989. The initial requirement emphasized minimum dimensions and weight, maximum flexibility in target selection (with simplified setting), antisabotage and antisweep features, and minimum maintenance. The explosive and nonexplosive parts of the mine are separate, coupled by a clamping ring, with the safing and arming device in the explosive section. The programmable microprocessor has acoustic, magnetic, and hydrodynamic signal-processing channels, which may be used either individually or in combination. Surveillance sensors are used to filter out environmental effects, such as tides. The microprocessor program is divided into constant data (basic algorithms and signal-

SGM 80. (Dornier)

processing techniques) and mission data (preferred targets, choice of sensor combination, arming delay, ship count, etc.).

A separate data-acquisition (measurement) version of the mine can be used to obtain the signatures of potential targets, e.g., on a test range. An operational mine contains a library of such signatures, corrected for environmental conditions at the point of measurement; it arms when a received signature matches the appropriate library signature. The multiple sensors are used to estimate the range to the target, and the mine explodes when its target comes within optimum range (for that type of target, as estimated from damage curves).

There is also an exercise version.

G2 is expected to require inspection every 4 yr, at which time operational inputs are fed into the microprocessor.

IGM 10 is a G2/SGM 80 derivative, to be laid by submarines with external mine belts. It can be laid in deep water. Like G2, IGM 10 has a programmable microprocessor using acoustic (low and audio frequency), magnetic, pressure, or a combination of signatures. IGM 10 can be programmed immediately before leaving the ammunition depot.

◆ G3

This sea mine, now in the concept phase, is to neutralize new types of targets, such as surface-effect ships.

◆ SAI

Seemine Anti-Invasion, another Danish-German project, is to be laid by landing craft. It was procured in 1982–90.

IRAQ

Iraq displayed 3 mines at the Baghdad military show in 1989.

◆ Al-Muthena/35

Total weight 190 kg (84-kg mine and 105-kg sinker), with a 35-kg explosive charge. This is a contact mine to damage floating pontoons, bridges, and shallow-draft craft. It uses either electromechanical horns or an electronic timer. Total height is 980 mm, of which 610 mm is the mine proper [38.6/24.0 in], and diameter is 550 mm [21.7 in].

◆ Al-Muthena/45

95-kg mine (45-kg explosive), using electromechanical contact horns or timer. It has 6 horns, laterally spaced, like the spokes of a wheel, in 1 row. Dimensions: 555 mm dia × 660 mm high [21.9 × 26.0 in].

◆ Sigeel/400

A ship- or helicopter-laid bottom mine, in the form of a truncated cone with additional mechanism on top. Weight: 535 kg (400 kg of TNT). Dimensions: lower diameter 980 mm, upper diameter 700 mm [38.6/27.6 in] × 850 mm, of which the mine proper is 610 mm [33.5/24.0 in].

ITALY

The principal mine manufacturer, Misar, was formed in 1977 by a group of technicians who joined the Italian SEI (Società Esplosivi Industriali) and the French SAEPC (Société Anonyme d'Explosifs et des Produits Chimiques) to develop and sell both naval and land mines.

◆ EPR Series

Tecnovar's anti-invasion mines are essentially flat disks (like land antitank mines) in form. The number indicates the weight of explosive, 1.2, 3.6, or 6 kg (e.g., EPR 3.6). Fuzing is electronic.

These mines were announced about 1981.

An EPR 2.5 limpet mine advertised in 1984 weighed about 6 kg [13 lb] and carried a 2.5-kg [5.5-lb] charge. EPR 2.5 was described as an electronic underwater mine, which might be laid by aircraft or else magnetically/mechanically attached to the hull of a ship. Dimensions: 26-cm diameter × 9-cm height [10.2 × 3.5 in]. In tests, EPR 2.5 blew a 250-mm [9.8-in] diameter hole in a steel plate 30 mm [1.2 in] thick.

◆ MAL/17 and MAS/22

Tecnovar's anti-invasion mine was advertised in 1984. MAL/17 is a contact mine with 3 horns in its top and a stabilizer extending down from its spherical body. Total weight is 22 kg, and it carries a 17-kg charge [48.5/37.5 lb]. Dimensions: 38-cm diameter, 110-cm height, including stabilizer [15 in × 4.3 in]. Case depth is about 3 m [10 ft].

MAS/22 is an alternative version of the same mine, with 3 sharp stakes at its bottom so that it can be driven into a beach (just below the water line) or into a river bed. Total weight is about 22 kg, and charge weight is about 17 kg. MAS/22 is hemispherical (virtually identical to the upper hemisphere of MAL/17), with a diameter of 38 cm and a height (including spikes) of 63 cm [24.8 in].

Tecnovar mines (left to right): MAL/17, MAS/22, and EPR 2.5. (Tecnovar)

◆ MANTA

Misar's anti-invasion (shallow water) mine, for depths of 2.5–100 m [8–330 ft], has an effective lifetime of over a year. It uses magnetic and acoustic fuzes and can be laid by ships, helicopters, or frogmen. The warhead is 140 kg of TNT or 170 kg of HBX-3 [309 or 375 lb]. Dimensions: diameter 980 mm, height 470 mm [38.6 × 18.5 in]. Total weight is about 220 kg or 240 kg depending on loading [485 or 529 lb]. The form of the casing is intended both to avoid movement due to currents and to avoid visual detection. Manta's shelf life is 30 yr, and the mine will operate for 17 months when laid.

Manta, with MRP-80 in the background. (Misar)

◆ MR-80/MP-80/MRP

Misar's antiship and antisubmarine mine is usable in depths of 5–300 m [15–100 ft], with a maximum transport depth of 500 m [1640 ft] and a submerged life of up to 2 yr. There are 3

versions, A, B, and C. Characteristics are as follows:

	A	B	C
Dimensions	533 × 1650 mm [21 × 65 in]	533 × 2096 mm [21 × 83 in]	533 × 2750 mm [21 × 108 in]
Total Weight	656 kg [1446 lb]	820 kg [1807 lb]	1070 kg [2358 lb]
Explosive	460 kg [1014 lb]	630 kg [1389 lb]	870 kg [1917 lb]

Available fuzes are magnetic, pressure, and acoustic (HF or LF), and they can be used in any desired combination. Arming and neutralization delays can be set at up to 999 days, for a useful life of 500–1000 days. MR-80 can be laid by torpedo tube but also by aircraft or surface ship. The casing is made of fiberglass impregnated with epoxy resin, carrying explosives in the nose and the controls in the tail.

Reportedly, MR-80 has been sold to several Middle East countries.

MP-80/MRP is a similar mine with an updated firing mechanism and a better (digital) target recognition device. This mine has 4 microprocessors, which compare the target's signature (magnetic, pressure, and/or acoustic) with entries in a threat library: thus, mines can almost be assigned to particular targets. MP-80 is the Italian navy/NATO version; MRP, with software not subject to NATO restrictions, is the export version (Misar's Advanced General-Purpose Sea Mine).

The initial MR-80/1, announced in 1978, was the first Misar mine. It could be laid in water 10–200 m [33–660 ft] deep. In 1978 it was being evaluated by the Italian navy, probably as an alternative to the Valtec SM 600; it seems to have been the successful competitor. MRP's dimensions: 533 × 2096 mm [21 × 82.5 in]; weight: 800 kg (620-kg HBX-1 explosive). Mechanical, structural, and explosive features match those of MR-80/B.

MR-80/I and MRP/I are training and trials variants of MR-80 and MRP.

About 1986, at the request of the Italian navy, Misar conducted a feasibility study of the modernization of Italian stocks of U.S. mines (Mk 13 Mod 6, Mk 52). The conclusion, that the mines themselves were in good condition but that their firing mechanisms needed replacement, led the company to study the export market for such modernization. Presumably, this program competes with the British Aerospace modernization programs described under the United Kingdom entries below.

In mid-1985 Misar signed an agreement with Aerojet to market the U.S. Mk 65 Quickstrike mine with a Misar Target Detection Device (TDD) related to that of the MP-80/MRP.

◆ SB-33

Misar's antisaboteur mine can be used either on land or against divers (fuzed by pressure, to explode at a preset depth) or as a submarine signal. Like SB-81 (below), it can be supplied in a magazine suitable for scattering from a vehicle or a helicopter. Dimensions: 88 × 32 mm. Weight: 140 g (charge 34 g).

◆ SB-81

Misar's coastal mine/depth charge/countermining charge has a weight of 3.2 kg (2-kg charge) and can shear a 35-mm steel plate. Dimensions: 232 × 90 mm. It explodes by pressure, at a preset depth. For coast defense it is mechanically fuzed. Misar manufactures an SB-81 magazine adapted to mine scattering by helicopter (the SY-AT system).

◆ SB-MV/1

Misar's shaped-charge anti-invasion mine was displayed in 1980. It weighs 5 kg (2.6-kg charge) and can penetrate 150 mm of armor at a distance of 600 mm; Misar claims that it is 3 times as effective as a more conventional mine. It is intended to attack amphibious vehicles at the water's edge.

Misar also produces an "extended range" mine, P40, which projects a charge at a sensed target.

◆ TAR 6/TAR 16

These multicharge (string) ASW mines are made by Whitehead. TAR 6 can be used against surface targets and is intended to bar passage from the surface down to a depth as great as 820 ft. A typical barrier consists of 4 rows of mines carrying their vertical strings of charges at different depths; the numbers in TAR 6 and 16 are the number of charges. Each charge carries 3 switch (not chemical) horns. Because the detonation of any 1 charge in the string generally sets off the others, a single string cannot effectively cover the entire depth to be blocked.

TAR 6 consists of a buoy, itself carrying a charge, 5 cylindrical charges, and an anchor, the charges being spaced about 13 ft apart. Thus a buoy at a depth of 16 ft carries a string that reaches down to 92 ft. The buoy carries 110 lb of explosives, and each cylinder carries another 55 lb. TAR 16 is similar, except that it has more charges and its buoy is not explosive. TAR 16 covers a total length of 225 ft, the buoy floating 39 ft above the shallowest charge. A typical field might consist of a row of TAR 6s, their deepest charges at 92 ft, then a row of TAR 16s, with buoys at 65 ft and charges extending down to 330 ft, then another row of TAR 16s (buoys at 65 ft, but shallowest charges at 348 ft and deepest at 572 ft), and then a third row of TAR 16s (buoy at 65 ft, charges between 590 and 812 ft).

Typical assembled dimensions of TAR 6 are 6 ft 5.5 in (high) × 3 ft 6 in (wide) × 3 ft 11 in. Weight is 2435 lb. Analogous figures for TAR 16 are 7 ft 6.5 in × 3 ft 8 in × 3 ft 11 in and 3240 lb. TAR 16 can be laid in water depths as great as 1520 ft.

TAR means *Torpedine Antisom Rosario*, or antisubmarine rosary mine. It was conceived in the early 1950s, and by October 1954 test fields had been planted in depths as great as 400 ft.

◆ VS-RM-22 and -30

Valtec's anti-invasion or shallow-water mines are exploded by trip-wire. The number indicates the weight in kg.

◆ VS-SM-600

Valtec's ground mine can be laid in water 10–150 m deep [33 to 490 ft] by a surface ship, a submarine, or an airplane. The 4 sensors are magnetic, HF acoustic, LF acoustic, and pressure. There are also a ship counter, an antitamper device, and a long arming delay. The mine can be remotely controlled. Dimensions are 533 mm × 2.75 m [21 × 108 in]. Weight is 780 kg [1719 lb], with a 600-kg [1322-lb] charge.

◆ VS-SS-22 and -30

VS-SS-22, a limpet mine made by Valtec, is intended to sink ships of up to 400 tons and to disable ships up to 4 times that size. -22 carries about 12 kg of RDX/A10 explosive. The mine is attached to its target by 2 rubber suckers, by 2 pins driven in by rivet guns, or by a removable clamp. Dimensions are 200 × 650 × 360 mm [7.9 × 25.6 × 14.2 in]. Weight is 20 kg, including 10 kg of explosives [44/22 lb], and the standard arming delay is 15 min, after which antihandling devices switch on. The explosion delay can be between 1 and 10 hr.

◆ WP 900

Whitehead's modular ground influence mine is laid by submarine or surface ship. There are 3 versions, containing 1, 2, or 3 charges; and fuzing can be a combination of magnetic, acoustic, and pressure. Designed shelf life is 30 yr.

WP/E 900 is an exercise version.

◆ New Mine Projects

Three new Misar mine projects were shown at the Mostra Navale show in May 1989. Seppia is a private-venture moored multi-influence mine, using a Misar-developed programmable microprocessor. It is an 870-kg cylindrical mine (it can be laid from torpedo tubes) carrying a 200-kg (HBX-1) explosive load, and it can be laid by ships, aircraft, or submarines. It uses the Misar TDD to control its operating depth (down to 300 m), fuze

sensitivities, the moment of firing (based on target classification), arming delay, life, and ship count.

Misar is also developing a moored mine, MEB 90, in a joint venture with 2 Spanish companies, Bazan and Expal. MEB 90 uses the Misar TDD and, like Seppia, MEB 90 can be moored in depths as great as 300 m [1000 ft].

Finally, the company is developing the CSM rising continental-shelf mine in collaboration with Whitehead, for the Italian navy. The rising body is described as partially self-guided.

JAPAN

The principal wartime moored mine was Type 93, which carried an explosive charge of 220 or 243 lb. Net buoyancy (which determined how much mooring cable could be used) was 265 or 43 lb (depending on explosive load), and total weight, including anchor, was 1543 or 1565 lb. Using thin cable, a Type 93 mine could be laid in water as deep as 586 fathoms (3250 ft). These mines were provided with 4, 7, or 9 contact (Hertz) horns. Stocks in Japan in 1945 were presumably destroyed, but stocks in Japanese-occupied territory probably survived the war.

Japan currently uses mines either identical to, or externally similar to, U.S. types. Japan's current mines are designated in a K-series during their development period, after which they receive Type numbers. The types are: K-1, K-2, K-3, K-4, K-5, K-13, K-15, K-16, K-21, K-22, K-23, K-24, K-52, and K-55. K-15 is the Type 56 moored contact (antenna) mine, similar to the U.S. Mk 6. K-21, K-22, K-23, and K-24 are Type 70 bottom influence mines similar in appearance to the U.S. Mk 36. K-33 is a moored contact mine. There is also a Type 55 horned moored mine (710 kg total, including 100 kg of TNT, with total buoyancy of 60 kg to support the mooring wire; diameter is 86 cm; there are 7 Hertz horns). The K-X moored mine, an air-dropped mine, and a rising mine are under development. The new air-dropped ground mine reached the hardware stage in 1989. The current R&D program includes a study of a minelaying system to be carried on board C-130H transport aircraft.

Reportedly, Mitsubishi is modernizing some Japanese mines, presumably those manufactured under U.S. license.

SPAIN

Inisel has manufactured the French MCC 23 under license. The Spanish navy also has 1500 Vickers-designed moored mines, which have been in storage since 1945. Expal, Inisel-Bazan, and Misar are currently competing to upgrade them.

Inisel and Chaconsa (which is responsible for the mine body, mechanism, and assembly) are developing a new MOM 90 moored mine, built of a Kevlar-like composite, using a glass-fiber mooring chain. It is to have an intelligent magnetic sensor and a "3D" acoustic sensor, with a low-sensitivity filling. Thomson-CSF is also involved in this project.

SOUTH AFRICA

South Africa manufactures a bottom mine based on British stonefish technology. In March 1990 it was reported that mines of this type had been sold to Libya.

Reportedly, Armscor modernizes some existing mines.

SWEDEN

◆ Bunny

Bofors's new submarine-laid bottom mine is laid from a saddle rather than a tube. It weighs 200 kg and uses the new 9SP180 sensor, described below, which is also being offered for mine upgrade programs. The saddle was developed by the German firm of Abeking & Rasmussen; it fits over the pressure hull of the submarine, laying its mines vertically. Tests have shown that it is compatible with current Swedish submarines, but none has yet been bought by Sweden.

◆ GMI 100 Rockan

This anti-invasion ground mine, for shallow water, was announced in 1984; Rockan can also be laid in deeper water as an

Rockan (left) and MMI 80 (right). (Bofors)

ASW mine. The unusual shape causes the mine to glide through the water, typically to twice the depth of the water in which the mine is laid (5–100-m depth). The mine's low profile makes sonar detection difficult, and the irregular shape and GRP casing tend to camouflage Rockan's purpose. Dimensions are 1015 × 800 × 385 mm; weight is 190 kg (105 kg of explosive); minimum distance between mines is 25 m.

The Rockan sensor will not react to any sweep that creates a homogeneous magnetic field; this sensor is also being incorporated into the moored MMI 80.

◆ LYDIA

This rising antiship mine was placed in production about 1956. LYDIA is laid as a bottom mine and is influence (passive acoustic) actuated. When it detects a ship, the mine rises by changing its buoyancy (its hydraulic mechanism pushes water out of the lower mine chamber). LYDIA then floats at a predetermined depth and is contact fired. If the sound source recedes without contact, the mine sinks to the bottom to await another ship, when it will again rise in a new cycle. Operational life is limited only by the battery (life 3 months, or about 60–90 cycles). Operation is limited to shallow water by the small negative buoyancy of the mine, which limits its resistance to currents and also limits the speed with which it can rise to meet a potential target.

◆ MMI 80

This moored influence mine, announced in 1984, has an operational depth of 20–200 m. The buoyant body is made of plastic, and the sensors are similar to those of the Rockan mine. Dimensions are 1125 × 660 × 1125 mm; total weight is 450 kg; charge is 80-kg hexotonal; sinker weight is 240 kg. Minimum distance between mines is 25 m.

◆ Mobile Mine

In 1985 it was announced that FFV, Bofors, and Ericsson were cooperating in the development of a submarine standoff mine, probably a converted torpedo. The principal changes would be a new influence sensor and a modified propulsion system for a long/slow rather than a short/fast run.

◆ SA Marine Mines

SA Marine manufactures a wide range of mines, details of which have not been published: modular ground mines (charges of 150–2400 kg), moored mines (charges of 80–200 kg, bottom depths of 30–500 m), and rising mines (both bottom-dormant moored mines and homing mines). The company also modernizes mines. The inclusion of homing mines in the company's advertisements suggests that the United States and the Soviet Union are not alone in possessing such weapons.

◆ Type 74

This moored mine is made by SAB Industri AB. Total weight is 205 kg, and the body is cylindrical. It can be laid in depths as great as 110 m and operates over a radius of 3–70 m.

◆ Type 77

SAB's pressure mine weighs 470 kg. It is to be laid in depths from 20–200 m.

◆ 9SP 180

BEAB's (formerly PEAB) mine sensor was announced in 1988 and carries a BEAB PHCS-1 (Philips Combined Hydrosensor) hydrosensor and a 3-axis magnetometer. The hydrosensor has separate channels for depth, dynamic pressure, and sound, and all of the signals are filtered and evaluated against preprogrammed target criteria. Dimensions: 320 × 350 mm (16 kg). Maximum depth is 150 m [490 ft]. Operational lifetime (depending upon frequency of alerts) is about 12 months.

SWITZERLAND

◆ Telemine

In 1983 the Swiss company Tek Sea announced that it was developing the Telemine remotely controlled torpedo to meet an Argentine navy requirement. The mine body is 55 cm × 5 m, with a maximum weight of 650 kg (170 kg of explosives). Powered by a 4.5-kW electric motor (up to 10 km at 20 kt), Telemine would be laid on the sea floor (at depths of up to 150 m), remaining dormant for up to 2 yr, and then being activated by acoustic signals from a distance as great as 4 km. Upon being activated, the mine releases its ballast and rises to near the surface. A sensor pod on Telemine's back carries an antenna, which penetrates the surface, for radio control by airplane, ship, or submarine. The sensor pod itself surfaces 500 m from the target, to provide the controller with a television picture of the target.

Tek Sea claimed that Telemine is almost undetectable by minehunting sonars because its acoustic density is so close to that of seawater.

TAIWAN

Taiwan uses a variety of domestic and foreign-produced mines. There are still large stocks of ex-U.S. antenna and contact mines, as well as magnetic (and probably pressure) bottom influence mines. There are also air-dropped cylindrical bottom mines (designated WSM-110) and Manta-like anti-invasion mines (WSM-210). WSM-110 resembles World War II influence mines, with slight tapering at 1 end for an appropriate trajectory, and 2 holes in the side for sensors. WSM-110 may be an adapted U.S. type.

USSR

Reports of total Soviet mine reserves vary. In 1987 the U.S. DoD claimed a total of 300,000 mines, including about 100,000 moored contact mines. These figures greatly exceed World War II usage (40,000 mines for the Soviets, 44,000 for the United States). Many of these mines have been exported to Soviet client states and allies, but it is often claimed that the Soviets do not export their pressure mines. Much of the data that follows dates from the early 1950s, in many cases from mines confiscated during the Korean War. Very little information has been released on more modern types, and information given here should be taken as representative rather than complete. For example, it seems likely that there are moored acoustic and magnetic mines, but no data or designations have been published.

Many of the designations given are no more than Western applications of standard Soviet mine categories, such as AMD; it is not always clear how the Soviets designate their equipment. Moreover, the historical record, even that part the Soviets have declassified, is not particularly clear. It is entirely possible that some of the descriptions below are really somewhat different references to the same weapon, or to versions of the same weapon. Some of the weapons listed may be Western projections or estimates rather than actual mines. In some cases (1970s and 1980s) in-service dates may be projections, some of which are now obsolete.

The old Imperial Navy was an enthusiastic supporter of mine warfare, but the expertise vanished with the revolution. A special technical bureau for mine development was established in 1921 and a mine testing center in 1924. However, stocks of earlier mines remained, and their designs were repeated in new production batches. M26 was the first entirely Soviet ship-laid mine. There was also a PLT series of submarine-launched mines.

It is reported that the Soviets have submarine-launched mines, 1 with a range of about 1 km.

The following inventory estimates were published unofficially about 1988; they are probably taken from a U.S. study dating from about a decade earlier. Even if they are official in origin, these figures do not pretend to be complete, as they do not include some earlier mines.

AMD-500	18,000
AMD-1000	18,000
AMD-IV	35,000
AMD-P-V	12,000
KRAB (Improved)	10,000
MAG	10,000
MKB-3 (Standard moored contact mine)	30,000
RVM	15,000
UEP	
KB-UEP	10,000
Sectionalized	10,000
Total of these types	168,000

◆ AGSB

Development of this antenna mine began in the early 1930s; it entered combat early in World War II. AGSB had two 35-m steel antennae (above and below) and the charge of an M-26, but AGSB could be laid in water 4 times as deep as M-26 (about 560 m). AGSB uses a 2-pulse operating circuit to overcome interference problems.

◆ AMG-1

This moored, air-dropped, contact mine appeared in 1939. It is laid like a bomb by aircraft (no parachute) from low altitudes (5–25 m) and can penetrate ice; it has an ogival nose and bomb type fins. Dimensions are 37 in (dia) × 141 in; charge is 572 lb of TNT in a 1080-lb case (with a 1200-lb anchor). Laying depths are 43–327 ft; case depth is 8–28 ft. Minimum spacing is 143 ft. Planting heights and speeds are 100–160 m at 260 kt, 160–600 m at 180 kt. AMG means aviation galvanic mine (*Aviatsionnaya Mina Gal'vanycheskiy*).

◆ AMD/KMD/KMK Series/MKD

Respectively, these devices are air/surface/submarine-laid ground mines, the number (-500 or -1000, but -1000 only in the case of submarine mines) indicating the weight in kg. For 500 and 1000 kg, respectively, maximum case depths (antiship) are reportedly 24.4 and 54.9 m [80 and 180 ft]; charge weights, 300 and 699 kg [660 and 1540 lb]; and minimum distance between mines, 69 and 137 m [226 and 449 ft]. If these mines are used against submarines, they may be laid at greater depths, up to 200 m [660 ft] for a -1000. Known influence mechanisms are (i) magnetic (horizontal or vertical component of target field), (ii) acoustic (HF or LF), (iii) pressure, and (iv) combination. There may also be others; what appears to have been a Libyan-laid KMD was recovered in the Red Sea in 1984, with a new type of influence mechanism. Approximate dimensions were 21 × 12 in. KMD reportedly incorporates a ship counter (up to 11 ships) and a delayed-arming mechanism (up to 10 days). The 1984 mine may have had a modular electronic firing mechanism to replace the earlier plug-in type.

Two KMK-1000 can be carried in lieu of a torpedo.

AMD, KMD, and KMK may be no more than generic designators.

The original AMD was the air-dropped version of the MKI magnetic induction ground mine. Dimensions were 21 × 11

in. Weight was 2167 lb total with 1725 lb of modified torpex. Maximum effective depth was 120 ft. MKD could be laid by aircraft, surface ships, and submarines; and it had an arming delay clock and a ship counter. MKD was the first modern Soviet ground mine.

An MKD torpedo-tube-laid (i.e., 21-in) mine recovered in the early 1950s had a 2-look magnetic fuze (interval 4–45 sec) to ensure that the object triggering it had some substantial size. However, the fuze tended to be more sensitive for the short period, so the mine was relatively easy to sweep. The mine also had a ship counter (0–11 ships) and a clock (0–10 days), as well as a hydrostatic safety. Its detection range was limited because of the limited length of its iron-dust (Sendust) core. The warhead was 1700 lb, equivalent to 2500 lb of TNT. Overall mine length was 114 in, of which 95.5 in was taken up by the charge.

AMD, which appeared in 1942, used a new magnetic induction mechanism based on that of the British A Mk 1, some of which were provided to the Soviets early that year. Compared to the British mine, AMD was considered more rugged and also more sensitive.

AMD-II-500 and -1000 (acoustic magnetic induction ground mines) were reported in 1950, carrying 300 and 700 kg of HE, respectively; the equivalent surface-laid versions (strapped to a dolly) are KMDs. Case depth is 50 m, and the acoustic element can be HF or LF or a combination. No AMD-III was reported, but AMD-IV-500 and -1000 (pressure/acoustic/magnetic) appeared in 1954. Reported characteristics are as follows: ship count, 1–21; arming delay, 12 hr to 10 days. The firing logic takes 3 looks. These mines have anti-countermine provisions. AMD-P-V (seismic/magnetic gradiometer) was reported in 1969 (the designation suggests a mine projected by U.S. intelligence rather than actually seen). This 1000-kg HE mine, which could be laid by ships, submarines, and aircraft, was credited with a ship count to 21, with a maximum delay of 30 days, and with anti-countermine provision. A remote on-off capability was possible. In 1970 AMD-S, a remotely controlled mine, was reported. Again, this last is more likely to have been a projection than a firm report.

The AMD designations above are U.S. or NATO, not Soviet.

The Libyan-laid Soviet bottom mine found in the Gulf of Suez in August 1984 (described as "995") was presumably a recent version of the KMD series. It was large enough to accommodate a 750-kg charge (the charge cavity was apparently not filled) and had acoustic, pressure, magnetic, and seismic sensors.

AMD means aircraft-laid bottom mine (*Aviatsionnaya Mina Donnaya*); KMD means ship-laid bottom mine (*Korabelnaya Mina Donnaya*); MKD means large ship-laid mine (*Mina Korabelnaya Bol'shaya*).

The original AMD-500 appeared in 1942. It is sometimes suggested that the KMDs, which first appeared in the early 1950s, were derived from captured German mines. These mines were exported from the early 1960s on.

♦ ATM

Autonomous Torpedo Mine (a U.S. designation) is a Captor-like weapon carrying a torpedo. It was first observed in 1984 when the Northern Fleet destroyer *Otlichnyy* was seen carrying 4 exercise examples.

♦ BPM-2

This swimmer-laid limpet mine (4 kg of HE) appeared in 1950.

♦ Cluster Bay/Cluster Gulf

Cluster Bay is a rising ASW mine, reportedly for use on the continental shelf. This mine is, therefore, comparable in concept to the Anglo-U.S. Crusader/Hammerhead. The rising body is a rocket, and it is fired on the basis of passive/active acoustic sensing. The rocket is presumably unguided, probably exploding when it reaches the expected target depth (as measured by the active sonar). The Soviet term for such a mine is *Reaktivno-Vsplyvayushchaya Mm*, and it would presumably have an RVM

designation. Reportedly, the charge is 500 lb, and typical case depth is 2000 ft.

Reportedly, RVM, a passive-action acoustic rising mine, appeared in 1969. There is also an A-RVM. Reported characteristics are as follows: case depth, 300 m [approx 1000 ft]; maximum bottom depth, 750 m; charge, 220 kg of HE (200 kg in A-RVM). Passive frequency is 46 kHz. The mine measures target range in a 158-kHz active mode and is propelled upward by a rocket motor to explode at a depth set according to measured target range.

G-RVM is a reported guided version to attack both submarines and aircraft carriers. Mooring depth is 60–1000 m, and case depth is 60–400 m [1300 ft]; possible attack range to the target is 600 m [660 yd]. The firing mechanism takes 2 looks at the range before raising the mine to the target. There is no ship count. Arming delay is up to 21 days, and sterilization can be set to up to 370 days. The active frequency may be adjustable.

The advent of this mine led to U.S. and other Western interest in very deep hunting/sweeping. The name is a NATO designation.

Cluster Gulf is reportedly a similar mine for use in deep water beyond the continental shelf. Recently, a Soviet torpedo mine broadly comparable to Captor has been reported.

♦ KB-1/M-31/MAV/KB-3

These mines are improved versions of M-08. KB-1 was a special 5-horned moored contact mine for use in icy water, the mine casing releasing a protective shield after laying. KB-1 could be laid down to a mooring depth of 160 m and carried a charge of 230 kg of TNT. KB-1 probably appeared in the early 1930s, and the aircraft-laid M-31 was very similar. Some of these mines were fitted with antenna firing mechanisms. The steel antennas caused problems; they could be a source of eddy currents in seawater, and those currents could explode the mine even if no target was present. The mine could also explode when the antennas corroded and broke. Currents caused by disturbances in the sea (e.g., the explosion of a nearby mine) could also explode the mine. KB-1's case depth is 10 m; maximum bottom depth is 272 m, and minimum spacing is 42 m. There was also an aircraft-laid MAV moored mine of about this vintage.

KB-3 (MA-39) was introduced in 1941. It carried horns, a 35-m antenna, and a 250-kg explosive charge. Its relation to KB-1/M-31 is not clear.

♦ KRAB

This moored influence mine is ship-laid, has a case depth of 18.3 m and a bottom depth of 272 m, and carries 230 kg of explosive. Minimum distance between mines is 41 m. KRAB is an acoustic device inserted into a standard MKB ellipsoidal mine case. Two reported passive frequencies are 22.5 kHz and 30–40 kHz. KRAB entered service in 1949, and it may have incorporated captured German influence mechanisms. An Improved KRAB of 1960 is a moored passive/active acoustic mine with an improved case and warhead; the passive frequency is reportedly about 200–250 kHz, the active (echo ranging) 30–40 kHz. The mine uses 2-look firing logic. It carries 250 kg of HE; the case depth is 150 m (maximum bottom depth is 600 m [1970 ft]). The ship count is 1–21, the arming delay is up to 21 days, and the sterilization time can be up to 370 days.

KRAB means large ship-laid inshore acoustic mine (*Korabelnaya Reydney Akusticheskaya Bol'shaya*).

♦ M-08

This contact mine, developed before World War I (1908), is currently manufactured in North Korea; this mine is currently being used by Iran in the Persian Gulf. M-08, a spherical moored mine, carries 5 chemical horns. Diameter is 34.5 in, and explosive charge is 253 lb of TNT. Total case weight is 500 lb, and the anchor weighs about 700 lb. Laying depth is 34–360 ft, and case-depth settings are 4–20 ft. Minimum distance between mines (to avoid countermining) is 120 ft.

M-08-4 mines, of Soviet design and North Korean manufacture, seized in the Persian Gulf in 1987 on board the Iranian ship *Iran Ajr*. (U.S. Navy)

This mine was developed from the 1898 version used in the Russo-Japanese War, modified for easier stowage and laying, with the mine casing, wire cable reel, and anchor stowed as an integral unit, and with the explosive charge increased in 2 stages (M-06 and M-08). M-08 could be laid at 18 kt.

M-08 uses chemical horns, which were considered somewhat dangerous to the crew laying them. The Czarist developers, therefore, tried inertia fuzes, which were battery-powered in the M-05 (1905) version. They were rejected as too sensitive and too short-lived. M-09 used mechanical firing pins and was the basis for the M-12 mine described below.

North Korean-made M-08 mines in the Persian Gulf have sometimes broken from their moorings. That breaking may mean that the North Koreans have used a heavier explosive charge, compensating by using a lighter and flimsier mooring chain.

◆ M-12 and M-26/KB

These moored mines have inertia-impact firing devices. M-12 is spherical (34.5-in diameter, 220 lb of TNT, 1320 lb total). M-26 adds a parallel midbody between 2 spherical caps (total length 52 in, 528 lb of TNT, 1210 lb total case weight plus 990 lb anchor). M-12 can be laid in 30–432 ft of water, with a case depth of 4–20 ft; M-26 in 30–456 ft of water, with the same case depths. M-12's minimum spacing is 100 ft, 180 ft for M-26 (because of the more powerful charge). M-26 has an anti-sweep device, perhaps the first in the world. Its mine case is carried horizontally on the carriage, lowering its center of gravity and simplifying its preparation for launching; it can even be carried on board fast patrol boats.

In contrast to M-08, M-12 adjusts depth by a hydrostatic pressure brake rather than by plummet. The mine separates from its anchor case after a preset delay (5 min–4 weeks).

KB was a modified M-26, a bomb-shaped mine for aircraft delivery, dropped without a parachute. Maximum mooring depth was 270 m, and the explosive charge was 230 kg of TNT. The horns were moved into position by springs after dropping. This mine was also described as Type Geiro, and possibly as AMG.

There is also an M-16 moored contact mine suitable for a maximum bottom depth of 366 m, carrying 115 kg of explosive, with a minimum spacing of 36 m.

◆ MIRAB

This ground magnetic induction mine was shaped in the form of a half-teardrop. Dimensions were 40.5 in (long) × 27.5 ×

27.5 in. Charge was 141 lb of TNT in a 616-lb case. Minimum spacing was 200 ft. The mine was originally intended to be air-dropped; but its case was not strong enough, and it was surface-laid.

MIRAB was developed as a river mine, for depths up to 7 m, against ships of 20 tons or more running at speeds of 2 kt or more. Effective range was 5 m or less. MIRAB originally used a vertical-field single-contact circuit, but that proved unstable, and the mine could be countermined (i.e., exploded by shock). The problem was solved by providing a directional condition. The final triggering circuit used 2 looks but had no ship counter.

Work on a river mine began in 1927, leading first to a weapon called RENIN and then to B.I.D.; MIRAB entered limited service in 1939. However, Soviet histories of their sea mines state that the first Soviet influence mines entered service only in 1945. The difference in dates may mean that the histories refer to sea, rather than to river, weapons.

MIRAB means aircraft induction river mine (*Mina Induktsionnaya Rechnaya Aviatsionnaya*).

◆ MKB/MKB-3/MAG

MKB was the standard Soviet surface-laid contact mine of the 1950s. Like M-08, MKB used 5 chemical horns. Diameter matched that of M-08 (34.5 in), but the case was larger (length 52 in) and thicker. The charge was 506 lb of TNT; case weight was 984 lb, and the anchor weighed 1415 lb. Laying depths were 34–894 ft, and case depths 8–30 ft. Minimum separation was 138 ft.

MKB-3 was similar, but with a shorter parallel midsection (length 47 in); charge weight (200 rather than 229 kg) and case weight were similar to those of the MKB. Minimum spacing was 35 m [115 ft] rather than 42 m [138 ft].

The basic design was repeated in the MAG and AMG-1. There were 2 types of charge container, and the horns might be distributed irregularly over the body of the mine.

MAG was a moored ASW antenna mine, otherwise similar to MKB (diameter 34.5 in, length 52 in, case weight 984 lb, anchor 1415 lb). Maximum laying depth was 1490 ft. Case-depth settings were 8–146 ft, and minimum spacing in a field was 115 ft. The mine could be used with or without horns. The lower antenna was 35 m long (diameter 11.6 mm); the upper, 24 m (6.3-mm diameter wire).

MKB means large ship-laid mine (*Mina Korabelnaya Bol'shaya*). MAG means galvanic antenna mine (*Mina Antenna Gal'vanicheskaya*).

MKB mines were used in Korea (with AMD/KMD mines) and also in Vietnam (they were laid late in 1966 and found in January 1967 in the Long Tau Channel to Saigon). The Egyptians used MKB in 1967 to block the Straits of Tiran, and then in the Suez Canal.

◆ MYaM (YaM)

This small ellipsoidal moored contact mine had 3 chemical horns. Dimensions were 21 in (diameter) × 22.8 in. Weights were 44 lb of TNT, with a 142-lb case and a 243-lb anchor. Laying depth was 9–167 ft; case depth, 2–9 ft. Minimum distance between mines was 66 ft. MYaM was probably an anti-small-craft mine (e.g., antisweeper). It was first reported in Korea in 1952, and both Iran and Iraq used MYaM in the Gulf War.

◆ MZh-26

This sweep obstructor (against paravane sweeps) was conceived in 1926. Suspended above the main mine body is a small buoy carrying an explosive cartridge intended to break the paravane wire. After 1 detonates, another (of 4 in all) rises to replace it. This type of mine is to be distinguished from a multiple mine, in which the main body carries 3 or 5 full mines, which are released in turn as the previous mine is swept away. That type of device appeared before World War I.

MZh means obstacle mine (*Mina Zagrashdenie*).

◆ Nuclear Mines

The Soviet Union reportedly has small stocks of nuclear ASW mines (yield 5–20 kT). The virtue of a nuclear mine is that it can destroy submarines at any depth, whereas a conventional moored or ground mine has only a very limited lethal volume around itself. The other simple solution to the depth problem, the string mine, is relatively cumbersome, the only known Western example being the Italian TAR. The nonnuclear solution to this problem is the rising mine (see Cluster Bay/Cluster Gulf above).

◆ PLT/PLT-Z

This cylindrical moored contact mine (inertia-impact fired) was to be laid by special submarine minelayers; no current Soviet submarines have tubes of sufficient diameter. Dimensions were 31.5 in (diameter) × 70 in. Total weight was 1850 lb, with 506 lb of TNT. Maximum laying depth was 450 ft; case depth, 13–30 ft. Minimum spacing was 262 ft.

PLT-Z was a moored contact mine laid from a submarine torpedo tube; it was fired by 4 galvanic horns. Dimensions were 21 in (diameter) × 94 in. Total weight was 2220 lb, with 220 lb of TNT. Maximum laying depth was 470 ft; case depths, 8–30 ft.

There is a submarine-laid moored sectional influence mine, carrying 500 lb of explosive; it can be moored in depths as great as 1600 ft.

PLT means submarine tube-laid mine (*Podvodnaya Lodnochnaya Trubnaya*). PLT-Z means submarine tube minelayer mine (*Podvodnaya Lodnochnaya Trubnaya-Zagraditel'*), i.e., a mine compatible with a standard submarine torpedo tube. It was developed during World War II. PL would simply indicate a submarine-laid mine. PLT-Z is generally (incorrectly) referred to as PLT-3.

◆ PLT-G/EP-G

These moored mines were introduced early in World War II, both of them for torpedo-tube laying by K-class cruiser submarines. Designed for upright laying from special tubes, EP-G was a deep-laying version of the PLT-G, introduced by the end of 1941. There is also reference to EP-SA, a wartime submarine-laid mine with a 200- or 300-kg explosive charge and 130 m [420 ft] of mooring chain. Shell diameter was 90 cm [35 in]. Reportedly, the torpedo-tube mine was not satisfactory, at least initially.

PLT-G means submarine tube-laid deep-water mine (*Podvodnaya Lodnochnaya Trubnaya-Glubokovodnaya*). EP-G means underwater electrocontact mine, deepwater (*Elektrokontaktynaya Podvodnaya-Glubokovodnaya*).

◆ Type R

This moored ship-laid contact mine has a case depth of 1.8 m [6 ft] and a bottom depth of 35 m [115 ft]. It carries 10 kg [22 lb] of explosive, and the minimum distance between mines is 15 m [49 ft]. R was a U.S. designation; the Soviet designation was not known.

◆ R-1

This small moored contact mine for shallow water is fired by 2 chemical horns. Dimensions are 19.5 in (diameter) × 6.5 in. Weights are 88 lb of TNT, 253 lb for the case, and 352 lb for the anchor. Laying depth is 3.5–115 ft; case depth is 1.5–5 ft. Minimum spacing is 66 ft. In very shallow water the mine does not separate from its anchor.

R-1 was a U.S. designation, indicating a mine whose Soviet designation was not known [R for Russian unknown].

◆ RMZ

This antihelicopter mine (to defeat helicopter sweepers) was reported in 1980. It is reportedly 2 m long, with a total weight of about 700 kg (charge of about 350 kg).

◆ UEP

Some Soviet mines exploit the underwater electric potential (UEP) of submarines as their fuzing mechanism. UEP is caused by the electrolytic action between the dissimilar metals in a ship, such as the steel of the hull and the bronze of the propeller. It has both DC and AC components, the latter the result of propeller rotation. Both are very inherently short-ranged, and they are very difficult to silence. The Soviets probably learned about UEP from captured German records; the Germans called it the electrode effect. The British experimented extensively with UEP just after World War II, including an attempt to use a towed UEP electrode to detect a torpedo running up a ship's wake.

Reportedly, the first Soviet UEP mine was a submarine-laid bottom weapon of 1944 with a range of 30 m [about 100 ft]. It carried a 226-kg [500-lb] charge and had a maximum case depth of 487 m [1597 ft]. In 1951 a ship-laid KB-UEP moored mine (a 40-m case depth, a 450-m maximum bottom depth) with top and bottom electrodes appeared, primarily for ASW. It carried a 240-kg [529-lb] charge and used 2-random-look firing logic. In 1960 the Soviets introduced an improved KB-UEP with longer electrodes, and it was suited to deeper laying (a 150-m case depth, a 600-m bottom depth). It carried a 250-kg charge and incorporated a ship count (1–21), an arming delay (up to 21 days), and a sterilization time (up to 370 days). The next reported version is the UEP moored mine of 1969, with a case depth of 100–200 m [328–660 ft] and a bottom depth of 600 m. It uses 2 charges (150 kg each), deploying into an 80-m [262-ft] array, with float, explosive, and firing mechanism separate. There is an inhibit option to prevent countermining. Unlike earlier UEP mines, which have ellipsoidal cases, this one has a cylindrical case. It is sometimes called a sectionalized mine because the 3 case sections separate when it is laid.

◆ YaRM

This small shallow-water contact (anti-invasion) mine carries a 3-kg charge.

UNITED KINGDOM

◆ Existing Mines

In connection with mine modernization programs, it is often suggested that Britain has manufactured no mines since World War II. However, there were several postwar programs, begun about 1953. Information is somewhat fragmentary.

In the past, there were 3 mine series: moored mines with Mk numbers, air-launched mines (A numbers), and special magnetic ground mines (M series). The principal mines, at the end of World War II, were the following:

A Mk 6 was an aircraft-laid ground mine (1800 lb; 960- or 1040-lb charge; magnetic, acoustic, combination, or pressure). Minimum depth was 40 ft. Dimensions were 18.45 in × 8 ft 6 in (9 ft 4 in including parachute). In 1949, 5707 were on hand.

A Mk 7, 7*, and 7** were 1100-lb ground mines (555- or 610-lb charges). Fuzing was magnetic or acoustic. Minimum case depth was 40 ft. Dimensions were 15.8 in × 7 ft 6 in (6 ft 11 in without parachute). In 1949, 4502 were on hand.

A Mk 9 was an 1850-lb ground mine carrying a 960- or 1060-lb charge. Fuzing was magnetic, acoustic, combination, or pressure. Minimum case depth was 40 ft. Dimensions were 18.5 in × 8 ft 6 in (9 ft 4 in with parachute). In 1949, 1427 were on hand and another 400 were on order. This mine was renumbered in 1955 and is probably still in service.

M Mk 1 was the standard buoyant magnetic mine, ship-laid in up to 1000 fathoms of water. It carried a 320- or 500-lb Amatol charge. A total of 8948 were on hand in 1949.

British Mk 5 bottom mine (in Australian service). (Klein)

British Mk 17 moored mines with Mk 18 bases (in Australian service). (Klein)

M Mk 2 was a 1760-lb ground mine (1020-lb Amatol charge), laid by submarine or coastal forces in 5–20 fathoms. 1310 are on hand.

M Mk 5 was running sea trials. It was a 1930-lb ground mine (1030-lb charge, with magnetic, acoustic, or combination fuzing) laid by submarines or coastal forces in 6.5–20 fathoms.

S Mk 6 is a postwar submarine (torpedo tube)-laid mine, a successor to *M Mk 5*.

Mk 15 was a buoyant contact mine carrying 320 or 500 lb of Amatol; it could be laid in water as deep as 1000 fathoms. A total of 1972 were on hand.

Mk 17 was a similar buoyant mine, which could be laid in 500 fathoms of water; 14,933 were on hand.

A Type S and A Mk 12, developed in 1953–56, were the new air-delivered ASW ground mines. Weights were 1000 and 2000 lb, respectively. Both mines used combination acoustic-magnetic-pressure mechanisms. At the time of development, the standard air-drop requirements were 450 kt/5000 ft (Royal Navy) and 35,000 ft in altitude (RAF). Minimum water depths (which determined the shock level the mine had to survive during laying) were 12 and 40 ft.

Mk 10 was a postwar aircraft-laid buoyant ASW mine, and its development began during World War II. *Mk 10* used a contact mechanism, and the length of its mooring cable had to be adjusted before flight. *Mk 10* was intended to be as simple and as inexpensive as possible, and it was the only means of mining deep water not accessible to surface ships and submarines. Total weight was 810 lb (100 lb of Minol charge). Maximum case depth was 600 ft.

Mk 28 and Mine "H" Type "T" As of 1956, 2 new surface-laid ASW mines were under development. *Mk 28* was an antenna mine, said to be more reliable (i.e., less subject to premature detonation) than others. Mine "H" Type "T" was a small moored mine, under trial in 1956. Presumably, it was intended for laying from small fast attack craft. There were also a variety

of experimental mines, including buoyant UEP (antenna) mines tried from about 1944 on.

These programs almost certainly died in the major post-1957 British defense reorganization, so that they probably represent the high point of British mine production prior to the 1980s. In 1959 the standard British naval mines were the following: ship-laid *A Mk 9/A Mk 12*, *M Mk 1*, *Mk 17*, and *Mk 28*; submarine-laid *M Mk 5* and *S Mk 6*; and air-laid *A Mk 9* and *A Mk 12*. There were also sweep obstructors.

Unfortunately, the reported postwar Mark numbers do not correspond to the 3 reported Mark numbers of existing British service mines. Presumably, existing mines were renumbered some time after 1956, the 3 series merging into 1. The 3 current types are:

Mk 5 Submarine- and ship-laid ground mine.

Mk 12 Air-laid ground mine.

Mk 17 Moored acoustic mine.

In 1982 the Royal Ordnance Factories proposed a modernized version of *Mk 5*, *Mk 5N*, with a microprocessor-controlled fuze (target designation module) that used a BAJ Vickers mine circuit emulator (MICE). This device could also be applied to existing stocks. *Mk 12* is now being modernized by British Aerospace. Finally, it was reported in 1986 that *Mk 17* mines have been fitted with a new acoustic sensor.

◆ Dragonfish

Dragonfish is the current production Marconi 85-kg [?] (80 kg of explosive) anti-invasion mine for use in shallow water (down to 30 m). Dragonfish uses 2 types of influence sensors. It has a 200-day operational lifetime. The technology used is similar to that in the Marconi Stonefish, which is designed to be laid in deeper water.

◆ Mine Modernization Program

Britain has not manufactured naval mines for some years, probably since the mid-1950s, but she has retained large stocks of these weapons. British Aerospace has received a contract to modernize existing ground mines. The existing units required lengthy prelaunch preparation and could make little or no target selection. British Aerospace designed a new microprocessor-based sensor and processing unit (SAP) that solves both problems, while retaining as much of the original mine as possible. A new safing-and-arming system can be added if desired, and high energy batteries make for a long shelf life. The mine can be programmed before it is launched.

As described in 1982, the SAP had only magnetic and acoustic sensors, the pressure sensor being built into the software (which covers frequencies down to 0 Hz). Acoustic signals would be analyzed in 3 bands, to cover sonar, engines, and propellers themselves, and thus to provide a high degree of target identification.

The modernization program was announced in 1982. It applied to about 1500 mines, some of them reportedly dating from the 1950s (and presumably of World War II type). In 1984 it was reported that the entire program might be abandoned because at least some mines were suffering from deterioration of their TNT or RDX filling. Some of it crystallized, causing at least 2 mines to explode prematurely. Such deterioration is quite common in civilian explosives such as dynamite and may limit the shelf life of existing mines, an important consideration for a country, such as the Soviet Union, with a very large stockpile, much of which must be elderly. Modern formulations are more stable, but reportedly the existing fillings cannot safely be steamed out once they have begun to deteriorate. In 1984 the reported solution was to X-ray each mine and to discard those whose fillings showed cracks or crystallization.

Thus far mine modernization has, apparently, been applied only to surviving World War II *Mk 12* mines.

Although the SAP was developed specifically for British mines, British Aerospace claims that SAP is adaptable to many

other types. Presumably, it is either identical to, or closely related to, the SAP of the Sea Urchin mine.

◆ Stonefish

This medium-depth modular magnetic/acoustic/pressure (either single- or multiple-influence) mine replaces earlier British types. Launched by airplane, ship, or submarine, Stonefish is suitable for water depths of 30–200 m. Dimensions are 53 cm (21 in) × 2.4 m (1.9 m exercise); weight is 990 kg (600-kg warhead). The training version weighs 440 kg. Shelf life is 20 yr, and life in the water is 700 days.

The original version is being replaced by a shorter, lighter Mk 36 (500 kg of PBX in place of the original 700 kg of Torpex) with simplified firing circuitry (over 30 components eliminated). PBX is an insensitive munition, supplied by the French SNPE company. Development is now almost complete; no customers have yet been announced.

As of 1989, 5 countries, including Australia, Britain, and Finland, had adopted Stonefish.

◆ Versatile Exercise Mine System (VEMS)

VEMS is a British Aerospace system designed to evaluate the performance of mine-countermeasures forces, both for exercises and for the development of new countermeasures. Each VEMS body can be programmed to simulate any known mine firing device, and VEMS can be recovered (and on-board test tapes removed) up to 6 months after laying. The manufacturer claims a 20-yr service life.

Dimensions are 533 mm × 2.71 m, and weight is 560 kg; the body includes a buoyant section that is released for recovery.

VEMS is currently in service with the Royal Navy and has been ordered for the U.S. Navy, the Thai navy, and the Royal Australian Navy.

UNITED STATES

◆ Destructors

Destructors (DST) were standard streamlined bombs converted into shallow-water mines during the Vietnam War. Mk 36, 40, and 41 were, respectively, conversions of bombs Mk 82, 83, and 84. The Destructor's firing mechanism was developed very rapidly, and at the end of the war it was stockpiled. However, these mechanisms cannot have met the usual standards for reliability or shelf life: hence the development of the Quickstrike Mines (Mks 62–65, see below). It is not clear how many, if any, Destructor mechanisms remain in U.S. war stocks.

Different Mods indicate different firing mechanisms: Mod 3 is magnetic; Mod 4 is magnetic/seismic; and Mods 5, 6, and 7 are magnetic/seismic with K Tab Capability. As disclosed to the North Vietnamese in 1973 (as part of Operation End Sweep),

DESTRUCTOR (DST) MARK 36

DESTRUCTOR (DST) MARK 40

DESTRUCTOR (DST) MARK 41

Destructors (converted Mk 80-series bombs).

the DST magnetic sensor is a thin-field magnetometer with selectable sensitivity. The seismic sensor is described officially as a detection battery. Presumably, it activates the magnetic sensor, so the mine cannot be exploded by a pure magnetic field.

Destructor Mk 36 was developed beginning in August 1966, and the first deployment was in June 1967. Mods 0 and 1 require retarded delivery; Mods 2 and 3 can be delivered unretarded against land targets. Mod 0 has fixed arming delay and fixed self-destruct. Mod 1 has selectable arming delay and introduces a probability actuator. Mod 2 has selectable self-destruct as well as selectable arming delay and probability actuator, and it is suited to unretarded delivery. Mod 3 adds a sensitivity option for increased countermeasures resistance. The arming delay allows the weapon to become physically stable in the presence of water currents and wave action and hence allows its firing mechanism to become magnetically stable.

Destructor Mk 40 was developed in 1968 for greater damage effectiveness against land targets. Mods 2 and 3 may be dropped unretarded against land targets using conical fins like those of Mk 36 Mods 2 and 3.

The bomb modification kit is Destructor Modification Kit Mk 75. The original program called for 22,125 kits in FY67 and 20,250 for FY68, but in July 1967 the program was increased to 111,865 kits and in November 1967 to 148,998; by 1970, over 300,000 had been made.

Destructors Mk 36 and 40 development ended in FY70, effort switching to Mk 41 and 42 (Quickstrike) following recommendations of the NOL Minetech study, Mine Advisory Committee Nimrod study, and an Op-95 ASW R&D assessment.

There is also a Destructor M117D Mk 59-0 (1985), which uses the standard air force 750-lb bomb, with Arming Device Mk 32-1, battery, and firing mechanism Mk 42-4; the total weight is 857 lb. It is intended for minelaying by B-52s.

◆ Mk 6

This antenna mine was developed during World War I for the North Sea antisubmarine barrage and subsequently became the main U.S. surface-laid contact weapon. Mk 6 was used during World War II and was probably distributed to U.S. allies post-war. It was a 34-in sphere containing 300 lb of TNT (1400 lb total, including sinker) and could be moored in up to 3000 ft of water. Mod 3 had a 100-ft lower antenna, and Mod 4 a 50-ft lower antenna. Versions differ in type of sinker. All of these mines have Hertz horns in addition to their antennas (Mods 14 and 15, approved for service use in 1955 and 1964, respectively,

Mk 6 practice mine being launched. (U.S. Navy)

were limited to contact operation). All versions of Mk 6 were withdrawn from U.S. service in 1970.

◆ Mk 13

Mk 13 was an aircraft-laid magnetic mine, delivered without a parachute. This mine could also be used as a bomb. Total weight was 1048 lb, including 640 lb of TNT, or 1118 lb, including 710 lb of Torpex explosive. Mods 1 and 2 were redesignated Mk 26 Mods 0 and 1 (which was not produced); Mod 3 (with a parachute) was not issued; Mod 4 was designed for shallow water. Mod 5 (990 lb, including 640 lb of TNT, or 1060 lb, including 710 lb of TNT) had an acoustic exploder. Mod 6 (1020 lb, including 640 lb of TNT, or 1090 lb, including 710 lb of TPX) had an acoustic exploder and was fitted with a parachute.

Mk 36 might be considered a development of Mk 13, via Mk 26. Prior to development of the Mk 52 series, Mks 13/36 were the primary U.S. lightweight aircraft-laid bottom mines, and Mk 25 was the primary heavy equivalent. All were exported to U.S. allies postwar.

◆ Mk 16

Mk 16 is a contact (Hertz horn) mine, ovoid in shape (Mk 6 is spherical). Mk 16 carries 600 lb of HBX-1, total weight being 2040 lb. Exported postwar, Mk 16 was originally conceived as a successor to the Mk 6 antenna mine. Mod 0 was a moored induction mine. Mod 1 was a contact mine similar in operation to Mk 6. Mod 2 was a moored acoustic mine.

◆ Mk 18

Mk 18 is a surface-laid bottom magnetic mine, cylindrical in shape (with the cylinder axis vertical), with a prominent vertical post protruding from it. The mine is provided with wheels beneath the cylinder so that it can be run down a track on board the laying ship. Total weight is 2140 lb, including 1440 lb of HBX-1. Dimensions: diameter 42 in × 72 in maximum height. Mk 18 was exported to U.S. allies in the 1950s, to be used to mine shallow strategic straits. There is no other U.S. ship-laid bottom magnetic mine of the same vintage.

◆ Mk 25

The standard U.S. World War II aircraft-laid bottom mine was exported postwar, and it was used during the Vietnam War. It is no longer in U.S. service (Mod 0 withdrawn in 1970, Mod 2 withdrawn in 1974). Weight was 2000 lb total (1234 lb of TPX or 1200 lb of HBX). Dimensions: 22.4 × 87.2–93 in (depending on flight gear), i.e., roughly the size of the contemporary aerial torpedo Mk 13. In 1980 new flight gear was being issued to permit this mine to be carried at high speeds. Mod 1 was acoustic, Mod 2 pressure/magnetic.

◆ Mk 36

Mk 36 was an air-laid bottom mine with a flat slanted nose for optimum underwater trajectory. Mods 0 and 1 were magnetic (induction) mines; Mod 2 was LF acoustic, and Mod 3 was pressure/magnetic. Magnetic version weights: 940 lb (including 570 lb TNT) or 1008 lb (including 638 lb TPX). Mod 2: 1024 lb (including 570 lb TNT) or 1082 lb (including 638 lb TPX). This mine was exported postwar to allied navies. This mine is no longer in U.S. service (Mods 1 and 3 were withdrawn in 1974, and Mod 2 in 1970).

◆ Mk 49

Mk 49 is a submarine-laid ground mine designed postwar to match the operational versatility of contemporary aircraft-laid mines (particularly Mk 25) at a lower cost than the earlier Mk 27. It was first tested in 1951. Although no longer in U.S. service, Mk 49 was exported to Allied navies, some of which probably still use it. Versions: Mod 0 (magnetic induction with arming delay and ship counter), Mod 1 (LF acoustic with ship counter, arming delay, and sensitivity set automatically by sensed water depth), and Mod 2 (combination magnetic and pressure). Dimensions: 20.8 × 94.9 in (1880 lb, including 1100

lb of HBX; Mod 2 is 1840 lb, including 1100 lb of HBX). These mines were later modified, lengthened to 120 in (Mod 0, 2000 lb; Mod 1, 1890 lb, including 1180 lb of HBX-3; Mod 2, 1960 lb, including 1180 lb of HBX). Mods 0 and 1 can be planted in up to 200 ft (they can function in 16 ft). Recommended depth for Mod 2 is 30–100 ft (it can tolerate 20–150 ft). Recommended spacing: 200 ft on hard bottom, 150 on mud (Mods 0 and 1), 300 ft for Mod 2.

◆ Mk 50

This postwar (1952), lightweight, air-laid ground mine was for canals, rivers, and other shallow waterways. It used an acoustic firing mechanism that responded to hull vibrations of small vessels, a choice that contemporary sweep gear could not mimic. The Destructors were, in effect, the successor. Mk 50 was designed to fit a 500-lb bomb rack. Dimensions: 14.1 × 56.6 in (580 lb, including 238 lb of HE). When carried externally, Mk 50 was faired to a length of 89 $\frac{3}{8}$ in (603 lb). It could be launched at any altitude over 200 ft and at any air speed not over 300 kt. It armed positively in water 12 ft deep and was most efficient in 12–60-ft depths. Arming delay: 0 or 3–100 days.

Mine Mk 50. (U.S. Navy)

◆ Mk 51

This controlled mine for harbor defense is typically laid in groups of 13. Mk 51 is a vertical cylinder (62 × 37 in), carrying 3275 lb of TNT (total weight is 6200 lb). Mk 51 resembles Mk 18, but Mk 51 is substantially larger. This weapon was probably exported after World War II. Mk 51 Mod 0 was designed to counter conventional submarines, and it was modified postwar (to Mod 1) to counter midgets down to a 30-ton displacement. Mod 1 uses Acoustic System Mk 6, a line of hydrophones. The mine itself has a magnetic induction sensor. The operator ashore, who can monitor 10 hydrophone channels (13 mines group), has access to both the acoustic and magnetic sensor outputs. The operator times mine firing based in part on a judgment of the size of target. Target size is indicated in part by the number of mines responding to the target.

◆ Mk 52

The first of a postwar series of modular antisubmarine mines Mk 52 was the 1000-lb-class air-laid weapon. The World War II air-laid mines (such as Mks 25 and 36) used component plugged into the side of the mine; the Mk 50 series used an instrument rack inserted at 1 end of the mine to carry the firing mechanism, clock mechanism, sterilizer, and associated batteries. The tail cover had 3 openings for target-detecting device in contact with the sea, and there was a well for the hydrostatic arming device. When it appeared, Mk 52 offered more flexibility

Mine Mk 51 (practice version). The vertical tube is the magnetic-induction sensor. This and Mk 18 are the only U.S. mines in the form of upright cylinders. (U.S. Navy)

in fewer different components in 1 package than ever before. The mine could be dropped either in cylindrical form with box fins (for internal carriage) or in streamlined form with a round nose and a pointed tail (with pop-out fins). It used new influence field detectors and 3 types of associated firing mechanisms: pressure, acoustic, magnetic. Versions: Mod 0 (pressure), Mod 1 (acoustic, 1130 lb), Mod 2 (magnetic, 1170 lb), Mod 3 (pressure-magnetic, 1190 lb), Mod 4 (pressure-acoustic), Mod 5 (magnetic-acoustic, 1200 lb), and Mod 6 (pressure-acoustic-magnetic, 1235 lb). Mod 7 (magnetic) and Mod 8 (pressure-magnetic) were abortive. In each case, dimensions were 18.8 × 70.2 in, and the charge was 625 lb of HBX-1. Mk 52 could deal with a submarine moving at only 3 kt and could be adjusted in sensitivity. It had a 30-count ship counter and a 1-hr to 90-day delay arming mechanism. It could be used in place of a standard unstreamlined 1000-lb AN-series GP bomb.

As disclosed to the North Vietnamese in 1973 (as part of Operation End Sweep), Mk 52 Mod 2 had a 2-look, reverse polarity, magnetic-induction fuze, with selectable magnetic sensitivities, interlock, dead periods, intership dead periods, ship counts, and preset self-sterilization/self-destruction times.

Mk 52 was part of the U.S. Long-Range Mine Program begun in 1948 and was released for production in January 1954 (operational evaluation began in October 1956). It became operational in 1961. Mod 1 was withdrawn soon after, to be superseded by the other versions, of which Mod 4 was withdrawn from service in 1978. Mk 52 was produced in West Ger-

Mine Mk 52. (U.S. Navy)

many and may have been exported to other allied navies. In FY60 each of 2500 Mk 52 mines cost about \$4900.

◆ Mk 53

Mk 53 is a 500-lb air-dropped sweep-obstructor (to protect mine fields against sweepers), the first such to enter service. Reportedly, the entire U.S. stock was transferred to Turkey in 1978. Mk 53 fires when a sweep wire contacts the firing ring in the base of the mine case. Dimensions: 14.125 × 52.367 in (365 lb) in unstreamlined form (Mk 53 resembles an unstreamlined bomb with a box tail). For external carriage, it is faired at the ends, with a blunt nose and a pointed tail (which opens into stabilizing fins). Total length is 77.559 in (395 lb). Mk 53 can be planted in water as shallow as 36 ft, with a case depth of 24–300 ft.

Mine Mk 53. (U.S. Navy)

◆ Mk 55

Mk 55 is the 2000-lb-class air-dropped bottom mine corresponding to the Mk 52 series; Mods 1–6 corresponded to Mk 52 Mods 1–6. Mod 0 was pressure-fired. Mod 7 used an improved dual-channel magnetic-firing mechanism. Components were interchangeable with those of Mk 52. Dimensions: 23.38 × 89.875 in (142.625 in when faired for high-speed carriage). Weights (Mods 1–6): 2039, 2110, 2120, 2119, 2128, 2118 lb. These mines could be laid by surface ships using portable rails. They were exported to some allied navies.

Mk 55 was released for production in November 1955 and became operational in 1961. In FY60 each of 1400 Mk 55 mines procured cost about \$5500. Of the versions, Mod 0 was withdrawn from U.S. service in 1963, and Mods 1 and 4 in 1978. The others presumably remain in service; the successor weapon is Quickstrike (Mk 65).

Mine Mk 55. (U.S. Navy)

◆ Mk 56/57

Mk 56 is a 2000-lb aircraft-laid moored mine (22.4 in × 114.3 in), with a 360-lb charge (HBX-3). Mk 57 is a similar submarine-laid magnetic moored mine (2059 lb, 340 lb of HBX-3,

Mine Mk 56. (U.S. Navy)

21 in $\times$ 121.1 in), for water up to 200 fathoms deep. Mk 56 uses a total-field magnetic exploder and has a stainless-steel nonmagnetic case.

Mk 56 could be set to moor at an adjustable depth (30–480 ft). Compared to earlier air-laid moored mines, it has an increased range of planting depths and a variable mine-case release timer. It enjoys greater target selectivity through the use of a new total-field magnetic-influence mechanism that can be adjusted to respond equally well to slow or fast targets. Minimum sensitivity is about 20% that of the earlier Mk 10. Like the air-laid Mk 50 series, Mk 56 is easier to assemble because it employs modular components. It has a ship counter (1–30 counts); Mk 10 has none, and Mk 36 has 1–10. Variable planting depth is 150–600 ft, compared to 100–400 ft for Mk 36. Assembly time is 2 hr, compared to 6 hr for Mk 10 and 8 hr for Mk 36. Mk 52 arms in 1 hr, compared to 65–180 min for Mk 10. When Mk 52 appeared in 1957, it was described officially as a realistic threat to submarines, whereas the earlier Mk 36 represented only a limited threat.

Mk 56 was released for production in 1960 and became operational in 1966; Mk 57, the submarine-laid version of Mk 56, with a fiberglass case, was released for production at the same time and became operational in 1964. In each case, the delay was caused by a lack of funding for production at the time.

Mine Mk 56 as carried on the centerline of an A-4 Skyhawk, 1965. The control unit in the tail of the mine is marked Mk 66. (U.S. Navy)

Mine Mk 57.

◆ Mk 60 (Captor)

This deep-water ASW mine was conceived about 1960 and developed at NSWC at White Oak. A tentative specific OR was issued in November 1962, the name Captor being selected for a specific OR issued in May 1964. At that time it was hoped that Captor would reduce mine barrier costs by a factor of 100 (and barrier numbers by a factor of 400). The first production contract (for Techeval/Opeval) was awarded to Goodyear Aerospace (now a division of Loral) in 1972. Technical evaluation began in February 1974 and operational evaluation in June. Initial operational capability was achieved in September 1979 and approval for service use granted in February 1980. This very protracted development testifies to the complexity of the system. In fact, reliability problems prompted a suspension of production in 1980, procurement being resumed in FY82.

Captor (the encapsulated torpedo) is a Mk 46 Mod 4 torpedo encapsulated in a mooring/sensing body that passively detects and tracks submarines passing overhead. When a supposed track is sufficiently attractive, Captor begins active tracking and then launches the torpedo upward. This mode of operation will work in almost any depth because it utilizes reliable acoustic path (RAP) sound propagation. Determination of the target's initial bearing is by passive acoustic correlation and low-power digital processing, using techniques originally developed for the PUFFS (BQG-2/4) submarine sonar project. The mine body can be air-, surface-, or submarine- (torpedo-tube) launched, and it can moor in water at least 1000 ft deep. Lifetime is several weeks or months. Dimensions (weights) for the air/surface-launched versions are 21 $\times$ 145 in (2370 lb); for the submarine-launched version, 21 $\times$ 132 in (2056 lb).

During techeval in 1974–February 1975, its detection and classification system suffered from excessive false alarms, and the system was unreliable. However, Captor had shown sufficient potential to warrant further work, and follow-on test and evaluation of initial production units was suggested. Provisional approval for service use (ASU) was granted in January 1976; at this point the production rate was limited to 10 per month. Follow-on test and evaluation, using 10 Captors, began in January 1978. Full-scale production (15/month) was approved in March 1979. At that time the ultimate objective was 5785 Captor mines.

At that time, too, the Captor project included an attempt to control it remotely (RECO) by acoustic signal. This work was still proceeding a decade later; the FY88 program included initial studies of ambient and self noise. RECO now applies to Captor, Quickstrike, and advanced mines of unspecified type. The project is being managed by NSWC White Oak; the contractors are APL and Penn State University.

Captor is now being modified to accept a Mk 46 Mod 5 (NEARTIP) torpedo as its warhead. The hardware design for this Mod 1 version was completed under the FY88 program.

Mine Mk 66 is the practice version of Captor.

Procurement began in FY78, the FY78–80 budgets including 1810 Mk 60s. None were bought in FY81, but FY82 included a

Mine Mk 60 (Captor).

Mk 60 mine and its Mk 46 torpedo payload. (Goodyear)

request for another 400 Captors. Subsequent procurement: FY83, 300; FY84, 300; FY85, 300; FY86, 150 (unrequested). As of 1985, plans called for 475 in FY85, 600 in FY86, 493 in FY87, and none in FY88. Unit cost in FY86, the last year of procurement, was about \$377,000. In comparison, the unit cost of Captor was \$113,000 in FY78.

◆ Mk 62/64 (Quickstrike)

These conversions of standard streamlined bombs (Mks 82, 83, 84, respectively: 500, 1000, 2000 lb) supersede Destroyers EX-52 through -54. The Destroyers were magnetic-fuzed. These weapons can be dropped either on land (where they can be exploded by the magnetic signatures of vehicles) or in shallow water. Assembled very quickly using stored fuzes, Mk 62/64 are called Quickstrikes. All have standard thick-walled bomb casings, and their tails are adaptable to parachutes.

These weapons use 2 alternative target-detection devices (TDDs): Mk 57 (magnetic-seismic) and Mk 58 (magnetic-seismic-pressure). Presumably, seismic is, in effect, an acoustic sensor using sound as transmitted through the sea floor rather than directly through the water. These units are to be replaced by new Mk 70 and Mk 71 TDDs.

The great advantage of this program is that the United States need not stockpile large numbers of bottom mines. Instead, it can stockpile an equivalent number of specialized exploders. The logic is much the same as for the standard U.S. guided bombs, which are assembled by adding special modules to standard Mk 80-series streamlined bombs.

Mk 62 was approved for service use in 1980. As of about 1986, plans called for procurement of 39,804 Mk 70/71 TDDs, plus 3000 Mk 57 and 2500 Mk 58. Actual TDD procurement: Mk 57: 1575 in FY83 and 1753 in FY84. Mk 58: 75 in FY84, 165 in FY85, 400 in FY87, 300 each in FY88 and FY89.

Quickstrike was conceived as a new series of bottom influence mines, to enter service in 1976, to attack submarines, surface ships, and fast patrol craft. Initially the program called for 2 configurations, 500 and 2000 lb. The CNO Tactical Air Armament Study directed that the 500-lb Advanced GP Bomb (AGPB) be used for the smaller Quickstrike; the larger Quick-

Quickstrike Mines (Mks 64 above and 65 below).

strike was designed to be adaptable as a demolition bomb in the AGPB family. Both were to be air-deliverable, and the 2000-lb weapon was intended for air and submarine delivery. Quickstrike was intended to replace the earlier Mks 25, 36, 52, and 55 bottom mines and Destroyers Mk 36 and Mk 40.

The development of the Quickstrike series and its associated TDDs is justified on 2 grounds. First, the existing devices, as well as the Mk 52 series ground mines, were all compromised in Vietnam. Second, they are all becoming difficult to maintain and are no longer being manufactured. For example, their batteries must be stored under refrigeration. Quickstrike's design emphasizes ease of maintenance and also ease of mine preparation for use. All the Quickstrikes are air-delivered. The corresponding submarine-delivered bottom mine is Mk 67; there is no corresponding ship-delivered bottom mine.

◆ Mk 65

A 2390-lb modular mine (29 in across fins × 128 in), Mk 65 is the only Quickstrike not converted from a standard bomb. Unlike Mk 64, Mk 65 has a special thin-walled casing and a special

Mk 65 Quickstrike being prepared for flight. (U.S. Naval Institute)

arming device. Aerojet received the Mk 65 contract on 15 April 1982. Mod 0 uses a Mk 57 TDD; Mod 1 uses a Mk 58 TDD.

In 1985 Aerojet, the U.S. manufacturer, and Misar of Italy agreed to allow Misar to market Mk 65 in Europe. A new family of microprocessors developed by Misar will replace the U.S. Mk 58 multisensor TDD (trigger unit).

Mk 65 was approved for service use in 1983. Procurement: 307 in FY82, 579 in FY83, 600 in FY84, 524 in FY85, 1445 in FY86, 500 in FY88, and 524 in FY89, for a total of 4479 against a planned total of 4500. As of 1985, plans called for 559 in FY85, 743 in FY86, 743 in FY87, and 777 in FY88; the new schedule brought out the planned production run early. Actual procurement was 1445 in FY86; as of late 1986, plans called for 500 in FY88 and 524 in FY89 (none were bought in FY87).

◆ Mk 67 (SLMM)

The submarine-launched mobile mine was converted from a Mk-37 torpedo and was designed to be fired into a mine field from a distance. Engineering development began in FY77, and advanced development was completed in FY78. Mk 67 Mod 2 was approved for service use in FY83. A submarine successfully launched a Mk 67 mine (using fire-control panel Mk 281) during FY87; this completed development and introduced the mine into the fleet. The major contractor is the Dewey Corp. of Oakland, New Jersey, which makes the explosive section. NUWES (Naval Underwater Weapon Experimental Station) Keyport refurbishes the Mk 37 afterbody and builds up the full Mk 67. The goal, as of early 1988, was to attain the full inventory objective in FY91, using refurbishment money programmed in FY88 and FY89. In 1982, when the mine was approved for service use, the objective was 2421 mines (up from 1729). Procurement: 101 in FY82, 266 in FY83, 242 in FY84, 280 in FY85, for a total of 889. Plans for further procurement were not carried through. As of 1985, they were: 290 in FY86, 284 in FY87, and 266 in FY88, for a total of 840. However, the 1988 statement suggests that some mines have been manufactured using torpedo-refurbishment funds.

This weapon uses TDDs Mk 70 and Mk 71.

Mine Mk 67 (Submarine-Launched Mobile Mine).

◆ EX-68/IWDM/Substrike

PRAM was a proposed rocket-propelled 2000-lb weapon with a 500-lb warhead, which could be driven about 1 mile by its rocket. It was canceled in 1978 after having been conceived in the late 1960s. Engineering development would have begun in FY79, but reportedly its target sensor proved unworkable. Officially, it was dropped because of the Office of Management and Budget's regulation A-109, which required that the service no longer issue specifications describing projected weapons but instead focus on required performance. The regulation would allow for more alternative concepts. The navy, therefore, issued an RFP for what was called the intermediate-water-depth mine (IWDM). The competitors were Aerojet, Bendix, General Electric, Goodyear, Gould, and McDonnell Douglas. IWDM's dimensions were limited to 21 × 144 in (so that 2 could fit 1 torpedo skid). IWDM was to be laid by submarines, ships, and

aircraft. It would detect, classify, and localize surface ships and surfaced or submerged submarines. Demonstration-validation contracts were awarded to General Electric and McDonnell Douglas on 30 September 1980. Although IWDM was canceled it remains interesting as an indication of the nature of the projects that succeeded it. The demonstration/validation models were scheduled for delivery in June 1984, with operational evaluation in FY87. It was expected that 108 RDT&E models would be purchased, and that ultimately 6240 would be bought for \$838.5 million (about \$134,000 each). IWDM, in turn, was replaced by the new-generation mine (NGM), and then by the Anglo-American advanced sea mine (ASM) or continental-shelf mine (CSM). ASM was canceled in 1989 when Britain withdrew. There were 2 competing versions: Crusader was a rocket projectile, and Hammerhead was a torpedo. The issue was cost and capability: some have argued that any mine traveling more than about 500 m requires some degree of mid-course guidance. As of late 1989, the navy was drafting a new OR; the mine will be called Substrike.

◆ Mk 69

◆ Mk 70

Exercise and training mine for Mine Mk 52.

◆ Mk 71

Training device to duplicate the trajectory of Destructor Mk 40

◆ Mk 72

Training device for Mine Mk 56.

◆ Mk 73

Training device for Mine Mk 55.

◆ Mk 74

U.S. designation for British VEMS (versatile exercise mine system).

◆ Universal Laying Mine

Universal laying mine is a mine development project. Procurement was 3500 in FY86, at a total cost of \$3.7 million. None were bought in FY87, but late in 1986 the navy hoped for 2400 in FY88 and 3600 in FY89. Engineering evaluation was completed during FY86, and approval for full production was expected late in FY87. Details have not been published, but presumably the universal laying mine is a new moored mine to replace Mk 56/57. The new mine is included in the same program element as the Quickstrike series of new bottom mines. No Mark number has been announced.

This mine may be associated with a new parachute flight gear Mk 16 for 500-lb mines.

◆ MOWAM

EDO's private-venture mobile mine project is designed for use principally against amphibious vehicles in shallow water. MOWAM would be deployed from helicopters or small patrol craft. MOWAM would appear to be a bottom-laid rising mine triggered acoustically, that would use a rocket motor and a magnetic proximity fuze. These data were published in 1986.

YUGOSLAVIA

In the mid-1960s Yugoslavia acquired Soviet KMD-500 and KMD-1000 influence mines (the M70 described below is presumably a locally made version of a Soviet mine). In 1975 the Yugoslav government announced that it had 2 new acoustic mines in production, *Koral* (coral) and *Biser* (pearl). However, neither appears in a catalog of Yugoslav naval weapons available for export issued in 1989. A drawing in the catalog does show a river minelayer carrying Soviet-type river mines. This is not the drifting river mine described below.

Acoustic-Induction Mine M70

This surface- and submarine-launched acoustic-magnetic bottom mine is to be used against warships of up to 5000 tons and merchant ships of up to 20,000 tons, at depths as great as 50 m against surface ships (150 m against submarines). Its electronics employs printed circuits. Dimensions: 534.4 mm × 2823 mm (21 × 111 in); weight 1000 kg (700 kg of explosive).

PLRM-1A

This drifting river mine floats upright, suspended from a float carrying a circular wire bumper. Total draft is 500 mm. Dimensions: 260 × 370 mm (mine proper); weight 14 kg (10 kg explosive). Fuzing is mechanical (clockwork).

SAG-2b

This locally produced contact mine, with a total weight of 600 kg (115 kg of explosive), can be laid in 110 m of water. This mine must date to the 1950s or before.

MINE COUNTERMEASURES/MINEHUNTING SONARS

Very precise navigational systems are essential to mine countermeasures because the sweeper must be able to identify the position of the cleared channel. Examples include the Racal Hyperfix (accuracy 5 m at 250 km) and the U.S. Precision Navigation System. Raydist, which was used to control the U.S. sweeping of Hanoi/Haiphong in 1973, was an extemporized civilian system using antennas on shore. Minesweeper navigation also requires high-definition surface-search radars, many of which are listed in the Anti-aircraft Warfare section.

AUSTRALIA

The Royal Australian Navy announced a COOP program in November 1989. Two of the craft will have a seabed-survey capability, using a commercial towed side-scan sonar, the Klein 595.

CANADA

◆ Manta

See the British FIMS, below.

◆ MCDV SOR

Several companies are currently competing to provide the minehunting and other systems of the new Canadian maritime coastal-defence vessels (MCDVs), which are part of the naval reserve mine-countermeasures project (NRMP). The MCDV is to conduct mechanical sweeping, route survey, hunting, and mine disposal. It is to employ a single integrated combat system, preferably using multifunction equipment for the different roles. The SOR (specific operational requirement) asks that the combat system's display and processing equipment be compatible with other ship's systems, that it be closely connected with the ship's command/control and integrated navigational systems, that it be located in the ship's operations room (CIC), and that it incorporate new technology.

The likely combat system alternatives are a CDC system based on SHINPADS but using the new MAGICS2 display (which is faster than that of SHINPADS and has more memory), FIMS (Ferranti's MC500), and NAUTIS-M (with an ROV-carried mirror sonar). There may also be a Canadian Litton proposal. In each case, it is expected that the standard multifunction console will provide sensor (including ROV) video as well as synthetic graphics.

The SOR calls for navigation to be accurate within 10 m.

The route survey is to be conducted with a towed sonar fish, the data from which are to be consolidated into a data base under heads such as minelike and nonminelike objects. It must cover at least 4 km²/hr, and objects 0.5 m in diameter must be detected at a depth of 200 m (300 m desirable) at a range of 200 m; they must be sorted into minelike and nonminelike categories at a range of 100 m, and their positions recorded to within an accuracy of 10 m. The survey's endurance must be at least

144 hr, and the sonar picture may be transmitted to a shore station during the survey.

The minehunting system must operate at a distance from the MCDV (which will be steel-hulled, hence vulnerable to influence mines). The SOR favors an ROV capable of largely autonomous operation (e.g., underwater-obstacle avoidance), following a programmed route while detecting objects with low magnetic and acoustic signatures. It will pass data continuously back to the parent ship, using a cable or a radio link (see the Rockwell Dolphin system described in the U.S. section), and must operate at least 600 m (1000 m desirable) ahead of the parent ship. Desired area coverage, with a high detection probability, is 2 km²/hr against moored and bottom mines ($\frac{1}{3}$ km²/hr vs. buried mines). Endurance is to be 4 hr (12 desired). Required positioning accuracy of the ROV relative to the MCDV is probably 1 or 2 m.

The ROV must also be capable of mine disposal, perhaps involving actually moving the mine out of a shipping lane.

The planned mechanical sweep is to operate down to 200 m (300 m ultimately desired), clearing a 350-m path at 10 kt on 1 side. Sweep depth-keeping and recording of deployed cable are to be automatic, and all sweep gear must be stowable between decks.

The SOR exceeds the capabilities of current systems.

◆ Model 971

Mesotech's color imaging sonar for remotely controlled underwater vehicles uses a rotary or side-scan transducer at 120–675 kHz in fan or conical beams.

Mesotech is part of the Simrad (Norwegian) group.

◆ Model 972

Mesotech's 972 side-scan sonar in a neutrally buoyant towfish, operating at 120 and 330 kHz (beam patterns 2.4 × 60 and 0.9 × 60 deg, respectively). Pulse length is 5.3 msec, corresponding to 5 m. Display ranges are 5, 10, 15, 25, 50, 75, 100, 150, 200, 300, 400, and 500 m. The video display is 1280 × 1024 pixels (128 levels of color). The towfish can also accommodate a sub-bottom profiler. Maximum working depth is 1000 m [3280 ft]; altitude sounder range is 300 m [980 ft]. Altitude sounder resolution is 0.07 m [0.23 ft]. The fish weighs 14.8 kg (165 × 1316 mm). Model 972 has a high-resolution color display and records its data on VHS tape for replay.

◆ Trail Blazer

See the British entry, below.

CHINA (PRC)

◆ Type 312

This remotely controlled magnetic and acoustic minesweeper is similar in concept to the German Troika system. Type 312 can also operate manned. Displacement is 46.95 tons fully loaded (dimensions 20.94 × 4.20 × 1.30 m), and propulsion is by a 300-BHP diesel. Radio control is effective to about 3 nm, and the craft is electrically driven at 1–5 kt. All equipment is shock-mounted, and the hull form is intended to reduce the shock effect of the mines the craft detonates. These craft have a laser precision navigation system. They are limited to coastal waters because the hull form is not suited to heavy seas.

Type 312 became operational in the early 1970s, and by 1986, 60 were in service. Reportedly, this class was inspired by successful conversion of several 400-ton *Lienyun*-class auxiliary sweepers (trawler type) to remote control.

DENMARK

A Danyard GRP torpedo-recovery vessel is to be the basis for a 2-boat drone MCM system for the StanFlex 300s. Each robot boat will tow its own TSM 2054 sonar. For classification and disposal the StanFlex will carry its own tethered underwater vehicle (which had not yet been chosen early in 1991). The robot boats are being lengthened (as compared to their prototypes)

from 16.2 to 17.7 m (the displacement increases from 23 to nearly 30 tons). Pump-jet propulsion will probably be chosen to minimize their noise signature at 12–15 kt. Trials of the drones were to begin in February 1991.

FINLAND

◆ Fiskars Sweeps

Fiskars Elesco supplies a magnetic sweep to the Finnish and Swedish navies, and in 1986 the company supplied the sweep for the 2 modified tripartite sweepers built for Indonesia. The entire system weighs 2.5 tons and is intended particularly for use against mines on a rocky seabed. The magnetic sweep can be combined with an acoustic sweep to form FIMS (Fiskars Integrated Minesweep System), in which a 16-bit microprocessor (with 1 Mbyte of memory) stores a series of up to 256 waveforms corresponding to different ships, controls both the acoustic and magnetic sweeps, and monitors mine detonation (which shows whether the applied field is sufficient).

This sweep uses a Fiskars-developed computer program to define the shape and strength of the sweep field, which varies with electrode current and spacing, the depth of water, and other conditions. The program prints out equipotential curves for the 3 field components and provides the operator with the strength of the field at the seabed. Mine detonations can be marked on the simulation curves so that the characteristics of enemy mines can be estimated in greater detail after sweeping. This system uses a special small-diameter sweep cable to minimize the reel diameter (600 mm in diameter) and to permit sharp turns by the sweeper. The manufacturer claims that its system is particularly simple to operate and can be launched by 2 people in 10 min.

FIMS is a combined sweep trailed from a single winch. Its MRK-500 magnetic component is a 500-m floating cable, from which 3 electrodes are suspended.

The Indonesian sweepers have Fiskars F82 magnetic sweeps, plus Swedish (SA Marine) AS.203 acoustic sweeps and the standard tripartite Oropesa sweep (OD 3).

◆ Kiskii Class

The Drone 17.7-ton GRP minesweepers are operated either by crews or by remote control from *Kuha*-class inshore minesweepers. They tow F82 magnetic sweeps and can also counter acoustic mines. Dimensions: 15.18 × 4.10 × 1.20 m (20 tons at full load). They are powered by 2 Valmet 611 CSMP diesels and propelled by water jets (presumably chosen for their reduced acoustic signature). Seven (1 trials unit and 6 operational, 1 per minesweeper) were delivered in 1983.

FRANCE

The Evac processor in French mine-countermeasures craft is to be modified to accept GPS satellite navigational data. This system will not replace the current Syledis but will permit overseas deployments of mine-countermeasures forces when shore stations cannot be emplaced.

◆ French Sweeps

(i) Oropesa (Wire Sweeps)

OD 1 on coastal sweepers.

OD 2 on inshore minesweepers.

(ii) Magnetic

MB 1 through MB 4 symmetrical loops for coastal sweepers.

MB 5 and MB 6 asymmetrical loops for ocean and coastal sweepers. MB 5 uses a 225-kW or 364-kW sweep generator.

(iii) Acoustic

AM 1 and AM 2 hammer (*marteau*) sweeps.

AM 3 and AM 4 MF hammer sweeps for coastal sweepers. AM 3's dimensions are 856 × 520 × 340 mm; weight is 45 kg.

AP 4 acoustic sweep, covering both the low and intermediate frequency ranges. (Direction des Constructions Navales)

AP 1 and AP 2 piston sweeps for LF. AP 1's dimensions are 1130 × 558 × 380 mm; weight is 105 kg.

AP 4 acoustic sweep, announced in 1972. It combines the capability of older LF and MF towed loop systems in a single body without any surface float. Total weight is about 2 tons. This device is to equip the next-generation French minesweeper, the BAMO (*Bâtiment Anti-Mine Océanique*), and AP 4 was tested in that role in 1980–84. Compared to the British Osborn, AP 4 is said to cover a wider frequency range by using an electrodynamic (rather than hydraulic) noise generator.

AE 1 explosive sweep.

◆ Minehunting Laser

Thomson Sintra is developing a blue-green minehunting laser. The prototype is reportedly effective to a depth of 50–200 m [160–660 ft], depending on water conditions. Resolution is reportedly several centimeters at a depth of 150 m.

◆ DUBM-20 (TSM 2020)

The first French minehunting sonar incorporates both search and classification sonars. The entire dual transducer is stabilized, and the console shows both radar and sonar coordinates superimposed, for accurate mine location. Typical performance gives detection at 300 m and classification at 130 m. The detector's frequency is about 100 kHz (variable within 20 kHz, 7.5 kW), and the classification frequency is about 400 kHz (variable within 30 kHz, 4.5 kW).

A DUBM-20A upgrade program, announced in 1984, incorporated 4 main improvements: coherent processing (for better range in noisy conditions), sweep-to-sweep integration (for a clearer display), a performance indicator (to measure bottom reverberation), and a multi-image memory (to make classification easier).

Work began in 1963, and a DUBM-20X prototype was tested on board the ocean minesweeper *Narvik* in 1967. As a result of the success of these trials, the *Circe* class was built and equipped with DUBM-20A. The first such sonar was installed in 1970 (trials 1971).

◆ DUBM-21 (TSM 2021)

Derived from DUBM-20, DUBM-21 is the successor sonar. It was first installed (as TSM 2021A) on board 5 French ocean minesweepers converted to minehunters, a program begun in 1974. Compared to DUBM-20A, DUBM-21 is much smaller and more reliable. This sonar (TSM 2021B version) plus the TSM 5730 doppler sonar log (for position keeping) are the standard sensors of the tripartite (French, Belgian, Dutch) minehunter. This sonar is also the basic element of the IBIS III minehunting system. DUBM-21 uses 2 arrays to provide simultaneous detection and classification. This technology led in turn to the U.S. SQQ-32. As of 1988, the program called for the production of 40 DUBM-21s.

Mine classification is by 2 methods, shadow and direct echo. Echo classification alone cannot be sufficient because the signatures of many mines are unknown (and the echo classifier

DUBM-21B (TSM 2021) array (*Eridan* or *Tripartite* class). (Thomson Sintra)

DUBM-21 arrays and consoles. (Thomson Sintra)

generally does not provide an image immediately recognizable as a mine). Moreover, an irregular seabed may mask the echoes of a small mine. Shadow classification can reveal the shape of a mine, even if it has been designed to be nonreflective. On the other hand, it is not clear whether a shadow sonar can reliably detect deep ground mines. DUBM-21 is, therefore, designed to provide both echo and shadow classification: a conventional echo detector with a range of 100–500/600 m; and a shadow classifier imaging the seabed at 100–170 m, providing images even at 200 m, and having the capability, in theory, of identi-

Detector and classifier displays (DUBM-21 sonar). (Thomson Sintra)

fying 0.2-m² objects. Both transducers are roll- and pitch-stabilized. They are not dome-housed, to avoid any distortion of the beam; at low hunting speed (4 kt), it was believed that cavitation around the transducers would have only a negligible effect.

Both transducers used preformed beams. The long-range beam (100 kHz) is 1.5 deg wide and can sweep through 30-, 60-, or 90-deg sectors. The beam uses FM pulses 0.2 or 0.5 msec long; and the range scales are 400, 600, and 900 m. Source level is 110 dB (120 dB at maximum power). The transducer has 32 staves (each of 6 elements), and it produces 20 preformed reception beams. Their output is shown on a 16-in PPI showing a 30-deg sector, with 100-m range markers.

The shadow (classifier) beam covers either a 3.5- or 10-deg arc and is 0.17 deg wide. The beam can be depressed from –5 to –30 deg. It operates at 420 kHz (± 15 kHz), using the same pulse widths as the search sonar, with 200- and 300-m range scales. Source level is 122 dB at maximum power. There are 80 preformed reception beams (from 64 staves, each of 6 transducers). Data are presented on a rectangular CRT, and the operator can mark mine images.

♦ DUBM-40A (TSM 5420)

This small towed mine-detection sonar is for use from standard naval launches and has an 80-m [262-ft] cable. DUBM-40A emits 100-microsec pulses at 735 kHz (1 kW power). Range

scales are 40, 80, and 120 m. The transducer rotates at 3, 6, or 9 deg/sec, either continuously or by 5-, 10-, or 15-deg sectors. There are 2 displays: panoramic (PPI) and rectangular. Directivity: in bearing, 22 min; in elevation, 45 deg. The standard naval launch that tows DUBM-40A is $14.87 \times 4.14 \times 1.18$ m, weighs 18 tons, and is capable of 9 kt on diesel power. The sonar fish and cable weigh 196 kg [432 lb], and the console inside the launch weighs another 185 kg [408 lb].

A modified version, DUBM-40B, was designed for use by launches, hovercraft, and hydrofoils; it can also be used for wreck surveys. Total weight is 2055 kg, which compares to 4500 kg for DUBM-21A.

◆ DUBM-41

This towed side-scan sonar displays its data in real time on board the ship. The French navy towed this sonar from U.S.-supplied MSO-class minesweepers equipped with the UQS-1D search sonar; DUBM-41 functioned as a classification sonar. The French view was that such a combination was much inferior to a single integrated sonar such as SQQ-14 or DUBM-20.

The sonar fish is 3.7 m [146 in] long and weighs 350 kg [771 lb]. It emits 200-microsec pulses at 735 and 785 kHz (750 W), and range is 45 or 75 m to each side. If 2 fish are used (50 m [164 ft] apart), a total sweep width of 200 m [220 yd] can be achieved. The fish is held at a depth of 5–60 m [16–197 ft], and speed is 5 kt. The towing cable is 115 or 120 m [377 or 394 ft] long, each fish being held down by a kite. The height of an object can be determined within 0.5 m. Directivity of the beam is 35 deg vertically, 15 deg horizontally.

The display is either a persistent-image CRT (TEI) or a pen-marked paper (ALDEN). Typical mine classification range is 60 m.

This sonar is very similar to the U.S. Shadowgraph of the 1960s, except that DUBM-41 has 3 bottom-looking sonars to keep it clear of underwater obstacles.

The DUBM-41B fish. (Direction des Constructions Navales)

◆ DUBM-42/IBIS 42

This side-looking sweep replaces DUBM-41, for future French minesweepers (BAMO). Tow speed is greater (10 vs. 4 kt), maximum depth is greater (300 vs. 100 m), and maximum detection range is increased (150 vs. 50 m). Unlike DUBM-41, DUBM-42

uses multiple preformed beams, and 1 rather than 2 vehicles are required. DUBM-42 can cover almost 10 times the area in a given time.

The system built around DUBM-42 is IBIS 42. IBIS 42 is described as a surveillance system, mapping Q-routes in peacetime so that any changes (i.e., bottom-laid mines) can be detected rapidly in an emergency. The fish carries a TSM 2051 sonar, for shadow classification of objects in its path, and a multibeam side-looking sonar (TSM 2054). The latter can cover a 200-m track at 12 kt, providing a high-resolution (20 cm $\times$ 10 cm) picture of the sea bottom. An associated hull sonar, TSM 5421, is used to detect moored mines so that the hunter can avoid them. IBIS 42 feeds its Q-route data into a land-based processing center, which compares each survey with previously held data. A minehunting map is created in 2 steps. First the sonar image is updated, then the image is used to generate a synthetic map. Processing consists of bottom-image processing, extraction of any new echoes, location, correlation, and updating of the reference picture.

◆ DUPM-1

This hand-held minehunting sonar for divers operates in both active and passive modes and enables a clearance diver to find a mine in disturbed or muddy water. DUPM-1 uses a conical reflector with the controls on its back. Power is provided by nickel-cadmium batteries (good for 50 hr), and range is about 200 m. Overall diameter is about 12 in, for a 9-deg beam (FM slides at 50–90 kHz). The operator listens to beats between the transmitted and received beams; the beat frequency is proportional to the time difference and, therefore, to the range, since the returning signal comes from a different portion of the FM slide. Range scales are 2–22 m, 20–90 m, and 60–200 m. In each case the audio frequency range is 250–2500 Hz. This sonar can also listen for a sonar beacon that is laid to mark either an area to be cleared or a suspicious object (37–41 kHz, tuned manually). The beacon, operating at 38 kHz, lasts for 500 hr and can be detected at 500–1000 m [550–1090 yd].

◆ Buried-Mine Hunting

Two alternative sonars to detect buried mines were shown at Bourget Navale in October 1986. They are the fruit of discussions among British, French, and Dutch companies begun about 1982; and at the time of the show a trilateral MoU was expected.

British Aerospace and Thomson Sintra proposed an LF towed sonar, which might be accommodated in a DUBM-41 body, and which would use a flexensional transducer. To some extent this approach was proven during the hunt for the *Titanic*, an LF sonar on board the SAR vehicle giving an image of the composition of the ocean's floor down to 1000 ft.

DRET (*Direction des Recherches, Études, et Techniques d'Armement*) is supporting a project using a 10–50-kHz sonar, which is suggested as a compromise between LF (which penetrates deeply but has poor definition) and HF (no penetration, high definition for mine classification). The array shown consisted of 8 staves in star formation, each carrying 3 spot transducers, and the electronics would concentrate the beam on the bottom. Maximum penetration would be about 3 m.

◆ Petrel (TSM 5424)

This Thomson Sintra surface-ship mine-avoidance system was announced at Bourget Naval in October 1990. It uses the TSM 5424 preformed-beam mine-avoidance sonar. Petrel is designed for both major combatants, which may have to transit mine fields, and mine-countermeasures/surveillance units employing towed sidescan sonars, which have no way of detecting mines in their path. Petrel can also be used to evaluate mine density and risk, to mark safe channels, and to conduct preliminary operations prior to minehunting.

◆ SAR

Thomson Sintra's advanced towed imaging sonar is effective down to 6000 m. This sonar was used to locate the *Titanic*. SAR

would have naval applications in deep minehunting, and its characteristics give some idea of what really deep sonar imaging requires. The sonar, which is positively buoyant, is towed by a heavy (2.5-ton) depressor. In survey configuration, the towed body (1 × 5 m [39.4 × 197 in], 2.3 tons) carries a pair of side-scanning sonars (range 600 m to either side) and a bottom-penetrating echo sounder. The sonar operates at HF (190 kHz port, 170 kHz starboard) with a 0.5 × 80-deg beam; the transducer is 914 × 63 × 43 mm [36.0 × 2.4 × 1.7 in].

◆ TSM 2022

Thomson Sintra's single-array hull-mounted commercial minehunting sonar is designed to detect mines at ranges of 500–600 m and to classify them at up to 250 m; this performance is achieved at water depths of 10–90 m. The sonar can also measure the depth of moored mines and can conduct channel searches in the side-scan mode. For minehunting, TSM 2022 is part of the IBIS V system with the TSM 2060 automatic plotter.

The single array, which is stabilized in roll and pitch (15 deg in pitch, 5 deg in roll), feeds 1 console; detection and classification must, therefore, be carried out consecutively. For detection, the sonar covers sectors of 14, 28, or 60 deg, the last requiring mechanical rather than electronic scanning. These sectors can be steered ±175 deg from the bow. Range scales are 50–500 or 50–1000 m. For classification, the range scales are 50–150 or 50–250 m, and a 7-deg sector is covered, steerable ±175 deg from the bow. Classification is either by shadow or by direct echo.

The transducers are arranged in a horizontal linear array, which can be tilted into the vertical position for depth-finding (e.g., of moored mines). The array has 2 beamwidths, 0.37 deg for search and 0.17 deg for classification. Either the search or the classification mode can be used for depth finding. The array can be turned broadside to an expected mine position, or turned to look down, the array can be used to profile the bottom over a 14- or 28-deg arc.

Minehunting is possible at up to 6 kt; mine avoidance, at 10 kt; and side-scanning, at 10 kt. The sonar is credited with a mine-position accuracy of 1 m [3.28 ft]. In the classification mode, resolution is 0.16 deg, and range resolution is 0.15 m. Thomson Sintra claims a 90% probability of detection of a 1 m² target (ground or moored mine) at ranges from 100 to 500 m. With the array vertical, a moored mine 5 m [16.4 ft] below

the surface can be detected at 300 m [about 330 yd]. Objects as small as 0.5 m² [1.6 ft²] can be classified at up to 170 m [about 186 yd].

TSM 2022 was designed for smaller ships (hence the reversion to a single array). In all, 21 have been sold to 6 navies; this is the minehunting sonar of the Swedish *Landsort* class. TSM 2022 is the 4th generation of Thomson Sintra minehunting sonars, counting from the DUBM 20 of about 1970 and including DUBM 21A and 21B (IBIS 41A and 41B).

◆ TSM 2023

This multiple-frequency multifunction sonar is the core of the new IBIS VII system, which is intended to hunt deep (rising) mines. TSM 2023 is based on R&D work done for the classification element of the U.S. SQQ-32. It is intended to provide simultaneous detection to a range of 1200 m (at 35 kHz) and classification (at 300 m, at 250–525 kHz), and it will also be used to guide a mine-disposal device. The displays are Colibri consoles.

◆ TSM 2060 (NAVILOT)

Thomson Sintra's minesweeping tactical system is the basis of the IBIS III and IBIS V systems. TSM 2060 is a tactical plotter based on the 15M05 computer. The display is a 22-in, 4-color, circular CRT showing both symbology and raw video (for navigation among land areas). Planned and actual ship track are shown, together with up to 256 contacts. All data are recorded for later comparison with previously recorded data.

◆ TSM 2061

Thomson Sintra's tactical display (navigation/plotting system) for the IBIS 43 minehunting system (in which it is combined with a TSM 2054 towed fish) contains 2 × 19-in, high-resolution, color, raster-scan screens; a computer using 68020 chips; a removable hard disk; a keyboard with a trackball; a printer; and an X-Y plotter. TSM 2061 can also replace TSM 2060 in IBIS V.

◆ TSM 5420

Thomson Sintra's small-craft dipping search sonar is capable of displaying and classifying small seabed objects at depths as great as 300 m [984 ft].

◆ PAP 104

PAP 104 (*poisson auto-propulsé*) was the first of the modern series of unmanned minehunting/minekilling submersibles. PAP was developed by ECA for the French navy, to a requirement set by GESMA (*Groupe d'Études Sous-Marines de l'Atlantique*). GESMA wanted a mine-disposal device that could operate up to 500 m from a ship, in water between 10 and 100 m deep, for up to 20 min on station. The device had to be silent and almost entirely nonmagnetic to avoid setting off influence mines, and it had to be small and inexpensive so that it could be used in large numbers by small minesweepers. Because PAP 104 replaced the usual mine-clearance divers, it had to be able to operate in conditions too severe for them, particularly in water with 4-kt current and in a force-4 wind. Finally, because the device was unmanned, it had to transmit to the controller on board ship sufficient information to make the identification of a supposed mine reasonably certain, by means of some type of image.

The fish was, therefore, designed to carry an underwater television camera and an associated floodlight. Propelled by on-board batteries, the fish had sufficient energy for five 20-min operations before recharging. The fish's speed, about 5 kt, was set by the requirement to operate despite a 4-kt current, and propulsion was by 2 podded electric motors. Because they could be controlled independently, the fish could turn sharply. There was no depth control as such. However, the fish, which was slightly heavier than water, had a guide rope hanging from it. When the rope hit bottom and began to drag, the weight that must be supported by the buoyancy of the fish was reduced

TSM 2022 array. (Thomson Sintra)

A mine and the PAP 104 vehicle on the main minehunting sonar (classifier) display of a French minehunter. (Thomson Sintra)

PAP 104. (Direction des Constructions Navales)

enough to allow it to hover. Similarly, when the operation was over, the guide rope was dropped and the fish, which was now positively buoyant, surfaced. An on-board gyroscope kept the fish on course.

PAP was tracked by the shipboard minehunting sonar, using an on-board transponder in the sail atop the hull. Once PAP had been guided into position, the operator on board the minesweeper could fly the device into place, examine the supposed mine, and set a 100-kg demolition charge. In very poor visibility the destruction charge could be dropped by sonar alone; the

sweeper's sonar would probably give an accuracy within 2 m [6.6 ft]. After all, the purpose of the fish was not so much to ensure accuracy as to identify the object to be destroyed, so that ammunition (and time) was not expended wiping out bottom junk. The demolition charge was fired from deck, by acoustic signal (a small grenade), after the fish had been retrieved (typically 15–30 min after the charge had been laid).

Launching took about 5 min, and refitting between operations (replacement of guide rope, new guidance wire, new charge, battery replacement) took about 15.

The original version had a radius of action of 500 m [550 yd] and could run at either 80 m ("GESMA," i.e., French navy, version: 262 ft) or 300 m ("civil" version: 984 ft). Speed was 2, 4, or 6 kt; and weight was 700 kg. Endurance was 3 hr at 2 kt. This version was intended solely to attack ground mines; it had no cutters to deal with mine mooring cables.

The first production version, for the French navy, was Mk 2 (1975), made of formed aluminum rather than the sheet metal of the Mk 1 prototypes. Production cost was reduced by using standard car-type batteries and a commercial television camera.

Mk 3 was designed for reduced magnetic and acoustic signatures, as well as reduced corrosion. Mk 3 was the first export model. Mk 3s for the Royal Navy were built of nonmagnetic materials (other Mk 3s are degaussed).

PAP Mk 4 (1983) could operate at depths of 300 m rather than the 120 m of earlier models. Although the Mk 3's hull could withstand the greater pressure, the earlier motors could not; Mk 4 has new motors (which can operate at a greater depth, using electronic commutation rather than brushes) for a speed of 5 kt. The principal sensor is either a high-resolution short-range sonar or a low-light television. Mk 4 was developed specifically for the Malaysian navy, which wanted to be able to hunt mines at a greater depth.

Mk 4 has a high-data-rate cable developed for the German navy, which wanted to use a Krupp-Atlas AIS 11-104 high-resolution short-range sonar instead of the usual television camera (for poor visibility). The sonar can acquire targets at up to 20 m, beyond television range. Although the Royal Navy also operates under conditions of low visibility in the water, the RN has preferred the low-light-television version of PAP 104.

Finally, Mk 4 introduced a cable-cutter, to attack deep-moored mines.

PAP Mk 5 is the current version. Maximum speed is 6 kt, and maximum depth is 300 m. Maximum distance from the launching ship is 600 m, and endurance is five 20-min missions. The fish is modular, carrying alternative heads (user's sensors; a long-range relocation sonar; or a short-range classification sonar, the Krupp-Atlas AIS 11); alternative payloads (2 moored mine cutters, 1 on either side; the 100-kg mine-disposal charge; a manipulator with a TV; a high-capacity cutter; or ballast for mid-water navigation); alternative forms of propulsion (standard variable-pitch propellers or MG motors with electronic commutation, for increased power and depth and reduced acoustic/magnetic signature; or vertical thrusters); alternative control cables (standard 1000-m [1090-yd] blue wire; a wider-band 1000-m green wire; or a 2000-m [2200-yd] red fiber-optic wire); alternative energy source (sealed battery; high-capacity storage battery; or power drawn through the control cable); and alternative means of depth control (guide cable with variable-length control or manipulator guide cable with variable-length control). Dimensions are 120 cm in diameter $\times$ 2.7 $\times$ 1.3 m; total weight including charge is 700 kg (800 kg for Mk 5) [47.2 $\times$ 106 $\times$ 51.2 in; 1542/1763 lb].

This system, developed and built by ECA, is currently in service in the Australian, Belgian, British, Dutch, French, German, Indonesian, Malaysian, Norwegian, and Yugoslavian navies; over 325 PAP vehicles have been sold. PAP-104 has been used operationally in the Falklands War, in the Red Sea (1984), and in the Persian Gulf.

In Royal Navy service, PAP 104 Mk 5 is designated RCMDS (remote-controlled mine-disposal system) Mk 2 (Mk 1 was an earlier PAP version).

(ECA)

◆ IBIS III

The minehunting combat system of the tripartite minehunters (a version of Skubermor II, see below) has also been adopted by the Royal Norwegian Navy. It uses the DUBM-21 sonar and the TSM 2060 TDS.

◆ IBIS V

Thomson-CSF's minesweeper combat system was announced in 1980. IBIS V incorporates the TSM 2022 sonar and the TSM 2060 22-in 4-color tactical display. The action display shows the ship's track and the contact's location; the operator can record and display positions of minelike objects such as obstructions on the bottom. Similarly, the operator can compare the current situation with previously recorded runs. The display shows a 100-m safety circle around the minesweeper/hunter, so that it does not come too close to a suspected mine while investigating it. Ten previous contacts can be recorded and displayed.

Typically IBIS V includes a Thomson Sintra doppler bottom log (TSM 5721 or 5730).

Compared to IBIS III, IBIS V weighs 1.4 rather than 6 tons.

The Mk 2 version incorporates the new Colibri console, used by both the sonar operator (one 19-in display) and the tactical officer (who has 2 screens). It provides computer-aided detection and classification and includes a sonar-performance indicator.

This system is on board modified Indonesian Tripartite and Malaysian and Nigerian *Lerici*-class minehunters.

IBIS V minehunting system shows the shadowing effect of mines illuminated by an overhead sonar. (Thomson Sintra)

◆ IBIS VII

IBIS VII is a self-propelled sonar fish for the *Narvik*-class ocean minehunter (BAMO). Under development by DCN, the fish is fitted with TSM 2023. Alternatively, the sonar could be fitted in towed form, to function either as a VDS or (housed) as a hull sonar. When towed, the sonar can operate down to a depth of 200 m [about 660 ft] but at a trailing distance of less than 150

IBIS VII mine-detection display, showing synthetic video to indicate mine positions. (Thomson Sintra)

IBIS VII mine-classification (shadow image) display. (Thomson Sintra)

m abaft the ship. The sonar can operate at ship speeds of up to 5 kt, and its depth is automatically controlled. In self-propelled form, the fish can operate up to 600 m ahead of the using ship, down to 300 m in depth [about 1000 ft], and at up to 6 kt. The fish's course is automatically controlled. In either form, TSM 2023 can operate in sea-states up to 5. The sonar is designed to detect and classify targets simultaneously, at long range, operating at several frequencies. Classification is either by echo (image) or by shadow, and both detection and classification are computer-aided. Operating mode is selected with the assistance of a performance-prediction system.

(Below) A Sterne I integrated mine-countermeasures tow, consisting of a noisemaker flanked by 2 solenoid fish. (Thomson Sintra).

Thomson Sintra describes this sonar as suitable, then, both for escort missions in moored fields, where it functions as an evasion aid, and for transit and operations in shallow waters, where it would be faced with bottom mines. DCN-Thomson Sintra-Bertin are the manufacturers, and IBIS VII is to replace DUBM-42. IBIS VII is in the early development stage.

◆ IBIS 43

In 1989 Thomson Sintra announced the IBIS 43 minehunting system, developed from the earlier DUBM 41 and IBIS 42 (DUBM 42). The sensor is the TSM 2054 high-resolution multibeam side-scan sonar, mounted in a fish towed at 4–15 kt, covering 5.4 km²/hr. The fish operates down to a depth of 200 m [660 ft], sweeping a 50- or 100-m-wide [55 or 110 yd] swath (resolution cells are 20 × 10 cm or 20 × 20 cm, depending on range). The operator programs the fish to fly at a fixed height above the seabed, using its on-board echo sounder. The fish also carries an obstacle-avoidance sonar, which enables the fish to fly over 10-m [33 ft]-high obstacles. It carries a doppler sonar for precise speed measurement. The system automatically corrects the fish's speed, yaw, and pitch and computes the precise position of the towed body to an accuracy of better than 9 m. The system has 2 Colibri consoles, for sonar display and tactical control.

IBIS 43 has been chosen to equip the Danish StanFlex 300 corvettes in their Q-route (600 yd wide) surveillance role, using 2 remote-controlled 15-m craft, each towing a fish at up to 15 kt. Each craft covers the channel of interest with 3 overlapping runs to maximize mine-detection probability, each operator seeing the same object 2 or 3 times from different angles. The corvette carries a remote-controlled fish for mine disposal. The Danish IBIS 43 includes the TSM-2061 tactical data-handling system.

◆ Sterne I

Sterne I is a complex acoustic/magnetic sweep designed to mimic some of the detailed structure of a target's signature. Sterne I is analogous to the British Sea Serpent. The sweep employs 2 magnetic bodies (solenoids) and 1 acoustic body (the standard French navy AP 4), the 2 solenoids lying to either side of, and slightly ahead of, the AP 4. Alternatively, a linear configuration, e.g., of 6 solenoids and 1 AP 4, can be used against mines so sophisticated that fidelity to the ship's signature is more important than swept width. Solenoid power is supplied by an electronic amplifier that can adjust power to the level and shape of the desired signature. The manufacturer, Thomson Sintra, claims that it can achieve a large magnetic sweepwidth even using low electrical-power levels.

(Above) The linear Sterne I tow, intended to mimic a ship's detailed magnetic signature. (Thomson Sintra)

◆ Skubermor

Skubermor is the French series of minesweeping systems; the Breton name means sweeper of the sea. All versions consist of a detection/classification sonar, a means of identification and neutralization, and a means of precise navigation. Skubermor I, in the minehunter *Circe*, uses the DUBM-20 sonar, an EVEC 10 plotting table, radar and Ragep-Toran for navigation, and PAP 104 and divers for mine classification and destruction. Skubermor II, in the converted ocean sweeper *Dompair* (now discarded), used the DUBM-21 sonar, an EVEC 11 plotting table, and the same means of navigation and mine destruction (plus the American wire sweep originally supplied with the ship). Skubermor III, in the tripartite minehunters, uses an EVEC 20 plotting table, radar, Syledis-Toran or Decca (in Dutch and Belgian ships) for navigation, PAP 104, divers, and the lightweight wire sweep OD 3.

The EVEC (*Ensemble de Visualisation et d'Enregistrement de la Chasse Aux Mines*) automated plotting table is installed in the minehunter's CIC. EVEC 20 includes automatic navigational radar input. Toran and Syledis are radio navigation systems using the HF and VHF bands, respectively; the Decca system is Hi-Fix.

GERMANY (WEST)

◆ DSQS-11

The current standard German minehunting sonar is also found in the new Australian *Rushcutter* class and on the last 4 Swedish *Landsort*-class minehunters (replacing the Thomson-CSF TSM 2022). DSQS-11 uses a 90-deg horizontal beam with overlapping sweep sectors to port, starboard, and straight ahead, all 90 deg wide. The sonar can be depressed to measure a target's depth. DSQS-11 has a variable pulse rate and uses a PPI display whose video is processed to suppress noise returns.

DSQS-11H is a hull sonar in a retractable dome. This version consists of a cylindrical detection array and a flat classification array trainable through 130 deg in azimuth. Simultaneous coverage of a 90-deg sector (in azimuth) is provided by RDT of 45 pulses, with 45 preformed receiving beams, each 2 deg wide. The detection sector can be switched to any 1 of 5 preset center bearings 72 deg apart, the sectors overlapping by 18 deg. Classification is in 2 stages: first depth, then shape; up to 5 classification images can be stored. Operating frequency is 103 kHz, using 1-msec FM pulses for detection and 0.1-msec CW pulses for classification. The flat array is square, for a narrow beam; the cylinder is relatively shallow, presumably to form a fan

beam. The full array projects 0.9 m below the keel, and the assembly above it is 2.5 m high. The cylindrical array transmits 45 preformed fan beams for detection (search); the flat array transmits 20 vertically stacked beams within a 2-deg horizontal width. This sonar equips the RAN *Bay*-class minehunters, the Thai navy M48s, and the West German Type 332s.

Experience with the original DSQS-11H has apparently been less than happy. The Royal Thai Navy has had to use its new minehunters as patrol craft, retaining older U.S.-built "Bird"-class sweepers with UQS-1 sonars for mine countermeasures. Reportedly, it is planning to buy a new minehunting sonar, probably a Thomson-CSF type. The Royal Australian Navy, too, has been unable to use DSQS-11H effectively. Reportedly, as of mid-1989 it had not yet accepted the first of the new minehunters because of the unsatisfactory performance of the detection element of the DSQS-11H sonar. The RAN will probably seek trials of alternative systems by 1991. The German navy is replacing DSQS-11H with a new version, DSQS-11M. Reportedly, the problem was undue reliance on electronic scanning, a technology with which KAE had been very successful in lower-frequency submarine sonars.

◆ Penguin A1

Penguin A1 was the vehicle from which B3 was developed. A1 is now being used as the basis for a mine search/classification vehicle without mine-destruction capability. At present this phase of minehunting takes much longer than actual disposal. The search/classification vehicle can be lighter than a full minehunting device and can operate in tandem with a mine destroyer. Dimensions are 1.0 m (diameter) $\times$ 3.7 m $\times$ 2.0 m (span) [39.4 $\times$ 145.7 $\times$ 78.7 in]; weight is about 2 tons; and diving depth (hull strength) is 200 m [656 ft]. Propulsion is by a shrouded propeller at the tail, for a speed of up to 7 kt. The vehicle maneuvers with flaps set into the trailing edges of the 2 delta wings and with a vertical flap in the fin.

Normally, Penguin is powered through a cable run from the minehunter. However, the vehicle can also operate from a catamaran buoy carrying a small motor/generator unit. The fish tows the buoy, and in this form Penguin can operate for up to 10 hr. The buoy is used as 1 terminal of a radio data link with the minehunter, the vehicle operating much farther away than is common in other underwater vehicle systems.

Penguin A1 is expected to become operational in its role in the 1990s. A1 will probably carry a side-scanning sonar that will replace a similar sonar streamed by a minehunter.

Work on the Penguin series began in the early 1970s, and at that time layouts for B3 and for B6, for offshore work, were developed. Design of a model of B3 for engineering development began in 1979, based on experience already gained in the Type 331 minehunter program.

◆ Penguin B3

This mine identification-and-disposal vehicle was part of the Type 343 minehunter program. Like PAP 104, B3 is powered by motors fed by on-board batteries, in this case silver-zinc units giving 150 min of endurance at 6–8 kt. Propulsion is by twin podded units. The high speed was chosen because of the strong currents in German coastal waters; the vehicle can also hover. It turns by controlling the thrust of the 2 motors, and it climbs and dives by manipulating elevons in the wash and by using a vertical propeller in a tunnel. The gyro-stabilized vehicle is launched along a preprogrammed path to a point selected by the minehunter's combat system, and this degree of self-control reduces the operator's workload. Penguin is brought into a hover over the location of the presumed mine, then uses television (which looks both ahead and down) or high-definition (2 MHz) sonar. The sonar's range is about 10 m, and the beam is focused using an acoustic lens. Alternatively, Penguin can be fitted with a Krupp-Atlas high-definition (but lower frequency) sonar. The cable link with the controlling ship carries 3 sets of signals: a 2-way digital data link for commands and feedback, a sonar link, and a television link.

The B3 body is slightly positively buoyant, to facilitate recovery. However, this buoyancy is small enough so that B3 can fly using relatively small control forces. Thus with 30-deg-down elevon angle, B3 can reach maximum depth (from the surface) in less than 1 min.

The manufacturer is MBB-VFW. The first test vehicle was completed in 1979, a second following in 1982, with sea trials in September–October 1982, followed by trials with the minehunter *Minden* in August 1983, and trials with alternative sensors in October–November 1983.

Penguin B3. (Messerschmitt-Bölkow-Blohm)

Dimensions are 70 cm (diameter) $\times$ 3.5 m $\times$ 1.5 m (span) $\times$ 1.45 m (height) [29.9 $\times$ 137.8 $\times$ 59.1 $\times$ 57.1 in]; weight is 1350 kg [2975 lb]. Penguin B3 carries two 120-kg [264-lb] charges in tandem so that it can destroy 2 mines during a single mission. Range from the operating ship is 600–1000 m [660–1090 yd]. Diving depth is 100 m [328 ft].

◆ Troika

Troika consists of a control ship (which tows a moored sweep) and 3 drone sweepers that provide acoustic and magnetic signatures to trigger influence mines. The drones are tracked by stabilized X/C-band radar (the 3 boats are fitted with Luneberg Lens radar reflectors atop their masts), and the data link is UHF. Courses for both drones and control ship are corrected automatically. Control range is several miles. Typically, the control ship carries her own mine-detection/avoidance sonar (DSQS-11A) to detect moored mines not swept by the drones.

Each Troika sweeper is 24 m [79 ft] long and displaces about 95 tons; draft is less than 2 m [6.6 ft]. The boat has a blast-resistant steel hull (around which a wooden hull has been built), in which diesel engine, control, power supply, and remote controls are all shock-mounted. The diesel uses a hydraulic drive for shock resistance. Two coils, 1 at each end, generate a strong magnetic field to explode magnetic mines. For acoustic mines, each Troika carries 2 MF sound sources in its bow and tows an LF source.

Krauss MaK is the prime contractor.

Experiments in 1959–60 led to the construction of 2 remotely controlled sweepers, *Walross* and *Seekuh* I (Manatee), followed in 1965 by 2 more *Seekuh*, the 3 constituting the first German Troika. The coastal minesweeper *Niobe* served as control ship. In 1969, under remote control, *Walross* swept a field of World War II mines in the Tegeler Platte shallows so that a lighthouse could be built. Six Troikas (18 remotely controlled craft and 6 controllers) were ordered in the mid-1970s (the controllers were converted in 1979–81).

Krupp MAK has announced a new version of Troika, MCM-SDS (surface drone system), which is more flexible than the original and can hunt and lay mines. The drones are self-guided through a series of preset navigational waypoints (using the new very accurate navigational aids), and thus up to 4 can be controlled by a single operator. This contrasts with the previous method, in which the operator controlled a drone by steering it along a track line visible on the radar. The drones can be controlled from a ship or from shore. They are also faster than their predecessors, with greater range and survivability. Each 25-m (90-ton) drone can carry 4 alternative mission kits: for route surveillance (towing a fish with side-looking sonar), for wire or magnetic sweeping, and for minelaying. Missions are varied by embarking alternative kits; the control station does not change. An alternative single-mission drone would displace 50 tons.

A Troika boat, *Seehund* 1. (L. van Ginderen)

◆ MWS 80

Krupp-Atlas's minehunter weapons system uses the DQS-11H sonar and the PAP 104 vehicle. As applied to the Australian catamaran minehunters, the operations room itself is containerized so that it can be removed for maintenance without withdrawing the hunter herself, a second operations room being substituted.

INTERNATIONAL

◆ EPMDS

Experimental Parametric Mine-Detection System is a French-British-Dutch program to find buried and disguised mines. EPMDS uses a very stable towed fish carrying sonars, beamformers, some of the processors of the French DUBM-41, and new receiver arrays (with on-board processors) developed by British Aerospace. Trials were scheduled for 1990, on board the Dutch research ship *Tydeman*.

◆ NATO MCM Studies

NATO Project Group 22 is studying technologies for mechanical and influence sweeping in the mid-1990s and beyond, both for the deep sweeps wanted by the U.S. Navy and for coastal waters. The study of mechanical sweeping was conducted between September 1987 and May 1988; the issue was whether the full water column (2 km) could be swept by 1 system. The conclusion was that no single system could easily handle this volume because the sweep would be so heavy that a ship of destroyer size would be needed to tow it. Instead, 2 types of sweep would be required: a flying sweep using existing types of cutters, and a rolling or sliding sweep to clear bottom mines. Even so, large sweepers would be required, and the group considered using decommissioned bulk carriers and other merchant ships.

◆ ERMIS

Explosion Resistant Multi-Influence Sweep System is under development by a 5-nation consortium within NATO (France, Germany, the Netherlands, the United Kingdom, and the United States) to deal with pressure as well as acoustic and magnetic mines. The first underwater explosion trials were conducted in 1983. The idea of an unsinkable craft that would simulate the usual target dates back to World War II, and in the early postwar era the idea led to the construction of the U.S. XMAP cylindrical countermeasure and to British experiments with strings of Thames barges. In the 1950s and 1960s the United States experimented with explosion-resistant modified Liberty ships, powered either by deck-mounted turboprops or by what amounted to outboard motors.

ERMIS is conceived as an inflated fabric tube surrounding an explosion-resistant body consisting of ballast tanks open at the top and sealed at the bottom by flexible rubber diaphragms. The inflated portion of the hull carries the diaphragms above the water, to form an air space that reduces shock effects. This concept is similar to the abortive U.S. surface-effect minehunter (MSH), and the air cushion also explains why air cushion minesweeping experiments have been so successful. In the case of ERMIS, the problem is to provide a sufficient pressure signature to detonate a pressure mine without coupling the hull so strongly to the water as to destroy it.

Germany, Britain, the Netherlands, and the United States signed an MoU covering the first 2-3 yr of ERMIS development in 1978.

ITALY

The standard wire sweep is designated MIS.4.

◆ P2072

P2072 is FIAR's sonar for *Lerici*-class minehunters: see the U.S. SQQ-14 entry. This sonar is also used by the Belgian navy. The Plessey Speedscan (see the British Type 2048 in the ASW section) has been integrated with P2072 for route surveillance. A

memory has been added to the classification sonar so that up to 4 pictures can be recalled at will, either singly or together, to assist in classification. Signal processing is largely digital.

This sonar is considered effective down to 350 m (i.e., down to the continental shelf).

◆ P2095

The successor to P2072 (SQQ-14/IT) is for use at greater depths (for oceanic mine hunting). P2095 is a development of the Plessey/GE Type 2093 by FIAR, GE, and Plessey to meet Italian requirements. P2095 should enter service on board a new class of ocean minehunters planned for construction from 1993 on.

The Plessey-FIAR P2095 minehunting sonar (the towed body is shown). Operational testing is expected in 1992, with installation on board an Italian minehunter by the end of 1993. (FIAR)

◆ IMICS

The Integrated Minehunting Combat System for the *Lerici* class consists of the SQQ-14/IT sonar, SSN-714 MACTIS (Minehunting Action Information System), SPN-703 navigational radar, SSN-715 navigation and tracking system, and a precision navigation system. There are 2 IMICS displays, 1 on the bridge and 1 in CIC.

◆ MACTIS/SSN-714

Datamat's digital navigation (tactical-situation compilation and display) and plotting system is for the *Lerici*-class minehunters. The display uses a 16-in circular CRT with a keyboard and tracker ball, and the associated computer is the same Rolm MSE 14 used in the SACTIS submarine combat-data system. MACTIS is the main subsystem of IMICS, described above.

◆ MIN 77

This mine-disposal vehicle is designed for the *Lerici* class. Smaller than PAP 104 or Pinguin, MIN is powered, at up to 5 kt, by a single ducted propeller, which can be oriented in 2 planes for steering. Paired (fore and aft) vertical and horizontal thrusters work in tunnels in the body of the vehicle. For minimum magnetic signature, the body is GRP over an aluminum frame, and the use of pneumatic (actually compressed nitrogen rather than compressed air) motors eliminates the usual magnetic signature of an electric motor. The motors are fed by 5 oil-nitrogen pressure tanks, which can be topped up by an electric pump in the vehicle. Because the motors can operate at variable speed, the propellers can be fixed pitch, to minimize the acoustic signature. The vehicle can be recharged in 15 min and turned around for a second mission in 20 min.

MIN carries either an LLLTV (with underwater light) or a sonar and is powered, in either case, by on-board batteries. The sonar operates at 400 kHz with 0.05- or 0.70-msec (for, respectively, seabed or moored mines) pulses, scanning a 60-deg sector in about 2 sec. Maximum range is 20 m or 40 m (bottom or moored target). Display modes are raw video (bottom mines),

MIN 77. (Selenia)

synthetic video (moored mines), or raw video with digital range (moored mines).

The vehicle floats to the surface after it drops its acoustically fired charge.

Dimensions are 105 cm (diameter) $\times$ 3.5 m $\times$ 1.4 m [41.3 $\times$ 138 $\times$ 55.1 in]; weight is 1300 kg [2865 lb]. Maximum depth is 200 m [656 ft], and maximum operational range is 400 m [440 yd] (the umbilical cable's length is 1000 m [1090 yd]). Endurance is 40 min at 3 kt. Hovering control is better than ± 0.5 m, and the depth of the bottom can be measured more accurately than ± 0.25 m. The vehicle can operate in sea-states up to 4 and in currents up to 3 kt (along the hunting line).

The vehicle is built by a consortium, SMIN, formed in February 1978 by Elsag and Riva Calzoni. SMIN received a contract for 4 vehicles in June 1979. Tests began in 1983.

◆ Pluto

This private-venture minehunting vehicle, designed by Gaymarine, is based on the FILIPPO underwater inspection device. The fiberglass body is mounted on a steel sled frame (for ease of handling). The body in turn consists of a fixed rear section (containing batteries and electronics) and a forward section that can tilt up to 240 deg, carrying the sensors (200-kHz sonar, with a range of 30 m [98 ft] and 10-deg beamwidth, and television). Propulsion and control are by 5 electric motors: 2, inclined at about 45 deg, behind the head; 2 horizontal at the stern, for motion forward or in reverse; and 1 horizontal at the stern, to turn the vehicle. The operator uses 2 joysticks. The vehicle carries either explosive cutters or a 15-kg mine-destruction charge. Dimensions are 0.6 $\times$ 1.6 $\times$ 0.6 m [23.6 $\times$ 63.0 $\times$ 23.6 in]; weight is 160 kg, including a 40-kg charge [353/88 lb]; maximum range is 500 m [550 yd]; maximum diving depth is 400 m [1312 ft]; speed is 6 kt; endurance is 1–2 hr.

As of 1986, reported purchasers were the Nigerian navy (for 4 *Lericis*), the South Korean navy, the Thai navy, and the Italian navy (which had conducted trials with the prototype in 1982–83). The U.S. Navy has bought at least 2 units. The Spanish navy has chosen Pluto for its new minehunters (modified *Sandown* class).

Gaymarine exhibited a new mine-countermeasures submersible, Pluto Plus, at Mostra Navale in Genoa in May 1989. Compared to the existing Pluto, Pluto Plus is longer (1.95 vs. 1.6 m) and heavier (250 vs. 160 kg); Pluto Plus can operate to a depth of 400 m and at a speed of up to 7 kt (with an endurance of 10 hr). Sensors are a color television camera and 3 sonars (for search at medium range, navigation, and target identification).

◆ SSM

Gaymarine's semisubmersible minehunting vehicle operates at periscope depth under remote control (UHF data link), in up to sea-state 4 or 5. SSM carries both search (forty 3-deg preformed beams in a tiltable head, range about 200 m [656 ft]) and classification (mechanically scanned, 2 scans/sec, over a 45-deg sector, at 1.2 MHz, with a 7.5-m [24.6-ft] range) sonars. SSM can release a Pluto mine-disposal vehicle (released and recovered via a stern hatch). The Pluto can be automatically reloaded with mine-disposal charges (SSM carries 6). The vehicle is powered by 2 diesel generators, amidships, and it has 2 stern propellers (for speeds up to 6 kt) and 2 vertical and 2 lateral thrusters (1 each at bow and stern) for maneuvering.

SSM was announced in 1986, and construction of a prototype began in the fall of that year. SSM was conceived as a minehunting system for a craft of opportunity, the mother ship having no sonar.

JAPAN

The standard Japanese minehunting sonar is ZQS-2, a license-built version of the British Type 193. The -2B version is in the *Hatsushima* class. The earlier ZQS-1 was a modified U.S. UQS-1 on board 4 former minesweepers (*Kasado* class). A ZQS-3 is planned, presumably for the new minesweepers. All are hull sonars rather than VDS. The JMSDF also uses a hand-held diver sonar, RQS-1 (comparable to the U.S. PQS-1), and divers' magnetic-mine detectors (RSX-1 and -2). RSX-2 is analogous to the

S-2 (Type 71) acoustic sweep gear. (Ships of the World)

S-4 (Type 75) mine-destruction vehicle. (Ships of the World)

U.S. EOD Mk 4. The standard acoustic sweep is designated S-2. Japan also uses the U.S. A Mk 4(v) and A Mk 6(b) and the U.S. magnetic sweeps M Mk 5(a), M Mk 6(a), and M Mk 6(h). Japan uses a distinctive Type S-4 remotely controlled underwater vehicle that lays its own mine-disposal charges. S-4 has 2 thrusters with prominent motor housings, 1 at each side at the rear end, and a saucer-shaped nose with a flat dome on top. S-4 is carried by the *Hatsushima* class; the earlier *Takami* class carries 4 divers.

The Japanese FY89 budget included the first of a new class of deep-water minehunters, to employ the S-7 deep-water minehunting system and the S-8 deep-water moored sweep.

Japan also employs a helicopter minesweeping system, using KV-107s. They are now being replaced by Sikorsky MH-53Es.

NETHERLANDS

The standard sweeps (in the tripartite minehunter) are the French MDV/OD.3 wire sweep, the Finnish F.82 magnetic sweep, and the Swedish AS.203 acoustic sweep.

NORWAY

◆ Albatross

Simrad's distributed tactical system for Norwegian *Orsoy*-class minehunters and *Alta*-class minesweepers uses 6 standard multipurpose consoles. Four of them are linked by a dual Ethernet data bus: the navigational console alongside the officer-of-the-watch (OOW) console, and the mine-avoidance sonar or minehunting sonar console alongside the tactical console. A separate console for the commanding officer is linked to the sonar, tactical console, and OOW console. There is also a mine-warfare-officer console separate from the tactical console. The navigational radar or radars (3-cm, plus an optional 10-cm set) feed into the OOW and mine-warfare-officer consoles. Sources of navigational data are a GPS receiver, an inertial navigator, and the usual combination of log and gyros. Wind sensors feed directly into the navigational console. A mobile positioning system and an electromagnetic log can be available as options. The navigational console directly controls the thrusters and waterjets that position the craft. The minehunting sonar is the French TSM 2023N; the mine-avoidance sonar (in the minesweeper version) is the Simrad SA950. An unusual feature of the system is the peripheral computer connected not only to a printer and plotter but also to a digitizing board, which can insert charts into the system. It connects both to the Ethernet and to separate displays on the bridge and in CIC (Operations Room).

◆ SA950

Simrad's mine-detection and -avoidance sonar uses a retractable hull transducer. The transducer consists of 64 vertical staves, individually driven. Operating frequency is 95 kHz. It transmits in a wide (sectoral) beam and receives in digitally preformed multiple beams, over a 45-deg sector (1.7×10 -deg beams); the sector is trainable (± 190 deg) and tilts (limits $+10/-90$ deg). Train rate is 30 deg/sec; tilt rate is 150 deg/sec. Typical CW pulse lengths are 0.2–12.8 msec, selected according to search range. FM pulse lengths: 0.8, 3.2, 12.8 msec (bandwidth 5 kHz). Pulse forms: CW short, normal, and long; FM-0 (1 pulse), -1 (2 subpulses), -2 (4 subpulses), -3 (8 subpulses), and auto. Each FM subpulse is on a different frequency. For example, FM-3 produces 8 subpulses, each 1.6 msec long, each with a frequency bandwidth of 625 Hz, $\frac{1}{8}$ the total. Range scales: 75, 150, 300, 600, 1200 m. The sonar can track targets. The display is a 20-in color CRT (680×512 pixels in 8 bitplanes). The echo field is contained in a 512×512 left square coded in 6 bits (64 colors), with the right 2 bitplanes for overlay and menu. There are 3 display modes, in each of which the sonar sector is shown in a plane that tilts with the transducer: true motion, sector, and zoomed sector. True motion is north-stabilized. The current 45-deg sector is updated, while data from sectors examined ear-

lier remain on the screen. Ship's motion is taken from the speed log and gyro, and a track history is shown. Up to 8 markers can be placed on the screen. In the sector mode, the full 45-deg sector is shown (512 range arcs and the 32 beams interpolated to 64 beams). The rest of the echo field is filled with range-time data, scrolled to the right after each sweep. This mode shows the direction of the sector with respect to the ship. The zoomed sector mode is a sector with only the outer half shown, e.g., echoes from 600 to 1200 m only. Maximum ship's speed while operating the sonar is 12 kt.

SA950 has been under test on board the Norwegian "Bird"-class minesweeper *Kvina* since February 1988. Targets included both mines and submarines.

◆ SH100

This Simrad mine-detection and -classification sonar entered production in 1989. It normally operates at LF (95 kHz) for wide-sector search and target acquisition and at HF (335 kHz) for classification/localization, but the 2 modes can be interleaved. The transducer can also be set in the vertical position to classify moored mines. There are two 20-in raster-scan color CRTs. Both transmitting modes use sector transmission and form beams for reception: 32 beams, each 1.7×10 deg (total 45 deg), for search; and 64 beams, each 0.25×10 deg, for classification (total 16 deg). The HF and LF transducers are aligned together, and train within ± 200 deg; they tilt within $+10/-90$ deg. In effect, SH100 is SA950 plus two 64-element HF receiving arrays. The HF sonar uses a curved array for transmission (the LF sonar uses the same staves for transmission and reception). There are two 680×512 -pixel color CRTs, 1 (normally the top 1) for the tactical display, the other for the echo presentation. Echo data can be presented in detection, classification, or combined mode, as B-scans or echograms. Typically, the screen is split horizontally between the 2, e.g., HF echogram on the left and HF B-scan on the right (but it can also mix, e.g., LF B-scan on the left and HF echogram on the right). Each presentation can be zoomed.

SWEDEN

The Swedish Defense Research Establishment is working on underwater lasers, presumably for minehunting.

◆ 9TS700

The standard Swedish navy acoustic sweep, this BEAB acoustic projector incorporates 2 magnetostrictive and 5 ceramic transducers covering 4 acoustic bands, the intensity of which can be controlled by sweeper. Propeller modulation can be superimposed on transmitted signature. A single unit controls both 9TS700 and a magnetic sweep. The projector is 2 m long (835 kg in air, 438 in water).

◆ 9MJ400

The BEAB-Racal-Decca minesweeping direction system of the Swedish *Landsort* class is related to the 9LV series. It can control up to 3 SAM vehicles. The main sensor is the French TSM 2022 sonar, and 9MJ400 is integrated with a 9LV100 optronic FCS (which uses the electronic plot of the 9MJ400 system for target detection). This is a centralized system built around 2 computers, a main processor and a minehunting computer. The main processor feeds the displays (1 horizontal tactical console and 2 navigational PPIs). It is fed by the optronic director, target designators (pointers), the navigational radar, the wind sensor, and radio data links. It in turn is connected to the separate minehunting computer. The latter is connected to the minehunting sonar, automatic chart table, helm indicators, printer, and gyro compass. The integrated navigation and minehunting functions are based on the British Decca MAINS/CANE systems. During mine search the ship is controlled by an integrated autopilot for maximum track accuracy. The autopilot hovers it in the optimum position during mine disposal.

◆ SAM

A remotely controlled vehicle for preliminary sweep, SAM uses an integral magnetic sweep and a towed acoustic sweep and carries 8 Dan buoys to mark a cleared channel. The hull is a pair of foam-filled GRP pontoons covered by an 18×6.1 -m platform of aluminum girders, on which sits the engine casing (one 150-kW Volvo Penta TAMD 70D engine and Schottel propulsion unit). Speed is up to 8 kt, and endurance is up to 330 nm. Draft is 0.7 m (1.6 m over propeller).

The SAMs were delivered by Karlskronavarvet in 1983–86.

SAM unmanned craft. (SUTEC)

◆ Sea Eagle/Double Eagle

This vehicle, used on board Swedish M80 (*Landsort*) -type minehunters, was developed by the Scandinavian Underwater Technology Group (SUTEC) from the earlier commercial Sea Owl. The Swedish navy used Sea Owl and underwrote half the development cost of Sea Eagle.

The vehicle is built of aluminum inside a steel frame and is powered by 4 horizontal (2 athwartships, 2 lengthwise) and 3 vertical electric thrusters; power is fed through the umbilical, which also passes control instructions and data. The 350-m main sensor is a television camera. Sea Eagle is launched into the beam of the minehunting sonar and tracked as it swims to the mine. The telescopic arm carries a miniature television camera and a mine-destruction charge the last 5 or 10 m to the mine; using the camera, the operator inspects the mine to ensure that the destruction charge is in the optimum position. The charge is detonated by acoustic signal at a range of 350–1000 m.

Dimensions are 76 cm (diameter) $\times$ 1.45 $\times$ 0.58 m [29.9 $\times$ 57.1 $\times$ 22.8 in]; weight is 90 kg [198 lb] total; range is 350 m [380 yd] from ship; maximum depth is 250 m [820 ft]; speed is 2.5 kt.

The new Double Eagle was conceived to extend Sea Eagle's capabilities. It can operate in strong currents (up to 3 kt). Where Sea Eagle could take any attitude within ± 40 deg, Double Eagle can be made stable in any attitude at all (± 180 deg). Power consumption is almost 5 times that of Sea Eagle, but weight is only doubled. Payload capacity has been increased. Double Eagle can achieve more than 5 kt forward speed (3 kt backward, 2 kt laterally, 1 kt vertically; but it ascends and descends at over 5 kt). Payload is normally 30 kg, but additional buoyancy modules can increase that weight. Telemetry is provided by 4 fiber-optic links, each of which can carry 2 video/sonar channels and spare serial data channels. The standard system includes 1 external tiltable color CCD camera with remote focus and connector for an additional color or black-and-white camera; the vehicle carries drivers and power supplies for 2 video cameras. The typical sonars are the UDI and Mesotech types described in this section and in the ASW section. Dimensions: 2.05 (length) $\times$ 1.3 (width) $\times$ 0.45 (height) m; weight is approx 300 kg, with slightly positive buoyancy. Control is by 2 joysticks (forward/back, lateral, yaw; and up/down, roll, pitch) and 3 mode-control switches (power, selection of axis along which

Sea Eagle. (SUTEC)

Double Eagle. (SUTEC)

joysticks operate, and reference adjustment, to balance current or cable drag). Maximum operating depth is 300 m [about 1000 ft], and the vehicle is gyro-stabilized to within ± 2 deg. The tether (control) cable is 600 m long (a greater length can, however, be supplied).

As of early 1990, the prototype Double Eagle had been completed, and SUTEC was beginning a 1-yr feasibility study of a fully autonomous underwater vehicle.

USSR

Four or more Soviet Polnocny-A and -B-class medium landing ships are line-charge layers to clear beach defenses. These ships carry line charges in side troughs, with stern chutes to launch the 2 small remotely controlled motor boats that tow the charges into place.

The fantail of a Natya-I-class minesweeper shows, aft, biplane and triplane paravanes and an LF acoustic source. (U.S. Navy)

A Natya-I-class minesweeper displays standard Soviet medium sweep floats and biplane paravanes (vertical). The winch is used for magnetic, mechanical, and acoustic sweeping. (U.S. Navy)

The new Gorya-class ship shows standard Soviet triplane paravanes. In the background, largely hidden by the crane, is the acoustic sweep device. (U.S. Navy)

The new Gorya-class minehunter/sweeper displays an acoustic sweep device on her fantail (under the standard articulated crane). The sliding doors visible on the left may cover RBU-1200s, which are standard aboard Natya-class sweepers. They are used for countermining and for ASW. (U.S. Navy)

Soviet towed-sweep craft under tow. Each can deploy magnetic sweep cables or explosive line arrays over its stern (a tow cable is visible on board the near unit). The Soviets have several dozen of these craft.

As of 1988, the Soviets do not appear to have a mine-disposal submersible in service; their 2 *Vanya*-class minehunters carry boats, presumably for diver support. The Soviets do use a television minehunting system that lays marker buoys for later investigation of supposed mines. Published reports of a Soviet mine-disposal vehicle (SPA) seem to reflect the inclusion of such vehicles in encyclopedia articles (which describe the general state of the art, not necessarily the state of Soviet mine countermeasures).

The Soviets do have drone minesweepers (analogous to the German "Troikas"), the Ilyusha class. There are also several dozen towed sweep craft, and there is a helicopter-towed version of the Volga-class sports hydrofoil, carrying acoustic and magnetic countermeasures.

UNITED KINGDOM

Current British thinking on mine countermeasures is typified by the decision to build the steel-hull "River" class primarily to clear submarine sortie routes by disposing of mines at depths between 55 and 200 m [180 and 660 ft] because 55 m is the effective limit to deploy ground mines. The theory is that moored mines cannot have very sensitive magnetic sensors because they are subject to considerable tidal movement, so a degaussed steel hull suffices to protect against them. For shallower water, the Royal Navy relies on hunting and sweeping.

◆ Towed Sweeps

Type "O" is Oropesa, the sweep to cut mine moorings; Type "A" is acoustic; and Type "M" is magnetic. The current standard British sweeps are the Oropesa Mk 3 Mod 2 (plus a later version with GRP floats, kites, and otters, for reduced weight); the MM Mk 11 magnetic loop sweep; and the Osborn acoustic sweep (see separate entry below). In the mid-1950s the wartime electrode (magnetic) sweeps were supplanted by loop sweeps, which could be towed at relatively high speed and were easier to stream and recover. However, because the loops swept out to both sides of the sweeper, they tended to place a higher magnetic field under the sweeper. Moreover, it was relatively difficult to place an LF acoustic sweep inside a loop to trigger combined magnetic/acoustic mines.

Typically, a double "O" sweep (towed by 1 sweeper, double because 1 wire is streamed to each side) has a depth of 30 m and a swept path 265 m [290 yd] wide. Team sweep by 2 ships is with an "A" sweep, with a depth of 90 m [300 ft] and a swept path 350 m [380 yd] wide. A typical magnetic loop sweep clears a path 75 m [80 yd] wide, 400 m [about 1300 ft] abaft the sweeper.

Standard acoustic sweeps use a broad-band noisemaker covering the usual ship frequencies. More recent systems, such as Osborn, can be tuned more precisely to the expected mine-triggering frequencies.

Below are listed the wire and magnetic sweeps in service just after World War II. Although much has changed since then, the figures listed should be typical of modern sweeps. Wire lengths are in fathoms (6 ft each), and other distances are in cables (120 fathoms). Since the wires are not straight, swept paths are much narrower than the lengths of the streamed wires.

(i) Oropesa Sweeps

Mk 1 ocean sweepers. "O" sweep 300 fathoms (kite to otter), 8/8.5 kt; "A" sweep (2 sweepers, 2½ cables apart), 400–450 fathoms between kite blocks, 8/8.5 kt.

Mk 2* coastal sweepers. "O" sweep 300 fathoms, 6–9 kt; "A" sweep, 300 fathoms, 5–7 kt.

Mk 3* coastal sweepers. "O" sweep 250 fathoms, 7–8 kt; "A" sweep, 300 fathoms, 5–6 kt. Mk 3*, rather than Mk 1, is the standard "Hunt"-class sweep.

Mk 7 inshore sweepers. "O" sweep only 60 fathoms, 9–10 kt. This sweep was used by postwar inshore craft ("Ham" class).

Mk 9 deep wire sweep (EDATS) introduced 1981; see EDATS, below.

These sweeps may be prefixed W, as in W Mk 2 for coastal sweepers.

(ii) Magnetic Sweeps

LL means double longitudinal.

LL Mk 3 for coastal sweeper. Long leg 525 yd, short leg 200 yd, maximum sweep speed 7 kt, 300 yd wide in P formation (108-kW sweep current). Cycle 4.5 sec, double cycle 60 sec.

LL Mk 6* for ocean sweeper. Long leg 575 yd, short leg 225 yd, maximum sweep speed 12 kt, path 300 yd wide in P formation (220-kW sweep power). Cycle normally 3.5–7 sec, special 10 sec, double cycle 28–60 sec.

LL Mk 8 for inshore sweeper. Long leg 500 yd, short leg 175 yd, 7 kt, 200 yd wide (sweep power 35 kW using batteries).

Mod L modified Loop sweep. Three legs (575, 325, 185 yd), maximum speed 12 kt for ocean sweepers, 10 kt for coastal sweepers, 8 kt for trawlers; 125-yd-wide path.

ME means electrode sweep (this series probably superseded the earlier LL designations).

ME Mk 103 for motor minesweepers (MMS), using a 108-kW generator/battery outfit. Maximum pulse current is 1500 amps, maximum sweep speed is 10 kt.

ME Mk 106 for *Algerine*-class steel ocean sweepers, using a 220-kW diesel generator to provide the sweep impulse, with a maximum pulse current of 1500 amps and a maximum sweep speed of 12 kt.

ME Mk 107 alternative for *Coniston*-class coastal sweepers, using a 375-kW diesel generator; maximum sweep current is 2500 amps; maximum sweep speed is 12 kt.

ME Mk 108 for minesweeping motor launches, alternative for inshore sweepers ("Ham" class), using a 35-kW generator (340-kW inshore sweepers); maximum sweep current is 1200 amps; maximum sweep speed is 12 kt.

ML means loop sweep. As of 1959, the loop sweeps were standard, but some sweepers retained electrode sweeps, pending development of a convertible sweep.

ML Mk 3 for inshore sweepers ("Ham" class), using a 340-kW generator; maximum sweep current is 1500 amps, and maximum sweep speed is 6 kt.

ML Mk 4 for *Algerine*-class steel ocean sweepers, using a 220-kW generator; maximum sweep current is 2500 amps, and maximum sweep speed is 10 kt.

ML Mk 4-1 for coastal sweepers ("Ton" class), using a 375-kW generator; maximum sweep current is 2500 amps, and maximum sweep speed is 10 kt.

The current standard magnetic sweep is MM Mk 2.

(iii) Acoustic Sweeps

There were also acoustic sweeps, using both noisemakers and explosives. The latter, which may still be in use, were intended to deal with mines that could distinguish between the steady build-up of noise from a noise-making sweep and the relatively sharp build-up of the noise of a real ship.

AD (Acoustic Displacer) uses ship's 220-volt DC current to produce LF noise (10–30 Hz) in 2 ranges, depending on the size of the crank (1 in gives 10–16, ¼ in gives 16–30). This device was used on board ocean, coastal, and inshore sweepers.

AH Mk 4 (Hammer) uses ship's power (220 V) to drive 2 alternative diaphragms, either 19 in (150–1000) vs. RN mines or 27 in (60–1000) vs. German mines (during postwar mine clearance in European waters; but the Soviet KRAB was probably based on German practice).

AO Mk 4 (Acoustic Oscillator) uses a 5-kVA motor alternator to provide high-intensity narrow-band noise (235–245 Hz) against coarse mines.

AX Mk 3 (Explosive Sweep) produces broad-band noise from 100 Hz up, suitable for all sweepers, including small craft.

See also EDATS, below.

◆ Type 193/193M

Type 193 is the current standard British minehunting sonar. It operates at 2 frequencies: a lower frequency for search and a higher frequency for better resolution for mine classification. The sonar transducer, which is stabilized, is hull-mounted, and it is steerable both in train (270 deg to either side) and in elevation.

The modernized Type 193M entered production in 1976. Improvements include greater reliability and much reduced weight and volume, all consequences of adopting solid-state electronics. The most significant performance improvements were the introduction of a long (600-yd) range scale and a better beam pattern.

Because the variety of objects on the sea floor is immense, the sonar needs an unusually wide dynamic range, in this case 120 dB. However, conventional displays are limited to 20 dB, so that the sonar must be set to operate in a variety of modes: shadow, target shape, or echo structure classification. A very short pulse mode (50 microsec) shows target highlights without distorting them by overlapping.

In the shadow mode, the sonar illuminates the area behind the mine and then picks up the reflections. This technique is used in Type 162 and in the U.S. Shadowgraph. The shape of the shadow does provide evidence of the shape of the object, but in many cases no shadow can be formed (the seabed is not sufficiently reflective), or there may not be a useful shadow (as in the case of ground mines in deep water). In the target-shape mode the sonar senses the detailed structure of the returning echo. This mode is expected to be particularly effective when the mine has a rough surface, echoes coming from many points on its surface. However, modern mines are unlikely to become very rough even after lengthy immersion. A smooth mine is a poor reflector, and its shape may not show up clearly. The third mode, echo structure, works on discontinuities in the mine's projected surface. The result is only rarely an image resembling a mine, but it does make classification more accurate.

Type 193M searches at 100 kHz (16×1 -deg beam, range 600 yd) and classifies at 300 kHz (6×0.3 -deg beam, range 300 yd).

Type 193 is used by the Royal Navy (193M Mod 1 is on board the "Hunt" class), by Argentina (on board 2 "Ton"-class minehunters), by Australia (1 "Ton" class), by Germany (on board the Type 331 class), by Korea (on board the minehunters now being built), by Norway (*Tana*), by South Africa (*Kimberley*), and by Yugoslavia; it is manufactured under license in Japan. As of late 1989, 50 had been made. It will be succeeded by the AMMS mirror system, which uses Type 2093 inboard electronics.

Current improvements include the addition of a Mills Cross, which improves long-range performance against small contact (moored) mines. Up to 4 views of a target can be stored and compared for classification.

◆ Type 2034/2053

See the ASW section and Waverley 3010, below.

◆ Type 2093

Type 2093 is the Plessey/General Electric replacement for the existing hull-borne Type 193, the first of which will be fitted to the new British *Sandown*-class Single Role Minehunter. The manufacturer describes 2093 as the first variable-depth multi-mode minehunting sonar. It can operate as either a hull sonar or a VDS and has different frequencies for search and classification. The manufacturer claims a range at least twice that of a conventional hull-mounted minehunting sonar and 3 times the detection depth. Maximum speed of advance is 12 kt, compared to 3–4 kt for Type 193M.

The towed body, 1.054 m in diameter (not including vanes) and 2.521 m high; weighs 2900 kg in all. It accommodates an

Type 2093 transducers. (Plessey)

Type 2093 operation, showing the multiple sonar beams. (Plessey)

LF ring array, a VLF ring array, a VHF projector, an HF projector, a VLF projector, and an HF/VHF hydrophone, as well as a depth sounder on the underside. The manufacturer does not define these frequency bands, but even the VLF band is likely to be on the order of 100 kHz. The HF and VHF sonars are used for classification, and they share a common broad-band receiver. They use separate transmitter arrays, generating either wide or narrow beams according to the selected sonar function. The LF

height-finder uses a separate fixed-beamwidth array. The VLF transmitter uses its own array of 6 circular transducer layers, for vertical beamwidth control. The depth sounder operates at VLF.

Alternative operating modes are VLF search and moored mine classification; LF search and moored mine classification; VLF and LF search; search and ground mine classification; and search and route survey. A special height-finding sonar in the system can find moored mines, concurrently with the search for bottom mines. Two classification frequencies are available, to deal with different bottom and sea conditions.

There are 2 identical shipboard displays, each fed by a telemetry link and each capable of any of the sonar processing functions (for dual operation). Computer-aided classification circuits take expanded HF or VHF range data and provide images directly to the display consoles.

Reportedly, 2093 searches at 80 kHz (90×1.5 -deg beam, range 1200 m) and classifies at 350 kHz (20×0.3 -deg beam, range 300 m).

2093 is credited with twice the range and 3 times the depth performance of 193, down to the continental shelf. 2093 costs 3 times as much as the hull-mounted 193. The RN has ordered 13 units, and the first are now on trials.

Type 2093 was developed under a fixed-price contract at a total cost of £83 million, including delivery of 2 preprototypes and 10 production units.

◆ EDATS

Extra-Deep Armed Team Sweep is found in the current "River"-class steel ocean minesweepers. EDATS, deployed by paired sweepers, is a wire catenary stretched between them. Each sweeper tows a kite to depress its end of the sweep wire, and a sweep monitor pod hangs from the sweep wire just outboard of the kite, to provide an acoustic telemetry link back to the sweeper.

This system is also referred to as BAJ-Vickers Wire Sweep Mk 9 Team Sweep System; the word "armed" presumably refers to the use of explosive wire cutters rather than a serrated wire. The original EDATS used a kite to depress both the sweep wire and the kite wire. WS Mk 9 has only 1 kite, since the sweep wire is attached to the end of the kite wire, to give a deeper sweep with a given length of kite wire.

Typically, the sweep depth is 200 m and the sweep path is 350 m wide. The ends of the sweep wire are about 1000 m astern of the sweepers, and ideally the wire is towed at 8–9 kt about 2–3 m (in practice, about 10 m) above the seabed, to cut wires of mines with very short tethers. These conditions are difficult to ensure because of the current and the irregular shape of the bottom. The sweep, therefore, incorporates tension meters

measuring the pull of the wire and kites (to maintain a constant sweep speed). The pair of acoustic monitor pods are intended to maintain depth above the bottom.

The current WSME (Wire-Sweep Monitoring Equipment) can maintain the sweep 10, 20, or 35 m above the seabed by paying out or pulling in wire. BAJ is working on actively controlled depressors and diverters, which would make a single-ship deep sweep practicable. The company has completed wind-tunnel tests of a diverter with a wingspan of 2.5 m as well as a 1.6-m delta.

The first "River"-class sweepers were ordered in September 1982, after EDATS trials using the commercial stern trawlers *St. David* and *Venturer*. The British naval requirement is to sweep mines out to the edge of the continental shelf. The sweepers are steel, and in wartime they would approach from the sea to avoid influence-mine fields closer inshore.

EDATS has been ordered for the new Canadian MCDVs.

◆ Osborn (MSSA Mk 1)

Osborn is an acoustic sweep developed and manufactured by British Aerospace. In contrast to earlier broad-band noise sources, Osborn can simulate specific ship signatures and, thus, can deal with a relatively intelligent acoustic mine. Osborn combines an acoustic generator near the surface with an acoustic monitor towed at greater depth, to ensure that the required degree of signature is supplied near the mine, despite surface layering.

As of 1988, Osborn was in service in the Royal Navy and was being evaluated by the U.S. Navy.

◆ Pilotfish

This agile towed body was developed by ARE as the basis of a future deep single-ship sweep. The sweep would be positioned between 2 Pilotfish, which would control its depth. Pilotfish could also be used as a maneuverable acoustic decoy. Control is exerted by ailerons (in an X-shaped wing, for roll) and by elevators (in a cruciform tail).

◆ Scarab

This floating mine countermeasure was developed on an urgent basis by ARE, for the Persian Gulf. Scarab was intended to replace the usual technique, shooting at the mines with rifles, since some mines sank instead of exploding and thus remained dangerous. Scarab is a pair of pontoons driven by a BMW yacht engine. Guided visually to within 50 m of the mine, at a speed of about 5 kt, Scarab is then guided closer by closed-circuit television. Scarab carries a hydraulic grab. Once the mine has been secured, Scarab reverses, reeling out a cable by means of which the mine can be either towed away or detonated at a safe distance. Scarab is thus, in effect, a sea-going equivalent of the remotely controlled mine-disposal vehicles that have existed for some years.

Endurance is 10 hr at 5 kt.

Osborn. (British Aerospace)

TOWED ACOUSTIC GENERATOR

TOWED ACOUSTIC MONITOR

(Above) Osborn. (British Aerospace)

Scarab is now designated FMDS (Floating Mine-Disposal System) 1.

◆ Towtaxi

This stable actively controlled towed body was built by BAe for ARE. Maximum operating depth is 250 m (normal depth is 100 m). The body can carry payloads internally, and an external load, such as a transducer, can be slung beneath it. Presumably, Towtaxi is being used to evaluate future deep-water minehunting sonars.

◆ Invasion Sweep

During the Falklands War, AUWE designed, delivered, and shipped (via Hercules) both magnetic and acoustic influence sweeps intended to protect landing ships in the islands' inshore waters (such as Teal Inlet). The sweeps, which simulated an LSL signature, were towed ahead by smaller landing craft (LCVPs). LCVPs were considered preferable to helicopters because the craft were less easily detected from shore and, thus, did not tend to reveal the fact of a planned landing.

The magnetic assault sweep was a towed bar electromagnet in a cushioned wooden box, fed by electronics on board the towing craft. The acoustic sweep (Go-Kan) was a commercial hydrosonder (a Kango Type 637 hammer, later replaced by a Type 2500 for greater power and more output at LF) in an industrial waste-cotton bin. In fact, this sweep was used only once, for an exploratory trip on the north side of East Falkland; no amphibious craft followed on that occasion.

These improvised sweeps worked well enough to encourage postwar work on something more satisfactory. By 1983 AUWE had developed a variable-moment magnet (VMM) that could be air-shipped in a no-field condition, then set at different strengths for different conditions.

In a larger sense, the Falklands demonstrated a need for a covert sweeping capability: otherwise, the sweepers preparing the beach alert the defenders. In 1983 it was reported that AUWE was working on a torpedolike device, carrying a side-scanning sonar, for covert minehunting.

◆ AMMS

Plessey's Advanced Mirror Minehunting System employs a trainable reflector instead of a beam-preformer. The projector produces a broad beam; the reflector focuses the reflected beam. This type of system is usable for minehunting because the target, the mine, does not move and because distances are quite short: there is enough time to send and receive many narrow beams in succession. In ASW, an equivalent system would fail because a sonar waiting to receive on 1 beam before listening to the next would miss distant, fast-moving targets. In AMMS, returns from each sector scanned are stored and then displayed simultaneously.

Under Project Kingfisher, Plessey packaged several minehunting mirror sonars into hull domes for use on board U.S. frigates for mine evasion in the Persian Gulf.

The Plessey mirror minehunting sonar. The object in the foreground is the broad-beam transducer, with a narrow-beam transducer behind it, and the mirror itself in the background. (Plessey)

◆ ARMS

Plessey's Advanced Remote Minehunting System is designed to be carried by ships not intended for minehunting. A remotely operated vehicle (ROV) would swim up to 1000 m ahead of the ship and down to 300 m below it, at a speed of up to 6 kt, clearing a safe channel. The vehicle is fully stabilized, and its automatic operation can be overridden by its operator, who can make ARMS hover. The vehicle itself provides a sonar or underwater television picture on a display screen on board the operating vessel. When ARMS identifies a mine, the ROV can lower a mine-destruction charge, which is detonated from the ROV by acoustic link. There is also a cable cutter for use against moored mines.

The ROV is lowered over the side by crane, then swims out 20 m and submerges to an ordered depth and heading. The ROV is controlled via a cable tether and has a unique tandem propeller drive that should make for very accurate positioning even in high currents and turbulence. Because the ROV is positively buoyant, it will rise to the surface in the event of failure. The entire system is containerized for rapid deployment, 1 of 3 containers carrying the vehicle and its spares.

ARMS was announced in 1987, as a private venture. It may have been inspired by British fears of Argentine influence mines in the Falklands landing areas; there were no British mine-sweepers fast enough to accompany the invasion fleet, and the

ARMS vehicle hunting for mines. (Plessey)

British had no minesweeping helicopters. Plessey's claim that the 3 ARMS containers can fit a standard DC-9 would apply to the Persian Gulf problem: if ARMS had been on the shelf, it could presumably have been deployed very fast. More generally, ARMS can be seen as 1 ultimate development of the mine-hunting vehicle idea typified by the French PAP 104 or the U.S. MNS.

Total vehicle weight is about 365 kg, including a 90-kg payload (70-kg mine-disposal charge, cutters, etc.). Operating depth is 300 m. The mirror sonar detects mines beyond 600 m at 100 kHz using microsecond pulses; it switches to 300 kHz for classification.

◆ Dragonfly

The GEC Avionics/OSEL (Offshore Systems Engineering, Ltd.) modular underwater vehicle was entered in the Royal Navy's competition for an underwater remotely controlled inspection and mine-disposal vehicle (RCIV and RCMDS II). The basic vehicle (hydraulic thruster, electrical power system, control telemetry, navigation equipment, and cameras) carries a variable payload, such as a pair of manipulator arms or cutters.

The umbilical carries both power and a fiber-optic data link with 3 digital video channels (allowing for both television and sonar) and a high-speed 2-way control (and feedback) data link. Up to 6 cameras can be accommodated. There is a second fiber-optic link for redundancy, and the umbilical carries 2 additional cables so that sonar or other payload data can be carried outside the fiber-optics.

The combination of RCIV and RCMDS is to replace the single PAP 104; this combination shows much the same logic as the German choice of Pinguin A1/B3 (see West Germany above).

Two separate requirements for remotely controlled vehicles were formulated late in 1984, with an initial purchase of 20 vehicles planned (and a total of as many as 100 possible). Formal invitations to tender were issued in the summer of 1985, with bids for the inspection vehicle due by 14 November 1985 and those for the mine-disposal vehicle due by 28 November 1985.

The inspection requirement, NSR MER(S) 19/85, calls for a fast inexpensive vehicle, the RCIV, to classify a sonar contact.

The RCMDS will actually place the charges. Reportedly, both vehicles will have to be able to navigate very precisely to benefit from route surveys so that only objects not previously identified will be investigated. ECA and Honeywell offered PAP 104 Mk 5 for the RCIV, with an enhanced version for the RCMDS; Plessey/Ametek Straza offered a derivative of the Scorpio remotely operated vehicle; Ferranti offered a modified version of the existing Spring 104 designed by Robertson Tritech of Norway; Smiths Industries/OSEL offered a new vehicle; Sutec of Sweden offered a version of its Sea Eagle; Fairey offered Trail Blazer; GEC offered Microv; BAJ and MBB offered Pinguin; Marconi offered Minnow; and British Aerospace also offered a system. High-definition sonars were the subject of a parallel competition.

◆ FIMS/Manta II

Ferranti's Integrated Mine-Countermeasures System will probably equip the Canadian MCDVs. The associated Manta ROV completed Canadian trials in mid-1989, having been delivered late in 1988 to train naval reservists in mine-countermeasures techniques. The Manta II ROV is controlled by the Ferranti MC500 system (a version of the company's System 500 described in the Surveillance and Control section). Manta itself is built by SEA-Industries of British Columbia, Canada.

Manta is described as already in service (as of 1989) "with a major NATO navy." It is made of GRP, is controlled by means of a single-strand fiber-optic cable, and is fitted with 2 external mounting points. Manta can carry a side-scan sonar, a video camera, and a 250-frame still camera. Manta II will carry a high-resolution, scanning, target-classification sonar (which will retract into its belly) and will hunt ahead of the ship controlling it. The MCM version will carry a mine-disposal charge under its body.

Unlike most current ROVs, Manta depends on hydrodynamic control surfaces for rapid and precise maneuvering; it has only 2 thrusters (total 6 HP, endurance 2-4 hr on 1 battery pack). Its umbilical is paid out of the top of its tail fin.

Ferranti's FIMS vehicle, as displayed at RNEE 1989. (Author)

◆ Microv

This vehicle, developed by GEC/OSEL, is teamed with Dragonfly for the Royal Navy RCIV/RCMDS II requirement. Microv is derived from the earlier UFO and ROV oil-field support vehicles, the principal change being a low-drag frame. Power is supplied by an internal battery, and propulsion is by 3 thrusters.

Dimensions are 1 m (diameter) × 2.1 × 0.6 m; total weight is 150 kg; maximum range is 800 m; depth is 200 m; speed is 8+ kt.

◆ Minnow

The Marconi Underwater Systems, Ltd. (MUSL) mine-disposal vehicle is driven by 4 thrusters. Power is taken from an umbilical, and Minnow carries both a sonar and a television.

◆ PMS 58

This Plessey minehunting sonar is part of a larger modular family, the other members of which are described under antisubmarine warfare. PMS 58 is, in effect, a modernized Type 193 whose inboard electronics have been redesigned to take advantage of experience gained with Type 2093. As of late 1989, Plessey hoped to offer it for 30% less than other hull-mounted minehunting sonars, and for 70% less than other sonars with similar performance.

PMS 58 can be arranged for single or dual operator use; it employs identical color consoles in each case. It detects and classifies moored, surface, and near-surface mines. The sonar has a flexible architecture for alternative roles: mine avoidance sonar for sweepers or non-MCMs, standard single- or dual-operator minehunting. All versions have a special array and processing to detect and classify moored, surface, and near-surface mines. Drawings in Plessey's brochure show alternative beam patterns. The near-surface mine seems to be detected using a narrow fan beam scanning horizontally. A moored mine is detected by a similar scan repeated in vertical slices to achieve a 3D effect.

Search mode: 90-deg FoV, which can be reduced in areas of high clutter to optimize operator performance. Beams are formed for both transmission and reception. Displays: full-range PPI and B-scans, and 32-m expanded range A-scan for maximum resolution. Plessey claims that the special array configuration gives exceptional range performance against surface and near-surface mines, which is especially important for mine avoidance.

PMS 58 simultaneously searches and classifies (a minehunting equivalent of TWS). It uses both image and shadow classification; it can store up to 4 targets for recall and display. The minehunting version automatically measures target size and principal physical features; its computer compares these figures to standard preset parameters, advising the operator as to whether the target is a possible mine. The separate classification array and processor determines the height of a moored mine and can classify it at great range. The minehunting version can enhance its imagery for better classification.

Full-route survey capacity (high-definition, side-scan bottom mapping) is standard. The sonar converts slant to plan range, fully stabilized geographically; it annotates this record with range and track data.

Options:

Computer-aided detection: the sonar automatically tracks potential mine targets. It alerts the operator that targets are approaching classification range.

Multiping processing allows the alignment of sonar bearing cells on a ping-to-ping basis. Special processing enhances sonar echo points to increase recognition probability. This feature extends the range over which the sonar can detect mines with acceptably high probability.

◆ RCV225

A competitor with Dragonfly and Microv for RCIV/RCMDS II, RCV225 was developed by Honeywell Leaffield, the British contractor for PAP 104. The company developed new modules for PAP 104s on board "Hunt"- and *Sandown*-class countermeasures ships. RCV225 itself was developed for North Sea oil-field support and was first used in 1974. RCV225 is powered by 4 thrusters.

A larger RCV150 has manipulators and/or cable cutters.

◆ Sea Pup

British Aerospace Naval Division's mine-disposal vehicle was tested in October 1983.

◆ Sea Serpent

Vosper Thorneycroft's sweep was announced in 1987, to counter sophisticated mines. Two or more bodies, each containing 19 variable-moment magnets, can simulate a real ship, whose magnetic field varies along its length. The usual magnetic countermeasure, whose field is more or less uniform along its length, can be recognized as a decoy by a sophisticated signal processor. Conversely, if Sea Serpent is towed by a potential target, a sophisticated mine will detect and interpret the extended field as a magnetic sweep. The magnets are all permanent; the system requires electric power only for resetting. In effect, Sea Serpent is a huge (and sophisticated) equivalent of the U.S. Magnetic Orange Pipe (see below).

Osborn is the acoustic complement to this system.

◆ Trail Blazer

This joint-venture underwater vehicle is made by Fairey Hydraulics and ISE of Canada. Trail Blazer was designed to fit a standard 747 cargo container and can be deployed from small fishing craft. The vehicle is designed for slight positive buoyancy, using high-density foam (and more foam can be added to balance heavier loads). Propulsion is by 5 hydraulic thrusters (2 at the after end for ahead and reverse, 2 amidships for lateral movement, and 1 vertical), the electrical power for the hydraulic pump coming from the controlling vessel through the umbilical. Control is exercised through a single joystick for the 4 thrusters in the horizontal plane, with a separate control for the vertical thruster. The standard sensor is a television, and the vehicle can carry either four 50-kg (U.S. Navy standard) or one 127-kg (NATO standard) mine-disposal charge.

Dimensions are 64 cm (diameter) $\times$ 2.63 $\times$ 0.86 m; weight is 772 kg, including a 130-kg charge. Maximum range is 1+ km; diving depth is 500 m; speed is 5.75 kt.

Trail Blazer uses a 675-kHz Mesotech scanning sonar and LLLTV. It has been demonstrated during NATO breakout exercises. Trail Blazer has successfully cut moored mine cables in 120 m on the edge of the Gulf Stream (2.5-kt current) in U.S. Navy trials.

◆ Waverley 3010

This side-scan sonar is for route surveillance (100 kHz) and mine detection (300 kHz). It has been ordered by the U.S. Navy in its 3010/T version (which includes a Ferranti towfish tracker) for COOP ships (10 are on order, and there are options for 47 more). The console includes a high-resolution CRT and a thermal printer; on board the COOPs it will interface with the Integrated Shipboard Navigation System developed by the Naval Coastal Systems Center. Two Integrated Route Surveillance Systems (IRSS) based on 3010 have been delivered to the Singapore navy for COOP.

See Type 2034/2053 under ASW.

◆ DBA 4

Ferranti's CAAIS version for the "Hunt" class is the first digital minehunting-control system. It dates from the late 1970s. Capacity was originally 64 contracts, updated continuously; it has now been increased to 5000.

◆ MAINS

Racal's minehunting version of its CANE command/control system (Minehunting Action Information and Navigation System) is integrated with 9MJ400 on board Swedish *Landsort*-class minehunters. The PPI shows the current radar plot as well as the sonar search plan and current underwater contacts.

◆ MC500/SATAM

MC500 is Ferranti's minehunting version of System 500 (see the Surveillance and Control section). SATAM is MC500 adopted for the German Type 332 minehunter.

◆ NAUTIS-M

The minehunting version of the Plessey NAUTIS command/control system (see the Surveillance and Control section) is on board the *Sandown*-class single-role minehunters. A version of this system will probably be adopted for the U.S. *Avenger* class.

NAUTIS-M is a 3-console system (minehunting, operations, bridge, linked by a dual-redundant 1553 bus). As in other versions of NAUTIS, each console is modular, built up from 5 module types: a radar plot extractor, radar video module, graphics module, controller module, and power module. The display is a 16-in circular CRT (which can be provided either in analog or in raster-scan format). The keyboard and tracker ball are a separate module. The controller is the computer for CIC functions. Each console is built around an Intel Minibus, which can support 2 or more processors per bus. Each carries the full system software in its bubble memory, so the system can continue to function after a console fails. Memory is dual-ported, so each processor can work independently.

As installed on board HMS *Sandown*, NAUTIS-M is combined with paired ROV (PAP 104) control consoles, the two 1-operator NAUTIS consoles alternating with 2-operator sonar and ROV-control consoles (each with 2 operators and square CRTs). The mine warfare officer and the minehunt director each have their own NAUTIS consoles, and the sonar operators use 2 consoles for search and classification. The search operator and minehunt director have access to the ROV joystick and the ROV control display. The third NAUTIS console is on the bridge.

◆ QX3/System 880

Racal MCM's Action Information System, the third-generation, consists of a Racal Integrated Navigation System (RINS) and a Racal Action Display System (RADS). RINS suffices for mine-sweepers, which need only to know precisely which channel they have swept. RADS is required for minehunters and sweeper/hunters. A typical RADS display shows the known bottom features, the vessel's track, a safety circle around the vessel, the location of a suspected mine (with its danger circle), and the locations of other suspected mines.

In the complete system, RINS and RADS share a common central computer. The RINS inputs are various positioning systems, including the log and gyro; RINS exchanges data with the autopilot. RADS inputs are from sonar and radar; RADS exchanges data with the minehunting vehicle proper and provides data to the chart table and to tactical displays. RINS can be used to guide the helmsman, or it can control the ship automatically for great track precision.

In theory, the minehunter can make an initial route survey using a side-scanning sonar; RADS/RINS can locate any contacts precisely so that the hunter can revisit them later. The system also incorporates a track plotter, so the results of mine-sweeping or -hunting can be charted for use by other vessels. These charts also show whether coverage of an area is sufficiently complete.

QX3 can store up to 80 km of route, with 60 contacts/km. The QX3 tactical display shows a real-time ground-referenced plot, with land masses, navigational markers, underwater pipelines, and wrecks. The centerline of the task route, annotated with waypoints and the location and classification of sonar contacts, is superimposed over this background.

QX3 is in service on board British "River"-class (QX3/1) and "Ton"-class (QX3/3) minesweepers (the latter has an interface with the Type 193M sonar); it is also on board the U.S. *Avenger* class. System 880 is the export version.

UNITED STATES

◆ U.S. Towed Sweeps

There are 3 types: A, acoustic; M, magnetic; and O, Oropesa (wire sweep). All date from World War II. The principal versions are:

(i) Acoustic Sweeps

A Mk 2 parallel pipes or bars, towed broadside-on, in different versions for different frequencies and different towing speeds (4–20 kt). A Mk 2(g) was used by helicopter minesweepers in North Vietnam in 1973. Suspended from a Size 5 O-float, A Mk 2(g) weighs 130 lb and consists of 2 parallel triangular plates connected by 3 pipes, each of which is welded at each end to the vertices of the triangles. Two other pipes are pivoted from 1 of these plates; as the device moves through the water, the 2 pivoting pipes strike each other and the other pipes. Water passing between the pipes creates a venturi effect, reducing the pressure between them and thus causing them to collide. The faster the tow, the greater the intensity of the collisions.

A Mk 4 (TB-25) towed hammer box, conceived for small craft in restricted areas but later extended to all types. A Mk 4 consists of a hydraulically driven hammer in a streamlined box, driven by a gasoline engine on board the sweeper. A Mk 4(v) weighs about 1300 lb. Dimensions are 40 × 70 in. Output is 60–600 Hz. TB-27 (part of SLQ-37) is Towed Body 4(V). Dimen-

A U.S. acoustic sweep, photographed in 1987. It resembles, but is not identical to, the old A Mk 2. It is streamed suspended from an O-type float. (U.S. Navy)

A Mk 4(v) acoustic sweep. (U.S. Navy)

sions are 40 in (dia) $\times$ 70 in (1300 lb). It produces pulsed (duty cycle 0–100%) HF noise (40–600 Hz).

A Mk 6 VLF acoustic sweep, the towed eccentric mechanism, usually towed about 1200 yd astern of a coastal sweeper. A Mk 6(b) uses a diaphragm driven by pistons connected to an eccentric driven by an electric motor. Weight is about 3500 lb. During Operation End Sweep, the clearance of North Vietnamese waters, A Mk 2(g) was recommended as a replacement for the A Mk 6(b) then in use by the surface sweepers. A Mk 6(B) Mod 5 is TB-24 (used in SLQ-37); it is a motor-driven mechanical oscillator made by the John Bean Food Machinery & Chemical Co. Dimensions are 37.75 in (dia) $\times$ 69 in, and weight is 3500 lb. It operates at 10–35 or 10–22 Hz. TB-26 is Towed Body 6(B), also part of SLQ-37. Dimensions are 23 in wide $\times$ 45 in high $\times$ 65 in long (2800 lb). It produces pulsed (20–100% duty cycle) LF signals at 6–40 Hz.

There was also an explosive sweep (A Mk 5).

(ii) Magnetic Sweeps

M Mk 1 magnetized iron rail, which could be extemporized. It was not standard after World War II, but a device of this type was used in Vietnam (in the Cua Viet River, after magnetic/acoustic mines were found there). The MOP (see below) is reminiscent of this device.

M Mk 4(m) small 2-ship closed loop.

M Mk 4(i) 2-ship single-catenary small-craft sweep, using special tails, the short legs of which are connected by an insulated cable forming the catenary; the long legs stream aft.

M Mk 4(v) postwar variation on M Mk 4.

M Mk 5(c) standard large-sweeper sweep, consisting of 2 legs (buoyant conducting cables) married together through the 675-ft length of the shorter leg, with the longer leg streaming aft another 900 ft. In some arrangements 2 or more ships could sweep together, pulsing their tails synchronously.

M Mk 5(a) straight-tail electrode sweep (I-sweep).

M Mk 6(a) J-sweep: the long leg curves around to meet a diverted line towed by the ship and connected to an Oropesa and a kite.

M Mk 6(b) single-ship closed-loop sweep, using Oropesa floats to keep the legs apart.

M Mk 6(h) closed-loop sweep, the 2 legs meeting at a diverter line streamed from an Oropesa.

(iii) Oropesa (Wire) Sweeps

O Size 1 largest, for ocean sweepers (MSO and MCM). When streamed with 300-fathom wires, the swept path is 500 yd wide (double sweep) at maximum sweep speed, about 8.5 kt for an MSO. A single-side sweep can clear a 250-yd path at 10 kt. Sweep depth is 5–35 fathoms (maximum 40 fathoms).

O Size 4 modified, for coastal sweepers (MSC). With 300 fathoms of wire streamed on each side, the swept path is 420 yd at 8 kt; wire depth is 2–30 fathoms.

O Size 5 small, for minesweeping launches (MSL), etc. This type uses explosive cutters because the craft are too slow for the saw action of the wire to cut mine moorings. Sweep speed can be up to 7 kt. With 250 fathoms of wire streamed on 1 side, the swept path is 176 yd wide. This sweep could be used as an emergency or shallow-depth sweep, with a wire depth of 2 or 3 fathoms. Size 5-G is used for adapted landing craft, etc., and was modified for helicopters and MSBs. 5-G uses a different otter and depressor and can be streamed at relatively high speed in shallow water, e.g., for assault purposes. Depth control is more precise than in Size 5, so 5-G can operate in 1–7 fathoms, at 6–14 kt. With 150 fathoms of wire streamed on 1 side, the swept path is 70 yd wide.

S Type C a 2-speed high-speed sweep for converted destroyers, but such ships no longer exist. The 2-speed feature referred to the ability of the special paravanes to stabilize the sweep in 2 quite different speed ranges, around 12 and 20 kt.

All the standard sweeps are designed to deal with mines floating close to the surface. When the sweeps were designed, the only exceptions were ground mines (which cannot be wire-swept) and antenna mines, the cases of which might be well below the surface. However, the sweep wire could brush the vertical antenna, causing the antenna mine to explode. At present the United States, like her allies, is developing a deep sweep to cut loose the cases of rising mines, which may be over a thousand feet below the surface.

◆ ALQ-141/SLQ-35

ALQ-141 is called DOUBLE ALFA; SLQ-35, a ship-towed version, is ALFA TWO. The designation suggests an acoustic sweep, presumably covering a different portion of the spectrum than ALQ-160. ALQ-141 was described about 1979 as an electronic counter to deep-water rising mines. This sweep is manufactured by Westinghouse. There was also an EDO ALQ-138, probably an unsuccessful competitor.

A helicopter-towed acoustic countermeasure used during the clearance of the Red Sea in 1984. Although labeled Mk 104, it is far more sophisticated than the simple bars used in Vietnam and is presumably ALQ-141 or -160. (U.S. Navy)

◆ ALQ-160

ALQ-160 is a helicopter-towed acoustic sweep using a stable towed body.

◆ ALQ-166

EDO's magnetic minesweeping hydrofoil sled is the successor to Mk 105. ALQ-106 exploits the greater pulling capacity of the new MH-53E helicopter, which replaces the original RH-53D. Unlike the earlier catamaran, ALQ-166 is a monohull and, thus, can carry a heavier load in the same dimensions. The new 1200-HP Avco Lycoming engine is about 3 times as powerful as the engine of the Mk 105, to drive a more powerful sweep generator. Reportedly, 166 quadruples the net sweep rate of the earlier device and can operate at 6–30 kt. A sled-mounted ASQ-182 measures the magnetic environment so that sweep track spacing can be optimized. The second production ALQ-166 was delivered in FY83. EDO began the development of this Light-weight Magnetic Sweep (LMS) with internal R&D funds, to counter the next-generation mine threat; this LMS was then

ALQ-166 (EDO)

successful against existing advanced projects in a navy trade-off study.

TF-40 engines were installed in an ALQ-166 in FY88, and operational evaluation began in FY89.

Reportedly, it is possible to use a magnetic sweep of this type in conjunction with a water-pressure monitor, so that pressure/magnetic mines can be swept at the turn of the tide. Such mines avoid detonation at the turn of the tide by seeking an accompanying magnetic signature. Similarly, it would be possible to sweep pressure-acoustic mines using a pressure monitor and an acoustic sweep. However, at least some pressure mines avoid this problem by monitoring the rate of pressure change, which is much faster for a ship than for the tide.

◆ AQS-14

AQS-14 is Westinghouse's high-speed helicopter-towed minehunting sonar. It is actively controlled for platform stability; the stabilized towed body carries a high-resolution side-scanning sonar. AQS-14 is said to allow sweeping at a rate about 40% faster than can be achieved by conventional methods.

The sonar is a Westinghouse-patented multibeam all-range focusing type, providing an operator with a continuous high-resolution television image of objects to either side. The system employs active controls to keep itself clear of both the bottom and the surface and can even right itself if launched upside

AQS-14 helicopter-towed fish, with the towing helicopter in the background. (U.S. Naval Institute)

down. Objects detected by the sonar are marked by the towing helicopter for further investigation.

Westinghouse describes AQS-14 as suitable for installation on board hovercraft and other surface-effect ships.

Production was approved in March 1980, operational evaluation having been completed in September 1979 (and having proceeded since FY76). As of March 1988, 29 units had been made. This sonar operates with ALQ-141. AQS-14 was first used operationally during the Red Sea operation in 1984, marking minelike objects with sonar beacons for subsequent inspection either by remotely operated vehicles or by divers.

◆ AQS-17(V)

This experimental, helicopter, minehunting sonar was developed by Allied-Signal (Bendix Oceanics). Although not adopted, it is interesting as an example of current technology. The 200-kHz sonar operates in search and classification modes, over 90- and 60-deg sectors; it is trainable at 10 deg/sec. In each case, it produces 128 narrow beams, 18×0.90 deg for search and 18×0.45 deg for classification. Beams are formed electronically and processed digitally. The beams can be trained between $+10/-45$ deg. Maximum search range is 600 m; classification range is 300 m. The 25-cm [10-in] CRT operates in PPI format, with 150-, 300-, and 600-m range scales and a 30-m expanded classification display. There are 16 shades of gray (presumably the CRT is digital). The towed body is 100 (dia) $\times$ 230 cm (320 kg in air). Maximum operational depth is 100 m.

Allied-Signal offered this sonar in shipboard as well as airborne form.

AQS-17 was conceived as part of a system employing mine-killing miniature torpedoes. Although AQS-17 itself has been abandoned (probably in favor of AQS-20), the expendable-mine-destroyer (EMD) concept survives (see below). Compared to AQS-14, AQS-17 provided mine classification as well as search.

◆ AQS-20

AQS-20 is a sonar mine detector, formerly the Advanced Minehunting Reconnaissance System. Fabrication of the engineering development model is to begin during FY91 (having slipped a year because of a reduction in FY88/89 funds). An associated mine neutralizer also slipped a year.

◆ Mk 24 Underwater Ordnance Locator/Klein 595

This lightweight side-scanning sonar for minehunting and channel conditioning was developed by Klein Hydroscan. Earlier UOLs were magnetic detectors. Mk 24 can be used on board virtually unmodified commercial helicopters and small craft, and it has been adopted for the U.S. Craft of Opportunity Program. Mk 24 has also been adopted for the 7 surviving U.S. minesweeping boats (MSBs), 4 of which were sent to clear the Persian Gulf in 1987. Mk 24 was used during the clearance of the Suez Canal after the 1973 Mid-East War and has been used extensively since then by U.S. Navy explosive-ordnance-disposal teams and similar organizations. Foreign naval users include Sweden, Greece, Colombia, South Korea, New Zealand, Norway, Pakistan, Portugal, West Germany, the Netherlands, Indonesia, Thailand, and Canada.

Small size and light weight are achieved by using VHF: Mk 24 operates at 100 kHz (beamwidth $\frac{3}{4}$ deg), but Klein offers an optional very high resolution 500-kHz sonar. In the past, this sort of frequency has generally been associated with very short range, perhaps a swath width of 100 m. However, Klein claims a swath width twice that. There is also an optional 50-kHz fish for large-area sonar sweeps, e.g., for channel surveys. It covers a 1.2-km-wide swath. An optional 3.5-kHz sub-bottom profiler can indicate bottom hardness and, thus, can indicate whether buried mines are likely to be a problem.

Total weight, for both recorder and fish, is about 150 lb, and range is selectable in 13 increments between 25 and 600 m. The fish can be operated down to 2300 m or, as an option, 12,000 m.

The Klein 595 100/500-kHz system was supplied in 1988 to

Klein 500-kHz (extended-range) side-scan sonar records a Mk 18 base with a Mk 17 moored mine (both British types) moored about 6 ft above the bottom, and a simulated Destructor (Mk 82 bomb with mine fuze) bottom mine at the bottom. The fish was towed at 2.5 kt, and water depth was 22 m. (Klein)

the Royal Australian Navy for its COOP program. In 1984 the Royal Swedish Navy bought 7 Klein side-scan sonars, with a reported range of about 900 m (which seems too great) for in-shore ASW.

◆ Shadowgraph (C. Mk 1)

This side-looking mine-detection sonar was built by Gould; the designation refers to a sweep to deal with combination (as opposed to acoustic or magnetic) mines. Shadowgraph was originally designed during the 1960s for U.S. minehunters operating in shallow water, but the system did not become operational. However, over 100 units were manufactured for the U.S. and French navies. Stored U.S. units were proposed as COOP sensors, but the Klein Mk 24 was adopted instead because of its lower cost (modification of Shadowgraphs would have cost more than new Kleins) and greater capability and reliability. Shadowgraph's fish was very heavy, so it would be awkward to handle from small COOP craft.

Total weight (recorder and fish) is about 1500 lb, and range is fixed at 82 ft. Frequency is 1.4 MHz to port, 1.3 MHz to starboard. Operating depth is 3–30 fathoms. The towed fish, which maintains itself at a preset height above the seafloor, carries 2 markers that it can drop.

Shadowgraph provided so detailed a picture of the bottom that, in theory, it could be relied upon to classify the objects it saw. It was then practical to use guided weapons to destroy mines, since the rate of false alarms would (in theory) be relatively low. The destruction vehicle was Sea Nettle, a wire-guided torpedo carrying 75 lb of HBX. Shadowgraph was successfully evaluated in 1962–63, and it and Sea Nettle were included in the new minesweeper designed in 1965–66, but the project died because of the demands of the Vietnam War.

C. Mk 1 was displayed publicly for the first time in 1980, when Gould was hoping to find new customers for a solid-state version. The French DUBM-41 is derived from Shadowgraph.

◆ PQS-1/SQS-37

PQS-1 is a hand-held mine-clearance sonar for divers. It uses continuous FM transmission or passive detection of a sonar beacon. PQS-1 employs a 12-in conical reflector, which forms a 9-deg beam at 70 kHz. In search mode, frequency is swept over 30 kHz (between 50 and 90 kHz); there are 3 range scales (20, 60, and 120 yd). Source level is 72 dB. The reflected beam is combined with a sample of the transmitted beam to form a difference frequency in the audio range; the minimum and maximum frequencies in this range correspond to the minimum and maximum ranges of the range scale selected. The lower the tone, the closer the object. The set can also be used to detect 40-kHz marker beacons; the sonar indicates direction but not range.

SQS-37 was PQS-1B modified for riverine use in Vietnam. SQS-37 could easily be transferred from craft to craft. This sonar was also used for helicopter-minehunting trials in the mid-1960s. A towed body (Turtle) carried a modified PQS-1 for detection, a television for classification, and a destruction charge. The system was rejected because water was often too turbid for the television.

PQS-1B in use. (U.S. Naval Institute)

◆ PQS-2A

This nonmagnetic portable sonar was announced in 1986 by General Instruments Corp. Modes are active (continuous transmission) and passive (beacon reception, in the 24–45-kHz range). Active range scales are 20, 60, and 120 yd; like PQS-1, this sonar uses an FM slide, so the tone of the echo indicates the range. Beamwidth is 6 deg, and a 12-in object can be detected at 120 yd. In the passive mode, a 39-kHz beacon can be detected at up to 2000 yd. The sonar can operate down to 300 ft. Dimensions are 4.5 × 12.5 in (height, with handle, 9 in); total weight is 8 lb.

◆ SLQ-35

See ALQ-141 above.

◆ SLQ-37

This modular magnetic/acoustic combined sweep is found in the new U.S. *Avenger* class. Three were procured under the U.S. FY89 budget.

◆ SLQ-48

See Mine Neutralization System, below.

◆ SQQ-14/P2072

The standard U.S. minesweeper/minehunter sonar of the 1960s is also built under license in Italy in a modified version. SQQ-14 equips many minesweepers transferred by the United States to foreign navies. In a license-built form (P2072), SQQ-14 equips Italian *Lerici*-class minehunters. SQQ-14 is basically UQS-1 fitted with CXRP, a copy of the British Type 193 high-resolution sonar, for classification.

SQQ-14 is unusual among VDSs in that it is carried on a rigid retractable boom rather than at 1 end of a flexible cable. The reason seems to have been an inherent instability in variable-depth bodies, which tend to swing back and forth at speeds above 5 kt, ruining the accuracy of their narrow beams. In later systems, such as SQQ-30 and the British Type 2093, considerable attention has, therefore, gone into stabilizing the variable-depth body using fins.

SQQ-14 was standardized in 1960. The data that follow are for the Italian-built P2072 version; they are probably also accurate for the U.S. SQQ-14. Maximum depth is 45 m beneath the keel. SQQ-14 consists of an 80-kHz search sonar (which is also used for route surveys) and a 350-kHz classification sonar. The search sonar has a 1.5-deg-wide beam (100-deg FOV); azimuth resolution is 1.5 deg, and range resolution is 1 m (1.0-msec pulses, 15 kW, 126-dB source level). The classification sonar has a 0.3-deg beam (18-deg FOV); azimuth and range resolutions are 0.3 deg and 8 cm, respectively (0.1-msec pulses, 15 kW, 125-dB source level). In search mode the sonar scans a sector at least 82 deg wide at a speed of at least 15 deg/sec. Once a target has been detected, it is transferred to the classification sonar. Both the search and classification sonars can be tilted between +10 and -30 deg (elevation). There is also a side-scan mode.

The FIAR version has been completely redesigned for the Italian *Lerici*s. Only the mechanical hoist has been retained; the transmitter electronics have been relocated into the towed body, and there are new consoles.

SQQ-14 users are Belgium (6 *Dash* class), Italy (SQQ-14/IT in 6 new *Lericis*, SQQ-14A in 4 original *Lericis*, 7 converted *Adjutant* class), Saudi Arabia (4 MSC 322 class), Spain (4 *Aggressive* class), and the United States (2 *Acme* class, 19 *Aggressive* class).

◆ SQQ-30

Replacement for SQQ-14, SQQ-30 is a much modified solid-state version of the earlier sonar. Unlike the earlier sonar, SQQ-30 is towed by a conventional cable/umbilical rather than articulated links. It can, therefore, operate at greater depths and can be handled more easily. The towed body is self-stabilizing and reportedly houses 3 sonars. SQQ-30 searches at 80 kHz (90 × 1.5-deg beam, range 600 m) and classifies at 350 kHz (20 × 0.3-deg beam, range 200 m).

SQQ-30 will equip the new generation of U.S. mine-countermeasures vessels until SQQ-32 becomes available.

◆ SQQ-32

Raytheon/Thomson Sintra's minehunting sonar is for later U.S. MCM- and MHC-type countermeasures ships. SQQ-32 was originally designated AMSS (Advanced Minehunting Sonar System). This sonar uses DUBM-21 and TSM 2022 technology for its high-resolution classification sonar, and Raytheon technology for its search component.

SQQ-32 displays search and classification data simultaneously, using separate search and classification transducers in a stable variable-depth towed body. There are 2 identical display consoles, each of which can display either set of data. Although SQQ-32 normally uses 2 operators, it can be located in 1 mode by only 1. The search display shows the location of objects of potential interest; the classification display provides images, either of the object itself or of its sonar shadow. Both methods are complementary: the echo mode is most useful for objects clear of the bottom (and for rejecting objects clearly not mines

SQQ-32 towed body, showing the separate detection (belt of transducers) and classification (bar transducer at bottom) arrays. (Raytheon)

by their apparent shape); the shadow mode, for objects on the bottom (where reverberation is a major problem). A computer is used to help classify the objects detected, so as to reduce the operator's workload. Multibeam operation increases the sonar's search rate. SQQ-32 searches at 35 kHz (60 × 3.1-deg beam) and classifies at 445–650 kHz (14 × 0.13-deg beam).

SQQ-32 can also be used from the hull in shallow water.

The *Osprey* will be fitted with 1 of the refurbished test sets. Operational SQQ-32s will be delivered from mid-1991 on, the first on board the *Warrior* (MCM 10). The first export sale, to Japan, was approved in the fall of 1989.

◆ SQQ-35

Dowty (Waverley) Type 3010T (British Type 2034/2053) side-scan sonar for craft-of-opportunity, a designation assigned in 1990.

◆ UQS-1

This minehunting sonar of the 1950s remains in service on board most ex-U.S. minesweepers. UQS-1 is a short-pulse, electronically scanned sonar. UQS-1 has been superseded in the U.S. Navy by SQQ-14. UQS-1D has a total weight of 2126 kg and a frequency of 100 kHz (10-kW pulses). Range scales are 200, 500, and 1000 yd; precision is 5 yd at 200, 25 yd at 500, and 50 yd at 1000. Resolution is 2 deg in azimuth and 10 deg in elevation (2 m in range). The beam is 20 × 10 (vertical) deg; but it rotates, and it can scan up and down to cover angles between +5 and -50 deg. Bearing precision is 30 min. The sonar can scan over a 90-deg sector or over all 360 deg, or it can be trained manually. UQS-1 is not stabilized, and it cannot provide the mine image required for classification.

UQS-1 was derived from the World War II Underwater Object Locator Mk 4 (most UOLs were magnetic); about 150 UQS-1s were built in 1951–54. SQS-15 was a variable-depth version. SQQ-14 was derived from this sonar.

UQS-1 users are Belgium (4 *Adjutant* class), Denmark (3 *Adjutant* class), Greece (9 *Falcon* class, 5 *Adjutant* class), Iran (1 *Falcon*), Italy (9 *Adjutant* class, 4 *Agile* class), Korea (probably 5 MSC-289 class, 3 MSC 268 class), Norway (7 *Falcon* class), Spain (8 *Adjutant* class), Taiwan (13 *Adjutant* class), Thailand (4 MSC 289 class), and Turkey (12 *Adjutant* class, probably 5 ex-Canadian Bay class and 1 ex-U.S. Cape class).

◆ Airborne Mine-countermeasures System Mk 103 and A/N37U

This helicopter-towed moored-mine sweeping system is manufactured by Boeing Vertol. Mk 103 consists of a tow wire, sweep wires (with explosive cutters), floats, a depressor, otters, and float pendants. In operation, the helicopter sits at the extreme end of the flight deck, streams the gear into the water, and then takes off. Total weight is 1178 lb.

The earlier Mk 101 was a mechanical sweep (1964). Mk 102 was a contemporary high-speed mechanical sweep (VERMOOR-AMCM), which could be towed by a helicopter in an assault at a 12–25-ft depth at up to 25 kt, or at a 25–60-ft depth at a slow speed to sweep a path at least 300 ft wide. Maximum drag was 5500 lb regardless of load, and the sweep could be used to port or starboard or as a double sweep. It used one lead float, one depressor, and 2 otter markers; total weight was 3050 lb, not including the tow cable and cutters.

The main recent development is A/N37U, a controlled-depth, rapidly deployable sweep for use at greater depths. This deep sweep is now being adapted to surface ships as the single-ship deep sweep (modular). Four engineering-development models were scheduled for procurement in FY88. As of early 1989, limited production was scheduled to begin in FY90, with technical and operational evaluation in FY91.

◆ Airborne Mine-countermeasures System Mk 104

This helicopter-towed acoustic-mine countermeasure consists of a cavitating disk within a venturi tube, driven by a water turbine. Mk 104 was originally developed by American General. For this system the helicopter supplies sweep power. Minimum sweep water depth is 30 ft, compared to 15 ft for an MSL or MSB and 30 ft for an MSO or MSC. Total weight is 180 lb. Dimensions of the towed body are 26 in wide × 35 in high × 49 in long (87 lb).

Mk 104 and the other major helicopter-towed mine countermeasures were bought in quantity in response to Project SIXTY Decision 5 (1970, under Admiral Zumwalt), which ordered the mine-countermeasures forces reorganized to emphasize helicopters. In 1971 the navy borrowed 15 Marine Corps CH-53A helicopters to equip the first squadron, HM-12. This squadron swept North Vietnamese waters in 1972–73 and the Suez Canal in 1974–75.

◆ Airborne Mine-countermeasures System Mk 105

Mk 105 is the EDO helicopter-towed minesweeping hydrofoil sled. It carries a power pack (gas-turbine generator) for magnetic sweeping. Mk 105 is being succeeded by ALQ-166. Mk 105 was approved for service use in 1970. The first production models were delivered on 1 July 1972. Mk 105 was first used operationally during the Hanoi-Haiphong sweep at the end of the Vietnam War and was also used for the Suez Canal sweep the following year. Initially the sweep had to be streamed from the helicopter-carrying ship (e.g., an LPH); the sweep was then attached to the sled after having been streamed, and only then did the helicopter lift the sled into the water. The helicopter pilot had to thread the tow ball through the throat of the lifting device of the sled, a very difficult operation. It was discovered during training that the sled could be launched much more safely from the well deck of an LPD. The sled (with its foils up) was positioned at the after end of the well deck, ready for streaming, with the ship ballasted so that the ramp was about 18 in above water. The helicopter then picked up the tow cable from a small landing craft (LCVP) and carefully pulled the sled down the ramp.

The sled is typically towed at 25 kt, about 450 ft behind the helicopter, the on-board gas turbine powering twin magnetic tails. The sled becomes foilborne at 13 kt, and minimum sweep water depth is 12 ft. The sled trails a conventional open-electrode magnetic sweep 600 ft long. The total weight is 5200 lb.

Mk 105 sled. (EDO)

Six Mk 105 sleds were purchased by the Shah of Iran, and reportedly they were delivered before his fall.

See also EDO Model 819 (MIMS), below.

◆ Airborne Mine-countermeasures System Mk 106

Mk 106 is a combined Mk 104 and Mk 105 for acoustic/magnetic sweeping, the Mk 104 being attached to 1 of the Mk 105 tails. This device was used extensively during the 1984 Red Sea sweep.

◆ Buried-Mine Hunting System

This system is an FY88 new start, in collaboration with Britain and Germany. It is to use both magnetic and acoustic sensors. The ASQ-81 MAD (on a catamaran) was used to locate buried mines at the end of the Vietnam War, in Operation End Sweep.

◆ Mine Neutralization System (SLQ-48)

SLQ-48 is the current U.S. unmanned minehunting submersible, equivalent in principle to the French PAP 104. The vehicle takes its power from the launching ship, proceeding at a speed of 6 kt. Weight in air is 2500 lb; the vehicle has 20 lb of positive buoyancy and rises to the surface in the event of failure. Dimensions are 12.5 × 3 ft, and power is provided by two 12-HP electric motors. There are also 2 side thrusters. The umbilical cable is 3500 ft long. Including its shipboard components, the mine neutralization system weighs 26,000 lb and requires a 60-kW power source. Honeywell, the manufacturer, claims that MTBF is 120 hr, with a 4-hr MTTR.

The vehicle itself carries a small high-definition sonar and an acoustic transponder that enables the vehicle to be tracked by the shipboard minehunting sonar. There is also an LLLTV for examining a mine or minelike object. The vehicle carries MP-1 (Mk 26-0) cable cutters and an explosive mine-destruction charge (MP-2, Mk 57-0).

Prototypes were tested in 1971–77, with a decision to begin engineering development made in 1977. In 1978 Honeywell was awarded a contract for 2 prototypes, and operational evaluation of the engineering-development model was completed in September 1982. It was tested on board the *Fidelity*.

The Honeywell Mine Neutralization System vehicle. (Honeywell)

It was announced in 1985 that the mine neutralization system would be supplemented by an advanced remotely operated underwater vehicle (ARDROV) that will help locate and identify objects, perhaps like the projected German Penguin A3.

◆ Special Acoustic Sweeps

Several special noisemakers were manufactured by the Naval Coastal Systems Laboratory (Panama City) specifically for shallow-water mine clearance as part of Operation End Sweep (1973). They had to be simple and were turned over to the North Vietnamese. Although these noisemakers probably would not be precisely duplicated in future, they are interesting examples of extemporized devices:

Drum Sweep a device to sweep magnetic-acoustic mines (DST Mod 4) in canals and rivers too narrow for helicopters or boats. Drum Sweep was a cut-down 55-gallon drum with a 3-HP lawnmower engine inside, and with permanent magnets and a small paddle wheel outside. The paddle rotated the drum about its vertical axis. This rotation changed the drum's magnetic field and helped free the drum from snags so that it could ride the current down river. The drum's acoustic signature was provided by the engine and by the exhaust, which was vented into the water. Five drums were provided to the North Vietnamese.

Rotating Acoustic Pipe (RAP) a 4-ft section of 10-in steel pipe with a towing swivel, nose cone, and external vanes causing RAP to tumble when towed. Scrap iron bars inside tumbled to produce noise. When towed with an MOP (see below), the RAP could detonate a U.S. seismic/magnetic destructor (DST Mod 4, at its most sensitive setting). Twenty were manufactured for the North Vietnamese.

Big Noisy Orange Barrel (BNOB) a towed barrel noisemaker developed in part by the mine force in Vietnamese waters. BNOB was a 55-gallon drum containing scrap iron and fitted with vanes on its outside; it worked much like the RAP. One was built.

Magnetic Orange Barrel (MOB) a horizontal coil of about 400 ampere turns, 7 ft in diameter, with a battery at its center to supply current. MOB was towed on a styrofoam float by a boat. This device was experimental only.

Sophisticated Orange Barrel (SOB) (acoustic solenoid barrel) a solenoid inside a 55-gallon drum, energized by a battery inside. As the solenoid was pulsed, it struck the inside of the barrel. The SOB designation differentiated it from BNOB; SOB was not built.

Static Loops static coils used for inland sweeping. Dropped on the bottom or placed on a raft (or suspended from floats), these coils could be pulsed to simulate the signature of a passing boat;

they were repositioned after sweeping. Power could be provided either by a battery or by a welding generator. Two such loops were lent to the North Vietnamese.

There was also a drone minesweeping boat developed specifically for End Sweep (and not, therefore, identical to the drone sweepers developed during the Vietnam War). This boat was commercial fiberglass (14 ft 6 in × 5 ft) and could tow RAP, MOP, and the A Mk 2(g) sweep. One problem was that the existing drone sweepers (MSD) had magnetic signatures that would have detonated destructors under them. Ten remotely controlled boats, which could be operated from a range of 2 miles, were provided to the North Vietnamese.

◆ SPU-1/W (MOP)

SPU-1/W is a magnetized pipe filled with styrofoam; MOP means Magnetized Orange Pipe. It was employed during the sweep of Haiphong harbor at the end of the Vietnam War. At that time, it turned out that some of the mines laid in Vietnamese waters were so sensitive that they would have destroyed the sweep sleds. A precursor sweep was needed: the MOP. This procedure was interpreted by some as demonstrating shortcomings in helicopter sweeping, but in fact precursor sweeping was more a commentary on the design of mines sensitive enough to destroy small wooden craft held together by metal fasteners. The MOP was also needed to sweep water too shallow for a Mk 105.

A modern version of the 1940 iron-rail sweep (M Mk 1(m)), MOP was a pipe long enough to provide the magnetic mass of the rail and wide enough to be buoyant (30 ft × 10 in diameter). MOP was sealed at each end, filled with styrofoam, fitted with towing lugs, and magnetized. A helicopter could tow as many as 3 MOPs in tandem. A total of 150 were manufactured by the Naval Coastal Systems Laboratory (Panama City).

In 1972, when Operation End Sweep was being planned, there was some fear that not enough Mk 105 sleds would be available in time. One proposed solution was to wrap a MOP in coils energized by a generator in the helicopter, increasing the sweep path's width by a factor of 5.

◆ ALARMS

Northrop's Airborne Laser Radar Mine Sensor employs a downward-looking blue-green laser pulsed at 10 kHz. Prompted by reports of moored mines in the Persian Gulf, Northrop proposed the system to DARPA in the summer of 1987 and was awarded a development contract late in November 1987. The first tests were run early in August 1988, at San Clemente Island. Northrop claimed that these tests showed a search rate at least 10 times the current visual rate.

ALARMS used a blue-green pulsed copper-vapor laser (510 nm, near the blue end of the spectrum) for good water penetration, scanning in a 682-shot oval pattern (circular with respect to the helicopter). The pattern hits the mine with both its forward and trailing edges; backscatter indicates shape and position in 3D. Trials showed that the shadow cast on the seabed by the laser provided the most informative data. Mines are displayed as squares, the color of the square showing the depth. The system shows only moored mines; it is range-gated to reject the reflections of the surface and the bottom. Gain is adjusted for sea-state.

The Northrop system is built around a Larson 500 ladar (laser radar) built by Optech Systems of Downsview, Ontario, Canada. Reports of operating depth vary. DARPA required 100 ft, but it was also reported that the system could reach down to 300–600 ft.

ALARMS was never actually deployed to the Persian Gulf. It is still a developmental system, housed in a 35-ft container and carried by a big MH-53 helicopter. Northrop is seeking funds for a more compact version. ALARMS has not received any funding since FY88; it is included here because it is probably typical of an important class of minehunting laser systems. As tested late in the fall of 1988, it was beaten out by the Kaman

Magic Lantern: it achieved only about half the depth of the Kaman system and showed poor resolution.

ALARMS is not the only laser minehunting system proposed; see also the description of the Australian laser system in the ASW section. See Magic Lantern, below.

◆ AMDAS

The Marine Corps's Airborne Mine Detector and Survey system is intended to find mines 6 in in diameter in surf and turbid water. The concept was successfully tested in FY89. This device would be carried on board a UAV, its data transmitted back to commanders via a new Airborne Imagery Transmission (AIT) data link. In December 1990 an exhibit prepared by the Naval Coastal Systems Center, the system sponsor, showed how AMDAS works. The laser scans about 500 ft on either side of an airplane or helicopter to a depth of 10 ft in surf or muddy water. Search rate is 16–80 nm²/hr. The system produces a 50 × 50-pixel image per cell. It is expected to transition to development in FY91.

Late in October 1990 Senate and House appropriations committees recommended that DoD choose between AMDAS and the Navy Magic Lantern because both systems use the same basic technologies.

◆ CLG

Closed-loop degaussing, under development to meet an OR issued 19 December 1985. Strictly speaking, this is a means of protecting mine-countermeasures craft rather than a direct mine countermeasure. Here closed-loop means self-correcting: the ship's degaussing circuits are controlled by sensors outside the hull, which measure the actual magnetic field. The better the degaussing, the more easily the sweeper or hunter can operate near magnetic mines.

◆ Commercial ROVs

Commercial ROVs were ordered in December 1987 for use on board ocean minesweepers (MSOs), to identify mines. Deliveries began in the fall of 1989. Several are described below.

◆ EMD

Expendable Mine Destructor, a mine-killing miniature torpedo, was originally conceived to work in tandem with the AQS-17 helicopter minehunting sonar. EMD is preprogrammed by its operator's observing it on sonar, and the operator can override the program (i.e., provide mid-course guidance) via an acoustic link (range 800 m). There are 32 commands. EMD has its own high-definition HF sonar array, and it can operate independently, homing on a bottom transponder. Acoustic homing range (for final kill) is typically 30 m. The sonar guides EMD over the target mine at a height of 0.5–1 m, and the weapon fires its 4 shaped-charge downward-looking warheads. The manufacturer, Allied-Signal (Bendix Oceanics), claims that it is effective even against a buried mine. The company claims probability of a hard kill (detonation of mine explosive) is 0.90; that of a soft or hard kill (at least disablement of the mine trigger)

The EMD concept, according to Bendix (drawing displayed at RNEE 1989). (Author)

A model EMD displayed at RNEE 1989, showing its 4 downward-looking shaped charges. (Author)

is 0.95. Propulsion is by a lithium or thermal battery (maximum speed 12 kt, endurance 15 min, i.e., 4000 yd at 8 kt). EMD can operate in currents of up to 5 kt. Maximum operational depth is 300 m [1000 ft]. Dimensions: 20 × 100 cm [8 × 39 in]; weight, including warheads, is 25 kg [55 lb].

EMD has been under development since 1986, Royal Ordnance (of Britain) being responsible for the warhead. As of 1989, estimated unit cost was \$12,000.

◆ Magic Lantern/DEMON

In September 1989 it was reported that, at strong congressional urging, the navy was about to begin a crash program to deploy a laser mine detector on all LAMPS helicopters. It is a blue-green laser, reportedly effective down to 200 ft, and its success has inspired interest in ASW applications. In 1989 it appeared that with adequate funding Magic Lantern could be deployed by 1991.

Magic Lantern is a mine-detection LIDAR (laser radar) that images underwater objects. All of the other surface-piercing LIDARS use a very small spot and require computer processing (which cannot be done in real time) to reconstitute an image. Magic Lantern produces a spot of light, range-gates it to remove surface reflection, and puts the remaining light through a television camera to produce a direct image. In the future it will be possible to combine several such images to achieve a greater search width (range gating limits the width per image because a greater width corresponds to a greater variety of slant ranges to the water surface).

Magic Lantern began in the fall of 1987 as a Kaman private venture. It received some U.S. Navy funding under Project Kingfisher (see below) and underwent a very successful 6-week demonstration. More funds were provided for further scientific work, which was completed in May 1990. A second system was assembled for a helicopter. As of early 1991, Congress wanted Magic Lantern in all MH-53E mine-countermeasures helicopters for rapid mine search during exploratory sweeps and minehunting. The naval reserves wanted it in their helicopters and had adopted this requirement as an official position.

DEMON is another navy laser detection program (no other details are available).

◆ Magnetic-Acoustic Detector

Work began in FY89 on magnetic-acoustic mine detection, to transition to development in FY92. As of early 1989, system integration and sea trials were scheduled for FY91. In theory, the use of 2 detection methods should greatly reduce the false-alarm rate in minehunting. It is also possible that the plan is to use some form of magnetic resonance to detect particular explosive compounds, even if the mine casing is nonmetallic.

This project is distinct from efforts to develop countermeasures to buried mines.

◆ MIDS

Modular Influence Minesweeping System was a new start planned for FY90. It was begun in accordance with a CNO memorandum of 14 February 1986.

◆ MTDS

Mine Countermeasures Tactical Environment Data System is a current project begun in accordance with a CNO memorandum of 7 April 1986. In this case the tactical environment includes background magnetic fields and tides.

◆ Project Kingfisher

Kingfisher was a 1988 emergency project for mine detection and evasion, begun after the mining of the frigate *Roberts* and funded out of the JCS War Chest (\$30 million). Projects funded by Kingfisher were the use of the Plessey Mirror Sonar, the test of Magic Lantern, the Hughes MMS (described in the Antiaircraft Warfare section), and Project Midnight. Project Midnight was a Diagnostic Retrieval Systems (DRS) attempt to use fields of active sonobuoys plus a processor. The MMS was intended primarily to detect floating mines. Of these prototype systems, the MMS and the Mirror Sonar were actually deployed to the Persian Gulf.

◆ Remote Minehunting

The current mine-countermeasures program includes development of a system employing multiple remotely controlled vehicles operated from a single platform in amphibious objective areas and in other areas where conventional forces are not available. As of early 1989, FSED was scheduled for FY92.

◆ SISS (SYQ-12 and -13)

UNISYS's Shipboard Integrated Route Survey System is a software package hosted on various computers. The existing old MSOs use the SYQ-12 Integrated Shipboard System (ISS), running on a DTC I computer (HP 9020). SYQ-12 was installed on board the first MSO in 1985 and was used in the Persian Gulf. There it operated with Sea Rover ROVs (which were bought specifically to operate with this system). It also has a Route Survey Data Management System. A DTC II version of SYQ-12 is under development but had not yet been delivered as of mid-1990. All U.S. COOP minehunters also have the ISS (SYQ-12). SYQ-12 has also been sold (FMS) to Egypt for use on COOPs, with the EG&G 260 towfish and the Super Sea Rover vehicle.

The new *Osprey* class has the Navigational Command and Control System (SYQ-13), which is basically the SYQ-12 software hosted by a fully militarized 68020-based computer with a mass memory (which has no separate AN designation), a high-resolution color display, a tape driver, a printer/plotter, up to 8 navigational aids, and MCM sensors (which can include side-scan and hull sonars).

◆ SSDS

Single Ship Deep Sweep was a new start in FY90 to meet an OR issued 8 March 1983. Presumably, it is a U.S. equivalent of the single-ship version of the British EDATS.

◆ Surf-Mine Detection and Destruction/RSWMCS

In 1989 the navy reported that in FY88 it had completed laboratory tests of a system for laser mine imaging to detect mines in the surf zone, which would impede an amphibious assault. At the same time, linked miniature shaped charges had been demonstrated as a means of neutralizing these mines. The laser surf-mine work continued through FY89, and the miniature shaped charges were incorporated in a new mine-destruction system (not named). This work may refer to a new program, RSWMCS (rapid shallow-water-mine countermeasures system), for which formal requirements were prepared in FY90, looking toward an initial contract award in FY91.

This is a Marine Corps system. The ultimate goal is to reduce

size to the point where the laser detector can be carried by a UAV.

The FY89 program also included exploratory tests of high-powered microwave technology for mine destruction (presumably through EMP-like attacks on mine electronics). The announced FY90 program included completion of development of the airborne mine-detection-system image processing, with testing scheduled for completion during FY91 (this is not the Northrop ALARMS system).

◆ EDO Model 819

A shipboard derivative of the EDO Mk 105 airborne mine-countermeasures system, 819 is called MIMS (Modular Influence Minesweeping System) by the company. 819 employs a gas-turbine generator and a tow cable for both acoustic and magnetic sweeps, the cable carrying magnetic electrodes and towing an acoustic fish. MIMS is intended to equip craft of opportunity; the towing reel and winch weigh, together, only 5000 lb (it takes up only about 10 ft² on the ship's deck).

◆ EDO Model 910

See the ASW section (Model 900/910).

◆ Model 260

EG&G Environmental Equipment's Image-Correcting side-scan sonar fish can be towed at up to 12.7 kt, covering a 600-m swath on each side, with a resolution equal to 0.25% of range.

◆ Phantom

Deep Ocean Engineering's modular ROVs are used for tasks such as ship inspection, bottom survey, harbor patrol, and mine countermeasures (for which the HVS4 version was specifically designed). HVS4 weighs 82 kg, develops more than 68 kg of thrust, and sustains a speed of more than 4 kt at depth. It has been used with the Canadian Mesotech 971 sonar and with a 20-kg payload release. The vehicle has 2 thrusters aft and can sit on the bottom using a sledlike frame. As of late 1989, nearly 150 had been sold, including 2 HVS2s for the U.S. Navy Coastal Systems Center (for airborne mine countermeasures), 2 HVS4s for the EOD (explosive-ordnance disposal) Technical Center, HVS2 for AMCM, and Phantom Supers for the Royal Navy and Royal New Zealand Navy.

◆ RCV-425

Hydro Products' ROV is controlled and propelled by 4 thrusters (2 axial, 1 vertical, 1 lateral), all driven by a 10-HP hydraulic system. It typically carries an LLLTV camera and 4 high-intensity lights; a sonar is optional. The tether cable is 1200 ft long and 0.46 in in diameter. Maximum depth is 1000 ft. Dimensions: 47 (long) × 39 (wide) × 23 (high) in; weight is 200 lb.

◆ Recon IV-S

Perry Offshore Inc.'s ROV has 4 thrusters and automatic depth control, and all components are separately controlled from the surface. The ROV has 160 kg [353 lb] of positive buoyancy, available for payload, and it also has 38 spare connections for additional equipment. It can accommodate sonar, cameras, and spotlights in its open frame. Speed: 3 kt forward, 1 kt vertical or lateral. Maximum depth is 457 m [1500 ft]. Dimensions: 2.06 (long) × 0.9 (wide) × 0.85 (high) m; weight is 457 kg [1007 lb].

◆ Team Rockwell MCM System

This system has been proposed by Rockwell Autonetics Marine Systems division with 2 Canadian companies, ISE (International Submarine Engineering) and OSL (Offshore Systems Ltd.). Rockwell will provide its Mil-Spec console and, presumably, system integration; ISE provides the remotely operated vehicle, and OSL the navigation. The initial proposed application is on board the projected Canadian mine-countermeasures craft (MCDVs).

The ISE Dolphin semisubmersible vehicle cruises at 12 kt (26 hr endurance) with a maximum speed of 16 kt (endurance

325 nm). Dolphin carries a side-scan sonar, data from which are transmitted back via VHF radio link. The single-beam side-scan sonar has detected targets at 500 m at up to 6 kt. Two Dolphin vehicles have been supplied to DARPA to aid in the development of an autonomous minehunting vehicle for future COOPS and minehunting helicopters. In theory, Dolphin could find targets for later investigation by British Trail Blazers, smaller ROVs made by ISE (see above).

◆ TP Scout

Katema Aerospace's ROV uses propellers at either end, operating at various combinations of cyclic and collective pitch, for propulsion and control (presumably, this is equivalent to the operation of a coaxial helicopter, turned on its side). Maximum speed is 8 kt, and maximum depth is 300 m [about 1000 ft]. Dimensions: 0.51 m (diameter) $\times$ 2.18 m.

◆ Viper Mk 1

Allen Osborne Associates' ROV is powered either by batteries or by a fuel cell driving 4 thrusters. It is controlled by a fiberoptic umbilical out to 2000-m range; the pilot uses a joystick and a mouse. The sensors are a high-resolution sonar (200-m range) and an LLLTV (CCD camera). Maximum speed is more than 8 kt (the ROV dives or ascends at 1.5 m/sec); maximum depth is 200 m. Dimensions: 0.5 (wide) $\times$ 0.53 (high) $\times$ 1.88 (long) m; weight is 46 kg.

YUGOSLAVIA

Yugoslavia has the following river sweeps: Type PEAM magnetic and acoustic; Type AEL-1 explosive; Types MDL-1 and -2 mechanical.

ADDENDUM

In December 1990 Aeritalia and Selenia merged to become Alenia. Consorzio Sistemi Navali Selenia-Elsag will continue under its present name, taking over the Elsag holdings in Welse, USEA, SEPA, and the French CSEE (40% control). However, a proposed joint venture among Matra, OTO Melara, Breda, SMA, and Officine Galileo, to have been called OTO-Breda *Missile e Sistemi*, apparently will not go ahead.

As of 1 January 1991, Bofors and FFV had merged most of their defense (ordnance, as opposed to electronics) activities in a new joint company, Swedish Ordnance-FFV/Bofors. Bofors had already absorbed the former Philips military electronics arm, PEAB (which is now trading as BEAB).

As of January 1991, the name MEL ceased to exist; the company became part of Thorn-EMI Sensors (the headquarters of the Thorn-EMI Sensors division was moved into the former MEL headquarters).

A project to combine BAe missiles and Thomson-CSF missiles divisions under the name Euromissile was canceled in mid-March 1991.

The U.S. FY92/93 budget issued in February 1991 terminated the following weapons programs: RAM (later reinstated), ASRAAM support, 16-in gun ammunition improvement, high explosive antiarmor, 16-in gun ammunition, Excalibur (LRCSW) missile, Bigeye chemical weapon, B-90 nuclear depth bomb, low-cost seeker, 3-in/50 gun ammunition, and 5-in/38 gun ammunition. Other announced terminations included an electro-optical sensor, RECO (remote minefield control), the new CAINS, NCCS shore systems, directed-energy countermeasures, cooperative engagement, C3 countermeasures, SAR-8, NAAWS, CORT (Mk 92 Mod 6), ROTHr procurement, and SQR-18 backfits. Some of these programs may survive under other designations, to be financed as parts of other programs, and others may be restored by Congress or by supplementals. Both remaining battleships are to be retired, hence the elimination of 16-in gun improvement programs. There is good reason to expect other programs to be revived.

A supplemental program presented to Congress after the cease-fire in Kuwait called for procurement of 290 Tomahawks, 8 SLAMs, 2033 HARMs, and 5000 Mavericks (air force version).

Readers are cautioned that the FY92-93 U.S. budget figures in this addendum are those proposed by the administration; they often change radically between proposal and final enactment (for example, Congress rejected the cancellation of Sea Lance and V-22 during 1990).

SURVEILLANCE AND CONTROL

CANADA

In August 1990 the underway replenishment ship *Protecteur* was fitted with ADLIPS specifically so that she could receive Link 11 data and so carry the same air picture as her 2 consort destroyers in the Persian Gulf.

◆ SHINPADS

This system equips the new Canadian *Halifax*-class patrol frigates. It uses much of the architecture originally developed in the 1970s, which is broadly similar to that implemented by Honeywell/Hughes in the H930 series. The system operates in 3 modes: automatic, semiautomatic, and manual. The normal mode is semiautomatic; the tactical situation builds relatively slowly. The automatic mode is for very fast engagements (the command can control engagements by veto). In the fall-back manual mode, the operator assigns weapons, begins engagements, and reconfigures the system to account for failures or damage to its components.

The 32 computers (UYK-502s, UYQ-504s, UYK-505s) of a SHINPADS system are linked by 4 triaxial cables, only 2 of which need be active for 100% capability. Each cable can carry either system data or electrical control messages. The 10-Mbit/sec UYC-501(V) serial bus, equivalent to ten 1553B buses, was developed especially for SHINPADS. It uses only about 10% of its 10-MHz bandwidth. Similarly, 60% of total computer power

could be lost without the loss of full system capability. All of the display consoles are interchangeable. SHINPADS is unique in its direct integration of EW (including chaff launching) into the combat system's data bus. The current word length is 16 bits (sometimes ganged to 32). All the computers are to be upgraded to UYK-507s (SHINPADS currently uses a mix of UYK-502s and -505s).

In a Canadian patrol frigate, there are 13 SHINPADS standard display consoles (UYQ-501s) in the operations room and another on the bridge, plus a U2049 display used to monitor and reconfigure the system after damage or when changing modes, and 2 STIR (FCS) consoles. The operations room (CIC) is divided into 2 teams, AAW/Surface (led by a sensor weapons controller) and ASW (led by the assistant sensor weapons controller). The AAW/Surface group includes the 2 STIR operators, the track supervisor (with 2 radar tracker operators), and the EW supervisor (with an ESM operator and a communications-intercept operator). The ASW group includes a sonar-control supervisor (to supervise the operators of the hull sonar, towed array, and sonobuoy processor [Jezebel]) and the ASW-aircraft controller. The teams in the operations room are supervised by the operations room officer, who stands at an additional standard console, and there is also a standard console in the operations room for the commanding officer (but the communications-intercept console is not a standard console).

The separate, integrated, machinery-control system (SHIN-MAX) has its own SHINPADS data bus. Very early on (late 1970s, certainly before 1983) there was some interest in integrating the operations room with machinery control, but that idea was dropped, and a different (CAE) system monitors the machinery and ship's condition.

The Link 11 data terminal set in this system is USQ-76.

◆ HINPADS/MSDHS

HINPADS was formally dropped in mid-March 1991 in favor of a UNISYS (Paramax) Mission System Data-Handling System. MSDHS will conduct the back-seat functions, using a 68000-based computer, IPDS (integrated processor and display system), based on the UYK-507. It will incorporate the operator-machine interface work originally done for HINPADS and will have real-time software. Final negotiations were conducted in March 1991. Four consoles in the back of a helicopter, a 1553B bus, and 6 computer cards in the cabinet will be integrated with the front seat and tied to a European front end. Paramax is the integrator of the avionics systems. Paramax has also developed an alternative scaled-down (2-seat) version with color, windowing, and multipurpose consoles. This version will have both joystick and keyboard data entry. There is still some question as to whether this helicopter will have FLIR (PAV) and MAD, but it will have a dipper and buoys.

FRANCE

◆ Super-Étendard Tactical Data System

Here is some additional information on the Super-Étendard system. The prototype upgraded Super-Étendard began flight tests on 5 October 1990. A total of 48 aircraft are being upgraded (3 prototypes, plus 15 per year from 1992 to 1995). The airframe modification is to extend the aircraft's service life to 2005. Improvements include installation of an Anemone TWS radar (in place of the current Agave), a new inertial platform, a new wide-angle HUD (which can also display TV and FLIR images), the Sherlock RWR, extra stores attachment points, a provision for night-vision goggles, a HOTAS control, and a new central computer (SAGEM UAT 90 in place of the earlier UAT 40).

◆ TAVITAC 2000

A 1991 Thomson-CSF brochure shows that the system is built around a duplicated Ethernet LAN carrying up to 15 high-resolution Vista consoles, with separate interfaces to the tactical computers (including redundant computers) and redundant interfaces and through computers to specific sensors, weapons,

and data links. These devices are also connected directly to the main Ethernet for full redundancy. All the computers use 68030/68040 processors with 1–4 CPUs and up to 4 Mbytes per computer. Each Vista console has a 1280 × 1024-pixel, high-resolution, color screen, 2 software-defined touch-sensitive keyboards, and a 32-bit processor (which can process up to 800 tracks). It is programmed in ADA. The console can display up to 300 tracks (256 in color) and has windowing and zoom capability.

◆ Vega

Vega was never a full CDS; it was a partial system grown from a GFCS. The original analog gun computer, BCH, could manage fire control and also make ballistic calculations. All examples in service are being replaced by digital (16-bit) CDE computers developed and manufactured by Thomson-CSF. CDE is especially adapted to gunnery calculations; it is not fully reprogrammable. It is the current standard French navy fire-control computer.

GERMANY

Here is some additional information on German tactical data systems:

◆ AGIS

There are 2 versions, S143 and S143A. In each, the Signaal WM27 radar feeds a horizontal tactical table (*Taktischer Bildschirm horizontal* or TBh) with tactical data (*Taktischer Datenanzeige* or TDA), as well as feeding the fire-control computer (*Feuer Leit Rechner* or FLR). The FLR is connected to the command/control computer (FUR), which is connected to the tactical table (TBh). In the S143 version, besides controlling weapons, the FLR also drives a series of vertical consoles (2 TKG and 1 output console, *Ausgabekonsol* or AKG). The FUR is connected directly to the console of the Norwegian-supplied SR-1A ESM system. In the S143A version of the system, the FLR drives a single vertical output console (AKG). The FUR is connected to a vertical display console (multipurpose display console, *Mierzweckdarstellungskonsol* or MDK) and to the FL1800 ESM system.

The S143 version uses a UYK-7 computer with USC-27 as its data terminal set; the S143A version uses a TE-905 as its data terminal set. The S143 version can operate simultaneously in HF and UHF.

AGIS means *Automatisiertes Gefechts- und Informationssystem* (automatic combat evaluation and weapons-control system). It was the second generation of German CDSs, after SATIR I.

◆ PALIS

PALIS (*Passiv-Aktiv-Link-Lage-Informationssystem*) is a lightweight tactical data system for fast attack boats (S148 class), for the Hamburg-class destroyers (Z101A class as modernized), and for the new fast minehunters (M343 class). In each case PALIS is built around a UYK-20A computer. S148 and Z101A use the same version, with Sanders Mk 95 and Mk 95 Mod 1 consoles and with TE 905 and TE 237 data terminal sets. The minehunter version uses the new KAE BM 802-61 console and the TE 237 data terminal set. PALIS's functions are navigation, tactical navigation, target tracking, identification, indication of special (fixed) points, tactical bearing indication, ESM integration, weapons designation, Link 11, alerts, and data extraction.

PALIS appeared in the mid-1970s.

◆ SATIR

There are 3 versions:

SATIR I for *Lutjens* (modified *Adams*)-class (Z103-type) destroyers, which have now been modernized (Z103B class). Although SATIR originally used a USQ-20B computer, the current (modernized) version uses a UYK-7. It incorporates a version of the SYS-1 integrated ADT (IADT). SATIR I incorporates 3 OJ-194(V)/3/UYA-4 PPI consoles (2 for SYS-1, 1 for the FL1800S

ECM system), 11 OJ-7979(V)/UYA-4 multipurpose consoles (each with an associated digital indicator), a disk memory unit (U 1647/1, with 500k 32-bit words; data rate is about 127 kwords/sec), and a USQ-69 data terminal set. SYS-1 includes a range-height indicator (IP-1117/UYA-4). This equipment is typical of contemporary U.S. NTDS practice. The Z103B combat system includes an SPS-67(V)1 surface-search radar in place of the earlier SPS-10F and a DSQS-21B sonar in place of the earlier SQS-23L. The MFCS is Mk 74 Mod 6, and the GFCS is Mk 86 Mod 8. This version controls 2 RAM missile launchers.

The SATIR I operational program was written by German officers at the U.S. naval programming center at San Diego. SATIR originally corresponded to the U.S. NTDS. It tracked the ship's position automatically and conducted navigational calculations (such as collision points and CPAs). It kept track of (and provided rate-aided projection of) radar-target data entered manually. It provided computer assistance to maintain a radar and sonar plot and could pass target data to the weapons-control system (and calculate whether particular targets were engageable). It also exchanged data with other units via Link 11. It was not integrated with the ship's ESM system nor with the ship's underwater FCS. The Z103B system enjoys improved AAW performance through automatic radar-target detection and tracking (SYS-1), incorporates a new GFCS (Mk 86), can control a long-range antiship missile (Harpoon) and a new AAW weapon (RAM), and is integrated with the ship's ASW FCS (it mediates between the ship's sonar and her Mk 114 underwater FCS) and with her ECM system (FL1800S; it mediates between the FL1800S sensor and its transmitter).

SATIR II for the *Bremen* (F122) class is built around a UYK-7 computer, which is powerful enough to handle all shipboard sensors and weapons (Z103 had a separate Mk 114 underwater FCS and separate missile and gun FCSs). All weapons and sensors operate through multifunction consoles (MZKs). This version incorporates automatic radar-target detection and tracking and can engage air targets automatically (it chooses the weapon most appropriate to a given target). It supports ASW using both shipboard weapons and the embarked helicopters. Like the Z103B system developed somewhat later, SATIR II integrates ESM with other shipboard sensors.

SATIR III for the new F123 class is built around a UYK-43 computer. This system has 12 display consoles and 2 Link 11 data terminal sets.

INTERNATIONAL

Here is further information on Western data links:

Link 1 This ground-to-ground link is between sector observation centers in an air-defense environment such as UKADGE. TADIL-B is similar but uses the Link 11 (TADIL-A) format and a different speed of transmission.

Link 4 This interceptor-air-control link was used by both France and the United States. It has been replaced in U.S. service by Link 4A, which is used for carrier-controlled (all-weather) approach as well as for air defense. Link 4B is a ground-to-ground land-line link. At least the original Link 4 used 70-bit messages (each bit being 200 microsec in duration, for a total of 14 msec), each of which included a synchronizing pattern, a start pulse, an aircraft address, a message number or label, 2 information groups, and parity-checking bits. The link operates at a fixed frequency within the 300–325-MHz band by frequency-shift keying. There is no overall net-control clock; an airplane receiving a message uses the synchronizing pattern to set its own clock to receive. Even so, the finite length of each message sets a practical limit on the number of aircraft that can share a single net. A controlling transmitter must be able to send messages to all its aircraft in sequence, and there must be some allowance for message feedback. There must also be some short time between messages. Practical net size is limited by allowable time-lateness of messages. For example, 20 messages would take something more than 0.28 sec, so 1 of 20 aircraft would have to wait at least that long for an updated enemy aircraft position.

Link 5 This ship-to-shore link was to be used with Link 11 but was abandoned.

Link 7 France uses this air-traffic-control (point-to-point) link. Because only France used this link, the Link number was not adopted by NATO.

Link 11 These are the export versions for E-2C aircraft:

Link Delta for Egypt (reportedly because Delta resembles a pyramid)

Link Pi for Israel (eleven with a line above it)

Link Sigma for Singapore

Link 13 This smaller version of Link 11 was developed by France, Belgium, and Germany in 1962–64 but was ultimately dropped.

Link 15 This projected (abandoned) link was to have allowed noncomputer ships to send teletype data to Link 11 ships.

Link G This air-ground link by Ferranti was presumably equivalent to Link 4.

Link W This is an unlicensed derivative of Link 11 (but is not compatible with Link 11) developed specifically for the Saudi frigates. Its name comes from the "W" in Sawari, the code name for the French-Saudi naval arms project.

Link Y This current Ferranti version can transmit up to 4800 bits/sec, using a TDMA network with up to 30 subscribers. As of 1985, Link Y had been sold to Brazil and Egypt. Link Y was offered for export on board Tornados, so it may be in service in Saudi Arabia.

Link Z This link typically transmits at 75 bits/sec. It is a broadcast system, so 1 terminal can transmit to any number of subscribers.

JAPAN

◆ Bottom Surveillance Arrays

Japan maintains 2 surveillance centers at the southern and northern entrances to the Sea of Japan (Tsushima Straits and Straits of La Pérouse), using a combination of bottom arrays, shore radars, and optical observation. Because they are barrier arrays, the bottom arrays used would not have been long-range SOSUS-type installations; initially, they were probably upward-looking devices. In the late 1960s they were replaced by a total of 19 LQO-3 arrays; the first 2 of 5 sets in the Tsushima Straits were installed in 1968. In the 1980s these devices were upgraded to LQO-3As. At that time an official report suggested that a diesel submarine operating at less than 6 kt had a 70% chance of being detected at a range of 1000 yd and a 15% chance of detection at 3000 yd. Such figures would be entirely acceptable in a barrier, as opposed to an open-ocean, tracking system. In the 1970s development of the lower-frequency LQO-4 began. It is a longer-range system and initially coordinated operations of P-2J patrol aircraft.

Japan is currently deploying SURTASS-type surveillance towed-array ships with U.S. technical crews; Japan and the United States share their surveillance data.

NETHERLANDS

◆ SMCS

The Signaal Modular Combat System is the fully distributed successor to the centralized SEWACOs. It will probably be renamed in view of the merger with Thomson. The fire-control module is STING (similar to the earlier STIR but with hydraulic rather than electric drive, using the 1.2-m dish), and the radar will probably be SMART/MW-08. The Signaal approach has been to link separate building blocks by bus interface modules to a fiber-optic bus (which has greater capacity than the Ethernet bus of the M-class frigates). This type of architecture can be fully open, but it is not entirely clear yet whether Signaal will go all the way in that direction.

At this writing the standard SMCS console is still SIGHT (Signaal General-Purpose High-Resolution Tactical Display), incorporating a 19-in, high-resolution, raster-scan, color screen, a 12-in monochrome or 15-in color television screen (either atop the main display or to its left), a keyboard with trackball, a display processor, and a bus interface. Each console can be linked directly with up to 4 subsystems.

◆ STACOS

The Turkish and Portuguese MEKO 200 frigates have the original STACOS CDS. Mod 2 is in the Greek frigates. A Blohm & Voss report dated March 1991 shows Mod 3, rather than CoSys 200, in the Turkish Track II frigates. However, these ships are still listed as using Plessey-Contraves sensors and fire controls rather than Signaal's: forward, the AWS-9/996 air-search radar and the Contraves TMX and TMKu rather than DA-08 and WM25; and aft, STIR and TMKu rather than STIR. Both versions use the Dolphin target-indication radar (the Portuguese and Greek units use MW-08 instead).

UNITED KINGDOM

◆ System 500

As of March 1991, this system was being offered to Brunei, Malaysia, and another potential Far East customer. Ferranti's bid to Korea was a version of CAAIS.

USSR

◆ "Second Captain"

In the *Moskva* class the Soviets introduced a new command-assistance computer, sometimes called the "Second Captain." Given tactical data, such as the designation of an approaching attack airplane, the computer provided an optimum course of action. This is not too different from the initial Soviet tactical computer application on land, in which a computer chose among several precanned courses of action. This sort of application derives from the Soviet view that war is a scientific endeavor, in which the optimum course of action in any situation can be determined mathematically (a concept that radically reduces any need for individual initiative). Because of the state of Soviet computer development in the late 1960s, the inputs describing the tactical situation cannot have been very elaborate. On board the *Moskva*, for example, the "Second Captain" did not (reportedly) maintain any sort of current plot. Instead, it provided a series of textual recommendations, with calculated data (e.g., "You have 45 seconds within which to react to the approaching A-7 aircraft"). The computer display, moreover, was not in the CIC (which the Soviets designate BIP, battle information post) but in a separate guarded space. Although there was apparently provision for automatic input, actual input seems to have been by voice and written message.

In the early 1970s this system also appeared on board the other Soviet flagships: the converted *Sverdlov*-class cruisers and the big submarine tenders. It was not on board Kashin-class destroyers.

SOVIET NAVAL COMMUNICATIONS ANTENNAS

◆ Data Links for Missile Targeting

Band Stand This is probably an air-to-ship data link for SS-N-9 and SS-N-22 targeting, first installed on board Nanuchka-class missile corvettes. It is also carried by *Sovremennyy*-class destroyers, Tarantul-II (SS-N-2C) and -III class missile corvettes, and the Sarancha hydrofoil.

Fish Bowl This predecessor to Light Bulb was on board some Nanuchka-III-class missile corvettes (mounted 1 on each side of the mast, above the ESM radomes). This receiver is also on board the Sarancha and some Nanuchka-Is.

Light Bulb This satellite- (or air?) to-ship data link is associated with the SS-N-25 missile on board *Sovremennyy*-class destroyers, Tarantul-II and -III class missile corvettes (associated with

SS-N-2C in Tarantul-II), and some Nanuchka-III-class missile corvettes (1 on each side of the mast, above the ESM radomes).

Plinth Net This is probably a transponder for use with SS-N-3 missiles, on board some (but not all) Kynda and Kresta-I class cruisers (exceptions are the Kresta-class *Vladivostok* and Kynda-class *Admiral Golovko* and *Varyag*). Plinth Net is a large parabolic antenna resembling an air-search radar, but it is located relatively low in the ship's superstructure on each side and is thus ill-suited to any air-search role. It may provide missile-guidance channels additional to those of the Scoop Pair antenna that usually controls SS-N-3.

Punch Bowl This satellite-to-ship data link is associated with the SS-N-19 missile and is carried on board carriers, cruisers, and Oscar-class submarines.

◆ Communications Antennas

The great variety of antennas on board a single ship suggests that many are special-purpose. Most are omnidirectional; presumably, those in radomes (Bell series and Fig Jar) are directional. Much of the information below is derived from a published list associating particular classes with particular antennas; it is probably incomplete and should be treated with some caution as a guide to patterns of antenna employment. However, if the pattern given below is correct, it seems likely that Bell Crown is a directional system superseding Fig Jar; Bell Crown is limited to modern large-ship classes with ASW capability, ships that might be expected to operate together. Some of the designations given in the accompanying photos do not jibe with the list below (they may be unofficial).

In addition to the designated antennas, modern cruisers and destroyers are equipped with HF and HF-MF whips (varying in length from 10 to 50 ft) and with MF cage antennas strung between their masts (e.g., with 4 wires and circular spreaders every 20 ft). Submarines have telescopic HF antennas, and Park Lamp can reportedly receive VLF signals down to 30 ft below the surface.

Bell Crown Kiev, Moskva, Kirov, Slava, Kara, Kresta-II, and Udaloy classes.

Bell Nest Tarantul-II-class missile corvettes only.

Big Ball Satellite communications, superseded by Low Ball. Associated with Molniya and Raduga satellite systems.

Bike Pump Broad-band end-fed UHF dipole, recognizable because it has two thick tubular segments joined by a thin tube. Kara, Kresta-II, Kresta, Mod Kashin, Krivak, Grisha, Mirka, Petya, and Poti classes.

Bird Dipole/yagi UHF antenna. It consists of yagis at the top and bottom of a vertical mast (with 4 dipoles on the upper yagi and 3 on the lower), and it has a single horizontal dipole at roughly the midpoint of the mast. A monopole antenna extends vertically above the upper yagi.

Bow Split On board some Grishas.

Box Yoke UHF communications antenna, on board Kirov, Kashin, Krivak, Grisha, Petya, and Natya.

Bread Knife Kresta, Mod Kashin, Riga, Grisha, and Petya classes.

Brick Spring High-gain horizontal UHF helix antenna (tube) with circular ground plane (with circular holes cut in it).

Cage Bare VHF dipole antenna, on board all combatant ships; standard VHF antenna down to missile and gun boats.

Cage Cone VHF antenna, on Kiev, Moskva, Kirov, Slava, Kara, Kresta-II, Kresta-I, and Kynda classes.

Cage Stalk VHF (broad-band dipole) consisting of 2 vertical tubes (cages) tapered down to join at the middle with a yardarm. On Kiev, Moskva, Kirov, Kara, Kresta-II, Kresta-I, Kynda, *Sovremennyy*, Udaloy, and Mod Kashin classes.

Cat Cage Mirka class.

Chuck Tube Dipole antenna, supported at its center.

Coin Grass Alligator class.

Cross Fold Polnocny class.

Cross Wedge Kashin, Nanuchka, Poti, Andryusha, Vanya, and Alligator classes.

Cuff Pair Petya class.

Farm Loaf On board Kashin, Koni, Riga, Grisha, and Mirka classes; formerly on Kotlins and Kildins. It is carried at the end of a yard and is a rectangular (rather than cylindrical) radome, tapered at its top.

Fig Jar Squat cylindrical radome pointing up at the end of a yardarm. On board Kresta-I, Kynda, Kashin-II, Mirka, Petya, and Poti classes, hence presumably associated with an ASW data link. Bell Crown may have been the successor device.

Fish Spine On board most modern combatants, from Krivak-class frigates up. A long yagi, it looks like a directional television antenna. Presumably, this is a directional UHF antenna.

Grid Bow Unidirectional, vertically polarized, broad-band UHF antenna. It consists of a vertical Bow Tie dipole (2 squares with their sides at 45 deg to the vertical) in front of a vertical screen.

Grid Quad Mirka class.

Half Key Moskva and Sovremennyy classes.

Hat Box Kiev, Moskva, Kara, and Kresta-II classes.

Long Fold Standard antenna, on board most combatants from the Pauk class up. May not be on board *Slava*, *Sovremennyy*, and Kashin as built.

Long Wire MF/LF dipole, on destroyers and similar ships.

Low Ball Satellite communications, e.g., on board carriers.

Pole Star Moskva, Kynda, *Udaloy*, *Zhenya*, *Ivan Rogov*, *Ropucha*, and Alligator classes.

Pop Art Standard VHF antenna on corvettes and larger warships from Kashin class onward. It consists of dipoles bent into a pair of rhomboid shapes at angles to each other. Variants A through D are in service.

Quad Rods *Slava*.

Rib Cone Vertically polarized, omnidirectional, broad-band VHF antenna, with 10 horizontal dipoles at its upper end forming a ground-plane reflector. There are 2 cones, 1 at the top (under the dipoles) and 1 lower down consisting of stays to the deck. This antenna is somewhat similar in appearance to the U.S. broad-band antenna used with NTDS. Kashin, Krivak, Petya, and Alligator classes.

Ring Web Krivak, Mirka, and Polnocny classes.

Round Web Kashin, Krivak, Mirka, Poti, SO 1, Osa, Yurka, Alligator, and Polnocny classes.

Slant Blade Polarized array of broad-band VHF blade antennas at a 45-deg angle, typically pointing up from under a yard.

Soup Cup Mirka class.

Shot Dome/Shot Rock Small antennas in vertical radomes, carried on board most combatants.

Sprage Star Horizontally polarized VHF dipoles at different angles to the horizontal. Mirka class.

Sprat Star Dipole array, listed here as an ESM antenna but sometimes considered a communications antenna.

Straight Key VHF dipole antenna, on Kashin, Mirka, Petya, SO 1, Osa, Shershen, Natya, T.43, Sonya, Zhenya, *Ivan Rogov*, and Polnocny classes.

Straight Pole Kara, Kresta-II, Krivak, Yurka, and Polnocny classes.

Straight Rail Moskva class.

Straight Tee Kashin and Vanya classes.

Stub Brace Broad-band, horizontal crossed dipoles, passing one above the other through a vertical circular sleeve (horizontally polarized).

Top Star Mirka class.

Vee Bars Two cones at 90 deg with additional crossed dipoles at their ends. The Vee series are long-range, directional HF antennas associated with flagship operation, especially the *Kiev* class. They are also on board some scientific auxiliaries operating far from home waters.

Vee Cones HF: 9-m cones at 70-deg angle. On board 1 Don- and 1 Ugra-class auxiliary (flagship). This was the first in the series, originally on board 2 *Sverdlov*-class cruisers modified as flagships.

Vee Tubes HF: 8.60-m cones at 90 deg. *Kirov* class.

Wedge Pair Mirka and SO 1 classes.

UNITED KINGDOM

◆ CANE I/II

CANE I/II use the Kongsberg KS500 computer and provide a 40-character × 12-line interactive display. They can indicate targets to an associated FCS. Capabilities are autotrack and semi-autotrack, CPA calculation, intercept and relative velocity calculation, autopositioning on charts, autopositioning print-out, and creation of a labeled plan display (LPD), i.e., of a synthetic-video PPI picture.

◆ Captain's Combat Aid

In December 1990 Thorn-EMI received a contract to develop a version of the Captain's Combat Aid for the ADIMP (ADAWS upgrade) program.

◆ DLPP

In 1986 Ferranti received a contract for 17 data link preprocessors built around Argus processors, for Type 22 frigates with CACS combat data systems. DLPP constructs and maintains a track file (up to 100 tracks) based on Link 11 data; it acts as a buffer. Because DLPP is external to the ship's main CDS, it can be modified relatively easily to accept data from other links, such as Link 16. Presumably, CACS originally accepted only Link 10 data.

A DLPP is also part of the ADIMP upgrade for Type 42 destroyers.

◆ KDX Combat System

As of early 1991, the Korean navy had reportedly decided to choose between the Sema-Dowty SSCS and the Swiss-German CoSys 200 for the combat system of its next-generation destroyer (KDX). The main sonar alternatives were reportedly the KAE DSQS-23 and Spherion. The program called for 8 destroyers optimized for antiship warfare, to be followed by 8 for AAW and 8 for ASW. At this writing it is by no means certain that the program will proceed as projected.

UNITED STATES

◆ SOSUS

The information that follows comes from an official history written about 1977 and declassified at the end of 1990. Although a great deal has happened since 1977, this account gives the first declassified picture of the logic and direction of SOSUS's development.

The contract for a LOFAR system was let to Western Electric in the fall of 1950. The prototype shallow-water array at Sandy

Hook was in place by the beginning of May 1951, and the first 40-hydrophone array at Eleuthra had been installed by January 1952 for tests beginning in April 1952. After their success, the CNO directed in June 1952 that 6 deep-water (1000-fathom-deep) arrays be installed in the Atlantic, the first at Bermuda, as the initial portion of Project Caesar, which was the original name for SOSUS. The first system test, using the Eleuthra and Bermuda arrays and the ASW submarine K-1, was conducted between 26 April and 7 June 1954. Sound data were all relayed to an analysis center at Norfolk, and sonobuoy-equipped aircraft were able to acquire the targets 90% of the time. The experimental sites detected submarines as far away as 600 nm, although average ranges were 300–400 nm. The full Caesar system consisted of Atlantic and Pacific barriers. The Atlantic sites (8 of which were operational by early 1956) were relatively far offshore because the continental shelf extends well out to the east; the Pacific sites were close to the steeply shelving coastline. By January 1956 the Atlantic sites were reporting 3400 contacts/month, of which 64 were classified as non-U.S. submarines. Most contacts were not submarines.

At this time, SOSUS was supplemented by submarine patrols (largely for electronic reconnaissance) in the North Atlantic and North Pacific, by electronic intercepts (from Norway) covering the operating area of the Soviet Northern Fleet, and by surveillance of the Northern Pacific mounted from the Aleutians and Japan. Sound surveillance was supplemented by 3 HF/DF networks (2 Pacific, 1 Atlantic), which were being modernized to deal with very short, time-compressed transmissions (the goal in 1960 was an ability to deal with a 1-msec signal). The new systems were installed during FY61–64. In an emergency, submarine barriers would be deployed in sensitive areas and strategic choke points. The Caesar system itself was very largely an extended form of coastal cover. Work was proceeding on a shallow-water extension (to protect the shoreward terminals of the offshore arrays) and a deeper-water extension.

Caesar was based in U.S. waters. In the Atlantic, the system's effectiveness was inherently limited by the Mid-Atlantic Ridge, which blocked sound transmissions from the Eastern Atlantic. In the Pacific, U.S. territory (in the Aleutians) extended toward the main base of the Soviet Pacific Fleet, Petropavlovsk. The OBOE array at Adak (1962) was successful in covering Petropavlovsk as well as the transit area running toward the mid-Pacific. Its success led to the cancellation of the then-current SOSUS-expansion scheme in favor of a new emphasis on forward-area listening. One advantage of listening in the areas through which Soviet submarines had to transit (rather than in their likely patrol areas) was that transmitters were generally louder (since they had to make a substantial speed to reach their patrol areas within a useful time). New arrays in North American and Western European waters extended coverage into the Norwegian Sea and also into the Eastern Atlantic (Project Backscratcher) early in the 1970s. At about the same time, arrays were installed to cover areas of the Western Pacific and mid-Pacific. In many places, the SOSUS coverage was precise enough to cue ASW aircraft directly, but Pacific arrays were sometimes too far from the submarines they were detecting. In the Pacific, therefore, an intermediate form of surveillance, HILAST, was developed about 1965. A P-3 flying at 20,000 ft monitored a square field of 9 LOFAR buoys spaced 75 nm apart; this combination was expected to detect any transiter at least once.

Longer effective ranges greatly increased the number of contacts with which the system had to deal. In 1968, in the Atlantic, SOSUS made 467,677 contacts, of which only 4755 were evaluated as submarines: 1716 U.S. nuclear, 2451 U.S. diesel, 303 Soviet nuclear, and 285 Soviet diesel.

By the early 1970s there was increased interest in using all-source intelligence, properly sanitized, to cue SOSUS arrays. The arrays achieved their maximum range in alerted searchlight mode because in that mode they could accept a higher theoretical false-alarm rate. In 1973 DoD issued a classified Area Coordinating Paper on Undersea Surveillance that seems to have shaped subsequent policy. The paper noted that SOSUS was

vulnerable to countermeasures and inflexible in its inability to deal with future very quiet submarines and third-party basing (i.e., basing out of Soviet base areas covered by the forward-area extension). The solutions were the following: better signal processing (including interarray correlation for lower overall system noise), which the 1973 paper suggested could deal with problems arising over the next 10–15 yr; possible alternative array concepts; and mobility (flexibility) based on towed arrays and deployable moored buoys. The towed-array solution was presumably encouraged by the success of the interim array (SQR-14) in the Mediterranean. The deployable buoys were the abortive RDSS (rapidly deployable surveillance system). The future possibilities were the fixed distributed system (FDS), which has actually been used; suspended arrays (as opposed to seabed arrays on the continental shelf, for deeper-water deployment); and coherent signal processing. As of about 1976, the improved signal-processing system was scheduled for operational evaluation in the winter of 1977–78.

◆ APS

Hardware characteristics of the McDonnell Douglas APS interactive TLAM planning system are as follows: 20–234 MIPS, 256 Mbytes of storage, 7.2 Gbytes on the hard disk within the equipment rack; 3D graphics, up to 1 million polygons/sec. The system is implemented on a Silicon Graphics 240GX workstation. The ashore version (TMPC Upgrade) has far more mass storage and higher performance (hence the range of speeds listed above). It uses a Loral ruggedized workstation.

The first APS engineering-development model (EDM) is scheduled for delivery in 1992. It was originally to have been aboard the *Wisconsin* but will now be on board the *Mount Whitney*.

◆ DSS

The DTC II-hosted data server system is the basis of the OSS (operational support system) that runs in the major fleet headquarters. During 1991 it was being installed in the OPNAV command center and in the headquarters of CINCLANT, CINCPAC, CINCLANTFLT, CINCPACFLT, and CINCUSNAVEUR (London and Naples). DSS runs JOTS II, Map Server, and Tactical Display Manager software, the Oracle relational data base management, and a series of tactical decision aids including CASES (capabilities assessment, simulation, and evaluation system) and FRESH (force requirements expert systems).

CASES analyzes combinations of different warfare areas and controls simulations and warfare models running simultaneously on other dedicated computers. Its models are Ray Mode Acoustic Propagation, Sweep Width/Search Rate Acoustic Search, ASW Barrier, ASW Area Search, IUSS (Integrated Undersea Surveillance System), OPTAMAS (Optimization of the Performance of Theater ASW Mobile Acoustic Sensors), Acoustic Detection, Battle-Group Defense, and Carrier- and Land-Based Air Strike. It also includes 2 expert systems, OPERA (ASW water management) and ASSESS (to derive conclusions from CASES studies, including generation of summary reports). OPERA bases its recommendations on the expected detection and attack potential and expected survivability of the various available ASW platforms (air, surface, submarine). CASES was developed under DARPA sponsorship (under the Strategic Computing Program) and is now operational at CINCPACFLT at Pearl Harbor. It is currently running on a Macintosh and has to be revised for DTC II operation.

FRESH is used for resource allocation (logistics) and provides daily information on force alert and readiness, fuel consumption, and personnel. It originally (1986) used a VAX to carry its large data base. FRESH is currently running at CINCPACFLT and NOSC San Diego.

◆ EWCM

EW coordination module, developed by NRL, is intended to allow force commanders to evaluate alternative EW tactics on a

large scale quickly enough for them to be implemented. Decision aids include selection of optimum power and frequency of communications equipment (to minimize the probability of intercept) and optimum decoy location. The prototype first went to sea on board the *Eisenhower* in October 1989. EWCM is now to be merged with the NOSC ECM (electronic combat module).

EWCM is currently a stand-alone system, but it is being rewritten as an applications program for JOTS II.

◆ ISPS

An ISPS assists a force planner by giving an M (friendly) vs. N (enemy) simulation using Monte Carlo techniques. It can maximize strike effectiveness by changing the force mix (e.g., Tomahawk-airplane combinations). An ISPS should task mission planning systems such as TAMPs and the Tomahawk planner (TMPCU or APS). General Dynamics displayed its ISPS package at the March 1991 U.S. Navy League show (running on a DTC II); presumably, McDonnell Douglas (which developed TAMPs and APS) is also a potential supplier. ISPS is also a force allocator, choosing among mission profiles.

◆ JOTS II (USQ-112A)/VIDS

Despite its nonstandard hardware, JOTS II has been assigned the AN-designation above. USQ-112 is JOTS I (DTC I version), deliveries of which began in 1984. JOTS II was operationally evaluated on board the *Independence* and *Jouett* in June 1990; more than 200 systems were then hurriedly produced to support Desert Shield. They included JOTS installations on board the Australian and Canadian ships in the Persian Gulf. As of early 1991, Japan was considering a version for its P-3 Orions. Rapid production was possible because JOTS II is little more than a standard commercial workstation running software that can easily be reproduced.

VIDS (visually integrated display system), introduced in 1988, is used by the Joint Chiefs of Staff and the U.S. Customs Service. VIDS's software is written in the C language (using the Unix operating system) rather than in Rocky Mountain Basic, as in JOTS I. VIDS adds tactical decision aids to JOTS I, which was conceived as a stand-alone mission-planning tool. VIDS was designed to run on a more powerful workstation suitable for multitasking, with windows.

JOTS II is essentially VIDS adapted to networking, with more tactical interfaces, distributed graphics (X-windows), and the Wizard X software "tool kit," by means of which the user can quickly assemble application programs. The basic program consists of 300,000 lines of code, and it can run on any Unix-based computer with 32 Mbytes of memory, a 500-Mbyte hard disk, and a speed of 7 MIPS or more. The associated bus is Ethernet (generally a fiber-optic bus in U.S. applications). DTC II is the usual host computer, but JOTS II can also run on some Hewlett-Packard machines and on Silicon Graphics and Sun workstations.

The JOTS software comprises an operator-machine interface and 4 main programs: a tactical data base manager (Tdbm), a geographic data base (The Chart), communications, and the Wizard X "tool kit." Tdbm fuses available information to form a correlated track data base. Typically, 1 workstation in a ship's system is designated master track keeper, and its changes are automatically passed around the shipboard network. The ship designated FOTC (force over-the-horizon track coordinator) passes its track data base to other ships of its battle group via OTCIXS. With several battle groups (and several different countries' ships) operating together, it becomes necessary to designate a theater-wide FOTC (super-FOTC). This minor enhancement was added late in 1990 and tested early in 1991. The Chart automatically plots Tdbm data for display, and it also provides such navigational graphics as projected tracks. The communications software configures the system to accept various external inputs, such as OTCIXS messages (primarily OTH-Gold format). The "tool kit" defines such features as buttons, scrolling windows, and pop-up menus, by means of which applications can easily be built.

Version 1.1 (February 1991) is to include the following tactical decision aids:

- ASW: barrier search, area search, ray trace, propagation loss
- ASUW: 2-track analysis, maneuvering board, closest point of approach (CPA), range/bearing table
- ASUW/ASW: moving-target statistical tracker (MTST) analysis, transit search
- AAW: CAP engagement
- EW: satellite vulnerability prediction, integrated radar environment prediction (IREPS)
- Weather: prediction using the GOES satellite

The Chart is to be revised to include terrain elevation and other features (to support amphibious operations) and also to support more projections (a total of 15).

Ultimately, enhanced versions of JOTS II are to be used by the Joint Chiefs of Staff as their main command/control tool, by the ASWOCs, and by the major fleet headquarters (OSS, operational support system).

The current software contractor is INRI (Inter-National Research Institute), which is trying to rewrite the system in ADA.

◆ Maritime Mission Support System

PRB Associates (which makes TEAMS) is developing this ASWOC equivalent for the Pakistani navy, to support that service's P-3C UPDATE 2.5 aircraft. It runs on a VAX computer and incorporates Link 11; it does not include a fast spectrum analyzer. The first such system is due for delivery to the U.S. Navy in August 1991 (for transfer to Pakistan under Foreign Military Sales).

◆ MDS

The Tomahawk Mission Display System is used for shipboard planning of Tomahawk and combined Tomahawk-TacAir attacks. An MDS can electronically sort the missions available (via DTD) to select a strike package. Analogous sorting by hand would be totally impracticable because each mission is so complex, and because so many missions are available to any force commander. The MDS can automatically retrieve and display TCI data (target data, route data, launch data, and TLAM route graphics); it can generate strike packages (multiple mission/target combinations and specific times on target); it can input TacAir routes manually; it can prepare a digital map with TLAM and TacAir routes overlaid; it can recall and display TCI target images; and it can display the AAW threat against which the missiles are likely to fly (which affects tactical aircraft routing). The MDS terminal automatically receives TCI updates (called Mission Folder Updates, MFUs) from the TMPC (Tomahawk Mission Planning Center) via its communications processor (the GFPC).

Typically, then, MDS inputs are the TCI updates received via OTCIXS or TADIXS, the TCI data base received in cartridge form from the TMPC, and TacAir routes. The MDS searches to display/print target, geographic area, launch area, and mission constraints. It produces displays and paper folders of TCI data and displays and paper charts of digitized map data with TLAM and TacAir routes overlaid, and it generates and receives on-line Opnotes.

TLAM command/control information for tailored strikes (such as those made repeatedly in the Gulf area) can be collected into a single Tomahawk strike package to support the preparation of an Operations Plan (OPPLAN).

The MDS was proposed as a concept demonstration program by the 12th Cruise Missile Steering Committee (6 October 1983) and approved by the CNO in 1984; it was described as a means of preparing automated mission folders. It became a rapid-prototyping fleet demonstration system. The first engineering-development models (EDMs) were installed on board several ships and at shore stations beginning in May 1987; they run on HP-9350 computers with Zenith 386 or HP displays. The XMDS/DMIF version was installed on board the *America* in May 1989; it is compatible with the TMPC Block Upgrade pro-

gram. It runs on the same hardware (but with a floppy disk drive for DOS file access), but the CPU is upgraded to HP-9370, and an HP high-resolution (1280 × 1024-pixel) color monitor is required. The system also contains a laser printer and a color copier.

The software, developed by Tiburon Systems, is an outgrowth of the MDF function of the shore-based MDDS (Mission Data Distribution System, see separate entry). The current version, X-MDS, adds X-Windows (multiple windows operating concurrently), as well as a security log-on, OPNOTE receive and transmit, Tomahawk strike planning, and compatibility with TMPCs to support the BGM-109D (bomblet) version of the missile. X-MDS was informally released in March 1989. It consists of 3 main software packages: XMDs (X-Windows applied to Tomahawk C2), a digital map interface (DMIF), and a Tomahawk Command Information data base-generation package (used by the Cruise Missile Support Agencies of the CINCs to produce MDS data base cartridges). A multisensor processor system (MSPS) is being developed to provide near-real-time threat correlation and display updates. Further developments will include decision aids for Tomahawk strike planning and on/off-line training aids.

◆ MDDS

The Tomahawk Mission Data Distribution System is the heart of the ashore Tomahawk Mission Planning System. MDDS prepares both the digital data that actually guide the missile and a data package (TCI, Tomahawk Command Information) that describes the mission and can be turned into a computer display or a paper mission folder. The display portion of the system, the Mission Display Function (MDF), ultimately became the MDS, described above.

Mission data are entered into a large (about 80-lb) transportable hard disk drive, the DTD (Data Transport Device), which must be moved physically to C2 nodes such as carriers and then off-loaded to Tomahawk shooters. The DTD is 1960s technology and is now to be downsized. A single DTD (ships carry several) will contain digital data for numerous missions. The mission planner on board the ship will use the MDS to select the appropriate missions from among those available.

The MDDS, then, produces mission DTDs, electronically updates mission data, prepares the corresponding TCIs, and is responsible for mission accountability (i.e., it provides a facility for reviewing just what missions have been designed). The TCIs are transmitted in data-cartridge form to the MDS for mission selection.

This process is broadly analogous to that originally used for Polaris targeting. It is necessary because the missiles' flight paths must be specified in enormous detail, far too much to have been generated on board ship until quite recently. Moreover, it is far too much to be transmitted electronically. Mission upgrades are typically transmitted directly to the shooters (the corresponding TCI upgrades go to the tactical commanders).

Nuclear Tomahawk missions require an additional degree of validation. Tiburon makes DCP, the Data Transport Device Certification Processor, which certifies that mission data satisfy nuclear safety requirements.

MDDS currently uses a Rolm 1666 and a Data General computer. The workstation is a DTC. The system is being upgraded to use a Silicon Graphics workstation compatible with that planned for the APS.

◆ MTST

The standard navy Maneuvering Target Statistical Tracker is a software package used for OTH tracking in the TWCS, CCS Mk 1 and 2, JOTS II (MTST variant), and ATW/Outlaw Hunter/OASIS. The basic algorithm, developed by Tiburon Systems, has been written in Fortran, Turbo-Pascal, and ADA for various applications. It can run on a standard 80386 desktop computer. MTST processes contact and line-of-bearing reports and statistically projects ahead target position and area of uncertainty for any requested time. This is the basis for Tomahawk targeting.

Since Tomahawk is relatively slow, it arrives long after the initial target position report (e.g., as much as half an hour after firing). Without any statistical estimation of target position, all that can be said is that the target is somewhere within a circle whose radius is defined by the target's maximum speed. A much better estimate can be made using a series of earlier target positions and some knowledge of what the target is likely to be doing. The missile is not updated in flight, so it cannot make use of later data. If it were merely fired at the reported target position, the missile would spend considerable time searching, quite possibly within range of target defenses. It may also acquire and attack ships other than the target of interest since they may come closer to the original target position. The simplest solution would be to track the target continuously using some dedicated sensor, such as a space-based radar. However, the central U.S. decision was to avoid exactly that solution, on the ground that it would be costly and inflexible. Instead, Tomahawk antiship targeting relies on data from a large number of dissimilar sensors, most of which were never intended for this specific purpose.

Hence MTST, which was developed by those who originally developed Outlaw Shark. See also ATW.

◆ Outlaw Hunter/OASIS

Outlaw Hunter was conceived as a means of binding the P-3 with its ISAR radar into the overall fleet OTH-T system. It applied accurate target-location data and an area of uncertainty to the target identified by the ISAR imaging radar. Aircraft position was obtained from GPS, and the data thus developed were correlated with the JOTS data base (received via OTCIXS) and then transmitted to other platforms (e.g., those using the Tomahawk Weapons Control System, TWCS) via the OTCIXS link (OTH-T Gold message format).

The new ISAR radar made the P-3 effective (for target identification) against Soviet warships equipped with long-range defensive missiles, particularly SAN-6. The problem was that their inertial navigation systems (2 LTN-72s) were not accurate enough to fix those targets within Tomahawk launch criteria (the missile cannot be allowed to spend much time searching for its target at low speed within the target's self-defense zone; position errors translate into search time). The solution was to use the new GPS navigational satellite system. In Outlaw Hunter, GPS data are assigned a figure of merit for purposes of comparison with inertial navigation fix data; the inertial navigation system takes over when the figure of merit falls below a fixed value. The radar and the navigator are combined with a communications system that can pass targeting information to a Tomahawk platform with the necessary speed and reliability (via OTCIXS).

The fallback to the inertial navigator is necessary because the GPS satellite constellation is still incomplete (ultimately, an airplane receiving 4 satellites will be able to fix its position within 75 ft). For example, as of early 1991, gaps in full coverage in the Eastern Pacific amount to 12–16 hr/day, and in the Western Pacific they amount to 8 hr/day.

The on-board data processor is the Tiburon ATW (see separate entry, below). As used in Outlaw Hunter, the ATW can display tracks, labels, and areas of uncertainty. The workstation can also play back or fast forward the tracks it carries, so the operator can analyze target motion and detect trends to predict future actions. The operator can list displayed tracks, read incoming Opnotes, create outgoing Opnotes, control the list of addressees, view the incoming-message log, and select output filters. The operator can designate an area from which all of the updated positions for the contacts, which are being automatically tracked by the aircraft's ISAR radar, can be transmitted either manually or automatically at set intervals. This feature is valuable because it provides a distant commander with a full picture of all shipping in an area, besides the target of interest. Opnotes can indicate the confidence of the ISAR operator in target classification, and they can also send environmental data

such as wind speed, direction, and air temperature, all of which are important in Tomahawk launch planning.

The system was first installed on board a VP-9 P-3C in August 1989, and about a year later this airplane was turned over to VP-19 at Misawa. In tests in 1989-90, tracks or Opnotes transmitted via OTCIXS to ships or to shore sites typically took about 3 min from transmission to verification of receipt. To reach a submarine, data must be routed through a Shore Targeting Terminal (STT), which imposes a 5-8-min delay. In the 1989 exercises, Outlaw Hawk successfully cued the submarines *Salt Lake City* and *Omaha*. The system was also used to provide targeting and prestrike surface pictures to a carrier, both to the combined strike warfare commander (Alfa Sierra) and to the aircraft themselves (via voice SURPICS [secure voice]). Outlaw Hunter has also transmitted targeting data over Link 11 and over plain-voice channels, sometimes simultaneously with the OTCIXS and SURPICS channels.

On board the Orion, a single equipment rack, just aft of the sonobuoy storage rack, accommodates a communications/radar processor (CARP), a generic front-end communications processor (GFCP), a satellite communications controller (ON-143(V)6) with an encrypting unit (KG-84), and the modem and other equipment linking the communications processor to a small satellite antenna (DMC-34) atop the airplane amidships. A second antenna serves GPS. The ATW itself is just forward of the aft observer's station. Besides its high-resolution display, it has a laptop computer to monitor overall hardware performance and to display raw teletype information.

The Outlaw Hunter P-3C proved very successful in Desert Shield; presumably, it supported maritime interdiction (the embargo) by detecting, identifying, and tracking the very numerous merchant ships in the area around Iraq.

OASIS (OTH-T Airborne Sensor Information System) is the successor to the 1989 Outlaw Hunter prototype system. OASIS I was assembled quickly to equip an Atlantic Fleet P-3 for Desert Shield. It is Outlaw Hunter with more reliable components and upgraded tactical software. In this version, the OTCIXS channel is the satellite communications system designed for UPDATE IV. The tactical data processor uses a VME system bus to connect the CARP (which receives both GPS and ISAR radar data) with the ATW and also with a scan converter. The scan converter provides ATW video output to a channel selector, which the TACCO can use to display ATW outputs or APS-137 radar video or data from the aircraft's mission computer (CP-901); thus, the main system display has moved to the TACCO station, where it belongs. The TACCO controls the system via trackball and keyboard.

OASIS II is a repackaged (230 vice 550 kg, smaller volume) Outlaw Hunter occupying 2 racks at the ordnanceman's station of the P-3C. The correlator uses 80486 chips. At present, OASIS II can use its ELINT correlator to cue the ISAR radar operator, and it can project ahead radar tracks to regain false contacts. The combination of active radar and correlated passive (ELINT) data makes an OASIS airplane a source of independent, fully correlated OTH-T data; alternatively, it can feed a larger network of FOTCs. Current plans call for installations on board P-3Cs (possibly as part of UPDATE IV) and probably 3 S-3s (during 1991). OASIS is later to be extended to use ALR-66 inputs and satellite data.

See also the separate entry for the ATW workstation used in Outlaw Hunter.

◆ POST

POST (Prototype Ocean Surveillance Terminal) accepts and automatically processes, correlates, and displays data from a wide variety of sensors. Correlation is by a statistical/heuristic algorithm using such factors as radar emissions (for identification), feasibility of different possible motions between detections, and likelihood of movements. For example, 2 detections of a ship's air-search radar 30 nm and 15 min apart would have to be taken as separate ships, whereas the system might determine that 2 such detections 30 nm and 70 min apart came from

the same ship. The result of correlation is a picture of the likely positions of ships, a data base that can be used, e.g., for OTH-T.

POST is thus the expression of the U.S. decision to try to fuse data from the great variety of existing sensors, many of them national, rather than develop a single dedicated ship-detection and -tracking system (which would not need much in the way of data-fusion capability).

As its name implies, POST was conceived as a hardware unit but ended up as software running on the standard DTC II computer.

◆ TAMPS

McDonnell Douglas's Tactical Aircraft Mission Planning System is the standard aircraft planning system for the U.S. Navy and Marine Corps, developed in 1985. The first delivery was for the *Carl Vinson* in August 1986. As of March 1991, McDonnell Douglas offered a modified version to foreign customers. At this time TAMPS is installed on board 11 carriers and at numerous land sites. A further development (a rapid advanced prototype system) was produced in 1989-90.

◆ TEAMS (TSQ-142)

The Tactical EA-6B Mission Support system provides an EA-6B squadron either on board a carrier or ashore with full mission data (as assembled from the vast amount of intelligence available before flight), and assimilates data collected in flight. TEAMS is unusual in that it actually reprograms 3 sets of EA-6B mission computers (navigation, ALQ-99, and HARM) on board the airplane by means of a data cartridge inserted at flight time. TEAMS also produces flight plans, kneeboard charts, and 30-min strip maps. One cartridge can carry several missions' worth of data, so a mission can be changed even after the EA-6B has taken off. In flight, the airplane's ECM receivers feed their data into the cartridge, whose contents are read back into the TEAMS data base after the EA-6B lands. To serve the new ADVCAP version of the EA-6B, TEAMS will program a total of 9 aircraft computers (including ALR-67ASR, ALQ-149, and the ALE-47 chaff launcher). TEAMS's data bases include the Defense Mapping Agency's computerized maps (including terrain) and several intelligence data bases; the system receives tactical intelligence (TENCAP) data directly via OTCIXS nets. TEAMS also includes performance predictions for the airplane, for its ALQ-99 system and for the HARM missile, so it can predict the effect of a particular mission profile or tactic in a specific situation. On a carrier, it runs on paired VAX 3800 workstations (each with 32 Mbytes of RAM and about 2 Gbytes of storage). There is also a transportable version for the Marine Corps, and a portable version is currently under contract. The system is being developed into an open architecture that will be suitable to a variety of workstations, such as Sun (DTC II series) or the new IBM RISC stations.

TEAMS was developed by PRB Associates. It entered service in 1984 and at the time was probably the first such mission planner to program the airplane for a particular mission (by reprogramming its computer). The current version carries a data base covering 6-7 million square miles, with very large lists of friendly and enemy orders of battle. It keeps track of these orders of battle and also of theater assets (such as weapons and expendables). The post-flight readouts are used both to update the data bases and to reconstruct missions to extract lessons learned and tactically significant intelligence and EW data; the system helps produce post-action messages and reports.

A TEAMS derivative is now being developed to support EW reprogramming for radar-warning receivers and jammers on board other carrier-battle-group aircraft.

◆ TIPS

TIPS (tactical information processing system) is the current tactical/administrative system on board LHAs and LHDs. It uses a single UYK-7 (LHA) or UYK-44 (LHD).

◆ TMPS/TMPCU

McDonnell Douglas's Tomahawk Mission Planning System was developed in 1978 and is now deployed in 9 locations worldwide. This is a shore system to develop attack flight plans for land-attack Tomahawks. Mission tapes must be physically brought aboard attack platforms (the amount of data is too great for radio transmission). The new APS is to provide this capability aboard ships.

TMPCU, the Tomahawk Mission Planning Center Upgrade (both ashore and afloat), was first delivered in 1988.

Tomahawk missions represented by TMPS tapes are displayed aboard carriers using a Tiburon Systems Mission Display System (MDS). MDS will also be used to display the output of the APS. It currently runs on a DTC I computer and is being rewritten for DTC II.

◆ TMS/ATMS

Track Management System was developed by Lockheed Missiles & Space Company under a DARPA contract as part of the company's Advanced Navy Battle Management (ANBM) program. TMS, which was tested on board the *Vinson* and *Belknap*, was the first U.S. Navy Unix-based, Sun workstation, command/control system and the first to use windowing. It is probably the *Vinson* experimental system (SDMS) described under JOTS in the main text. TMS provided tracking and decision-making algorithms to complement display and communications-management functions from JOTS. TMS, which is written in C and Fortran, is now being rewritten as JOTS II applications software.

TMS uses the position-fixing algorithm written for the Tomahawk Weapon Control System (TWCS) Block II, extended to add acoustic correlation data. Inputs are OTH-T Gold, Rainform, JINTACCS, Link 11, and Link 14 messages. TMS filters contacts by category, threat class, area of interest, and ELINT category of interest (i.e., identity category). It can develop target positions and tracks based on single or multiple hypotheses. The system incorporates 3 major data bases: contacts (50,000 per 100 Mbytes of disk storage), tracks (more than 10,000, each with attributes such as emitter characteristics, and a list of up to 100 contacts), and a technical library.

ATMS, the ASW Track Management System, is a Lockheed private-venture development of TMS. It and an associated oceanographic package (Nautilus) have been developed as part of Lockheed's bid for the Surveillance Direction System (SDS). Lockheed is associated with Raytheon (Submarine Signal Division), SAIC, and Planning System Inc. (PSI) in its SDS bid.

◆ TWCS

TWCS (Tomahawk Weapon Control System) is SWG-2 (ships with armored box launchers)/SWG-3 (ships with vertical launchers). It consists of a track-control group (TCG) and a launch-control group (LCG). The TCG receives target information from own-ship, battle group, and external systems via data links and maintains a surface-track data base over the launching ship's area of responsibility; the data base in turn is used to develop missile-engagement plans. The LCG maintains a missile inventory (monitoring numbers and types), selects and programs missiles, and monitors launching. SWG-2 was evaluated and then brought into service in 1984. The current upgrade replaces the original UYK-19 computer with the more capable UYK-64. It also incorporates the capability to program and control the RGM-109D (bomblet) version of the missile. Further upgrades allow more flexible targeting, incorporate tactical decision aids, and accept more external data, such as that derived from electronic intelligence. The SWGs are designed primarily to support antiship attack. The overland flight of land-attack Tomahawks is currently planned ashore (hence the importance of the APS) at a theater mission-planning center (TMPC); flight plans are provided to ships in the form of data-transfer devices (DTDs).

◆ USQ-64

USQ-64 is the special tactical intelligence link, using FLTSATCOM, that exchanges data among systems such as Outboard and Combat DF. A single net can carry up to 23 subscribers.

◆ USQ-83

At the end of December 1990 GTE was awarded a full-scale production contract for the new USQ-83 data terminal set, to be delivered in 1992. USQ-83 replaces not only the current USQ-74 Link 11 data terminal but also the current HF fleet broadcast terminal (UCC-1) and the advanced narrow-band digital voice terminal (ANDVT). Work on USQ-83 began in 1985, and the first 4 production units were delivered for tests in 1989.

◆ Link 14

A plan to replace all Link 14 terminals with receive-only Link 11 was canceled early in 1990. A stand-alone, 2-way Link 11 proved less expensive. The latter uses a Link Eleven Display System, part of which is USQ-69.

◆ Copernicus

Copernicus is the new U.S. fleet-level command and control architecture, using very powerful workstation terminals derived from the JOTS program. The object is to reorient naval communications so that the communications links revolve around the users rather than the other way around. Hence the name. In this system, the total available communications capacity is split by software into the required set of satellite links (GLOBIXS and TADIXS). The links are virtual, i.e., software-defined, rather than hardware-defined, and their boundaries (capacities) can shift to accord with tactical needs. The lesson drawn from JOTS is that by using commercial or commercial-type hardware, the system can be built up very rapidly, its developers concentrating on creating the required software.

Copernicus is currently described as the navy's C4I (command/control/communications/computer/intelligence) post-Cold War architecture, with special emphasis on the ability to shift focus among geographical areas. That is possible because it relies on space-based rather than fixed surface assets.

The responsible OPNAV agency is OP-094 (space and electronic warfare, or SEW). Without SEW, the battle space of a carrier battle group is about 500 nm in radius. With SEW added, the radius increases about tenfold. Here SEW includes both space-based surveillance and passive (ESM as part of EW) surveillance beyond the battle group horizon. Effective use of ESM data requires data fusion on a very large scale, ultimately on a global scale. The OP-094 view goes so far as to suggest that the composite warfare commander (CWC) of a battle group should add a composite SEW commander to the traditional quartet of AAWC, ASUWC (antisurface), STWC (strike), and ASWC.

Copernicus, then, is the latest attempt to solve the problem of effectively using nonorganic sensors. Such sensors, and OTH weapons, first appeared in the 1960s, together with the earliest satellite communications that would ultimately tie them all together. The nonorganic sensors (largely ESM/ELINT) matured in the 1970s, when UHF (i.e., high capacity) communications satellites appeared. In the 1980s the introduction of Tomahawk antiship missiles made it vital to find some means of doing OTH-T; the U.S. choice was to do so by data fusion rather than by introducing some new dedicated system. Multifrequency satellite communications and C4I should mark the 1990s.

The new architecture must merge organic and offboard sensor data, providing the same picture to all commanders, ashore and afloat. In the past, the issue has been whether to concentrate command in a flagship afloat or in a center ashore with better access to data (particularly from "national" sources such as satellites). The choice in Copernicus is "distributive fusion," in which information is freely passed through a network, and each node in the network contributes to the same overall tactical picture. This is much the same idea as a fully distributed combat system but on a much larger scale. Just as the distributed

combat system is practicable only because shipboard data buses now have sufficient capacity, distributive fusion is possible only because the satellite links now have enormous capacity. In the past, too, the communications system was easily overloaded because channels could not interchange capacity and, thus, there was very limited surge capacity in a crisis. Moreover, most messages were of the wrong type (narrative) and had to be produced on paper. In addition, in the past much ESM data has been so closely held that commanders have not realized just how valuable such assets could be.

The messages themselves are of little moment. What matters is the fused tactical picture built out of them. To produce that picture, the messages have to be recast into a computer-to-computer, essentially graphic, form.

Copernicus is to use a special intelligent terminal, FASTT (Fleet All-Source Tactical Terminal), to streamline the mass of special messages currently in use and also to sanitize them. For example, an OTH-T message (which would contain information limited to special U.S. users) could be searched to eliminate information limited to NATO users in the Mediterranean. It can also be reformatted to eliminate references to specially classified U.S. sensors, and specially sensitive information can automatically be removed. This sort of reformatting is necessary if messages are to be used directly to build the data bases (i.e., tactical pictures) in numerous locations.

Beyond the communication server (FASTT), there are 3 other main computer building blocks: a desktop series (equivalent to personal computers, not to the DTCs), a tactical workstation series (TAC III), and file servers to handle large data bases. One objective of the system is to develop a common (across warfare areas) method of handling and denoting tracks. One reason is that the warfare areas are not really altogether separate: for example, a submarine (ASW) can and often will fire antiship missiles (AAW).

The Copernicus project office was established on 1 October 1990, and the first industrial symposium held to announce system architecture was held on 28 January 1991. As of that time, the Copernicus hardware and software program, leading to a 6-yr procurement plan, was to have been completed during 1991.

◆ GLOBIXS and TADIXS

New high-capacity command links (GLOBIXS and TADIXS) have been developed since 1985 to work with FCC ashore and TFCC at sea. TADIXS will replace the current OTCIXS. The new system replaces a current series of formatted OTC messages, each of which requires its own dedicated communication net. Because each formatted net is concerned with only one type of sensor, this system does not encourage consolidation of sensor data. The specific combination represented by the OTCIXS nets reflects the requirements of war against the Soviets. The many separate nets also exhaust finite UHF communication capacity. The new philosophy, of which JOTS is a part, is to structure the nets functionally rather than by data source. All subscribers to the tactical nets have access to the tactical data, which they may need to be able to operate in large (over-the-horizon) battle spaces. The new official view is that it is literally easier for all tactical subscribers to have full access than to choose which data each subscriber really needs. Subscribers filter data themselves, e.g., geographically.

This type of exchange requires that data from numerous sources be concentrated ashore for transmission by functional channels; the ashore centers (the FCCs) communicate among themselves and receive data via the GLOBIXS net. The TADIXS net operates in both directions so that commanders afloat can fuse FCC-provided data with their own data and then send the results back for comparison. The afloat terminals of the system are the TFCCs and the JOTS terminals.

GLOBIXS data are transmitted over the Defense Data Network (DDN) and the Defense Satellite Communications System (DSCS). The GLOBIXS constitute a data network among the FCCs (with input from some other sources, such as the DoD

and naval intelligence systems). Some of the GLOBIXS nets will cross connect. FCCs ashore take GLOBIXS data and consolidate them into TADIXS broadcasts to the TFCCs afloat.

The TADIXS/GLOBIXS combination is intended to replace a current system, based on Naval Communications Area Master Stations (NavCAMs), with one controlled more directly by the FCCs and TFCCs. The current fleet broadcast mixes operational and administrative signals, which are difficult to disentangle and which fill a limited jam-resistant channel capacity (sixteen 75-baud channels). The choice in TADIXS is to split up the broadcast, relegating administrative signals to the NAVIXS channel. The different TADIXS channels compete with one another for channel space, which will ultimately be allocated among the EHF, SHF, UHF, and HF satellite capacity.

Current satellite capacity limits are:

Comsat	1.544 Mbits/sec
EHF	2.4 kbits/sec
SHF	19.2 kbits/sec
UHF	9.6 kbits/sec
HF	1.2 kbits/sec

As an example of communication-load requirements, each tactical report (HIT) of the current type consists of 10 lines (65 characters, each 8 bits), or 5.2 kbits. In a typical 18-hr period, a carrier battle group in the Mediterranean might receive 500 such reports (2.6 Mbits) coming from a series of organic and nonorganic sensors. These reports would include indications and warning, queuing, tracking, targeting, engagement, BDA, and retargeting. Current message capacity in the Mediterranean, in terms of retransmission from the major shore stations, for the battle group is 155.5 Mbits/18 hr, so the overall system has sufficient link capacity (i.e., satellites and radios) if that capacity is properly used, i.e., if it can be spread across channels. However, the capacity is currently spread among several channels.

Global Information Exchange Systems (GLOBIXS):

GLOBIXS A	SIGINT Management
GLOBIXS B	ASW Management
GLOBIXS C	SEW Management
GLOBIXS D	Command
GLOBIXS E	Imagery Management
GLOBIXS F	Data Base Management
GLOBIXS G	RDT&E Coordination (new secure telephone net)
GLOBIXS H	Navy-wide Administration

Tactical Data Exchange Systems (TADIXS):

TADIXS A	OTC Battle Management
TADIXS B	ELINT
TADIXS C	SEW Management
TADIXS D	ASW Management
TADIXS E	AAW (JTIDS)
TADIXS F	Tacintel (Tactical Intelligence)
TADIXS G	Cruise Missile Targeting
TADIXS H	High Command
TADIXS I	INTELCAST (Intelligence Broadcast)
TADIXS J	NAVIXS
TADIXS K	Common High-Band Data Link
TADIXS L	INTELNET (Intelligence Net)
TADIXS M	Combined Broadcast
TADIXS N	Single Integrated Satellite BCAST (Broadcast)

Here SEW is space and electronic warfare, a term that replaces radio-electronic battle management and expresses the key role of space assets in intelligence and battle management.

◆ Cardion MCDS

Modular Combat Display System is a new small-combatant CDS announced at the 1990 U.S. Navy League show. It had already been in production for some time for a friendly navy. MCDS is based on the video processors Cardion developed for SPA-25G and SPA-50G; as the main text suggests, the gap between such displays and a full-fledged CDS is narrow indeed. A

full MCDS would use a 1553B bus to carry sensor data, which would be picked off by a series of operator consoles and a horizontal command console. The latter is the only real new display unit; it is a 23-in monochrome (20-in-diameter viewable area). It is viewed by 3 operators, each of whom has a keyboard and trackball. The system can accept radar scan rates of up to 60 rpm and pulse widths of 0.06–600 microsec. Each console can handle up to 6 radar inputs plus 2 TV inputs (TV and IR).

The brochure concentrates on the details of the consoles. The operator console contains a microprocessor that feeds both a video processor and a graphics processor (3 or 4 memory planes, 8 or 16 colors/region, allowing for write-protect areas). The sensor video processor provides 3–5 memory planes (i.e., it can display 3–5 sensor pictures simultaneously), up to 16 radar gray shades, and up to 32 TV video levels. It can control the apparent decay of radar traces. The display for both is a high-resolution, raster-scan, 19-in color or 23-in monochrome monitor (1365 × 1024 pixels). Frame rate is 60/30 frames/sec (80/40 is also available). The radar picture can be offset, and the system carries 256 programmable symbols. There are 8 range settings (2.5–320 nm). The console processors are dual 68000-based units, and the console processor's memory is 32 kwords of 16-bit RAM plus 32 kwords of 16-bit EPROM.

The command display is 1024 × 1024 pixels; the vertical line frequency is 60 Hz (interlaced).

The system can also incorporate separate applications processors, e.g., a sonar signal processor. As described by Cardion, it does not include weapons control directly, although clearly that can be accomplished through the system bus (MCDS is described as a means of compiling and maintaining a full current tactical picture). For example, the typical screen layout shown in the brochure includes weapons' firing status ("ready to fire") and other engagement data alongside a synthetic-video PPI picture. In the project already underway, Cardion is a subcontractor to the system integrator, which provides the weapons-control console(s).

◆ Raytheon ICS

Raytheon announced a new Integrated Combat System at the March 1991 U.S. Navy League show. The company hopes to use the CDS design and integration expertise built up during the NAAWS effort to develop and sell core systems of its own. Its work includes the track management and TEWA software required for combat direction, and also a series of new consoles that can be adapted to an advanced bus to form a distributed and reconfigurable combat system. The question then will be which element, the core or the missile, is the limiting factor in overall system reaction time or defensive capability. At present the kinematics of the Sea Sparrow missile limit existing systems much more than their core architecture. The solution would be to use the tail-controlled version with a new motor. Once the missile is fixed, then it becomes more important to provide the new core.

ICS is a fully distributed combat system using a pair of buses (port and starboard) that communicate with sensors, weapons, and support systems via a series of system interface subsystems (SIUs). The command and display subsystem will have 4–10 consoles, 1–2 plotters, and 1–2 hard-copy terminals. Processing will be done by a series of computers tied to the same bus, with 2 mass storage units and 1–2 tape units. The baseline system processor is a MIPS RISC machine running a POSIX-compliant operating system and incorporating a VME-type backplane. It can be upgraded to the next-generation Futurebus+ backplane. Each multifunction display console carries 1 or 2 screens and a single keyboard; it is driven by a MIPS R2000 display processor. The displays are militarized versions of the Silicon Graphics (SGI) Personal IRIS workstations and, thus, are related to the CCS Mk 2 consoles that Raytheon has already developed for submarine use. The system bus is either Ethernet or the fiber-optic standard (FDDI) in its militarized form (Safenet II).

At this writing Raytheon was still competing with GE for the Taiwanese frigate project (now for the 8th rather than the 7th

unit). Raytheon's CMAR competes with GE's ADAR-N; a preliminary decision was expected in the summer of 1991. Even though only a single frigate is involved, the winner will have a good chance of being selected for the corvettes to follow.

◆ ATW

Tiburon Systems's Advanced Tactical Workstation incorporates a dedicated correlation "engine." It is used in several OTH-T systems, including Outlaw Hunter and its successor, OASIS. ATW uses the navy-standard Maneuvering Target Statistical Tracker (MTST), combined with ELINT and attribute correlation, to associate reports with tracks and also to associate dissimilar tracks. The ATW software runs on a standard AT-compatible personal computer (such as a CP-1933/UYK) with a high-resolution color (VGA) monitor driven by an 80386 chip (with an 80387 coprocessor), with 4–16 Mbytes of RAM, a Video 7 VRAM graphics card (with 512 kbytes of RAM), a hard disk with at least 40 Mbytes of storage, and a Microsoft mouse or trackball. The current software is written in Turbo Pascal, and a translation into ADA is under evaluation. It is also being modified to work with the X-Windows graphics package used in JOTS and JOTS-related systems.

The ATW executive system controls 5 program packages: Communications Processing (data reception from OTH Gold, TACELINT, Bullseye [HF/DF], ATARF, ISAR), Correlation Processing, Track-File Management, Tracker Processing, and Tactical-Display Processing. The correlation processor correlates received track numbers, unique attributes, ELINT data, hull-to-emitter data, and TIB files and associates tracks. The track-file manager updates, deletes, merges, disassociates, and reprocesses tracks, and conducts periodic track maintenance. The tracker processor updates track parameters, generates track solutions, and assesses whether the generated positions are in fact feasible (i.e., whether a ship of known capabilities can get from a past known position to a projected position in the time available). The display processor includes tactical decision aids.

Here ATARF is Automated Tracking and Reporting Format, a message format used with IUSS messages. TIB is the Tactical Information Broadcast, a U.S. Air Force intelligence broadcast associated with the RC-135 (Rivet Joint) program. OTH Gold is the message format, formerly JINTACCS, used by a battle group's FOTC; it is a machine-readable format that gives a ship's name, location, and time. This is the format read by JOTS.

The major advantage claimed for ATW is that its data base is flexible enough to handle a wide variety of data, from both on-board and external sensors. It can form multisource track files, support bearings-only tracking, and allow track merging and unmerging (when a track merge proves erroneous). It can also generate free-text TACNOTES to provide a distant commander with some feeling for the confidence in which track or location data are held. ATW supports both FOTC participant and non-participant modes of operation. ATW also logs incoming and outgoing messages.

ATW is both similar to and competitive with many aspects of JOTS. See also Outlaw Hunter/OASIS above.

The connection with Outlaw Hawk/Outlaw Shark is not coincidental: Jere Patterson, the founder and president of Tiburon, managed both programs while at Lockheed Missiles and Space Company (Tiburon, Spanish for Shark, recalls the earlier association).

◆ DGU

DRS's Display Generator Unit is for the IPADS upgrade proposed for Naval Reserve P-3As and -3Bs. DGU feeds a high-resolution (1664 × 1024-pixel), monochrome, raster-scan display and can handle graphics processing as well as tactical and acoustic displays. The DGU hardware also supports windows (960 can be formed to display waterfalls and multiple I/O pairs). The video output provides 6 planes of memory (including alphanumeric and cursor planes), 8 or 16 shades of gray, and a graphics overlay. Display formats are fully programmable.

DGU uses 68000-series processors, with dual parallel, bi-directional SCSI buses and 2 RS-343 outputs. It has high-speed memory and acoustic-data storage for 16 channels of LOFAR, 16 of ALI (automatic line integration), 16 of BVF, 2 of active, 4 of Beta band, and 2 of BT (bathymograph). Display formats are ALI, LOFAR, BVF, DICASS, Beta Band, and BT.

◆ DTC II

The total DTC II contract is for 3000 computers (total cost \$115 million), of which more than 1800 had been delivered by the beginning of 1991. There are currently several alternatives based on different Sun workstations: Sun 4/110 (7.5 MIPS), Sun 4/300 (16 MIPS), and Sun 4/470 (22 MIPS—may be used for the NIPS program; it is a powerful file server, with up to 6 Gbytes of storage). These machines can also accept special graphics and applications processors on internal boards, e.g., the CSPI Supercard 2 array processor (a 6U VME board using the 40-MHz i860 RISC microprocessor, with total throughput of 80 MFLOPS) used in the SURTASS and LFA programs.

At least partly because of cost, DTC II (\$80,000) superseded the Raytheon CWS (\$250,000). However, there were also claims that CWS was not ready in time for the initial deployment of FDDS on board the *Saratoga* in 1989.

◆ DTC III (TAC III)

DTC III has been renamed TAC (Tactical Advanced Computer) III. As of March 1991, the TAC III RFP had not yet been issued.

◆ FASTT

The Fleet All-Source Tactical Terminal is a basic element of the new Copernicus architecture (see above). TRW displayed its version, which it called FAST (Fleet All-Source Terminal), at the March 1991 U.S. Navy League show, but it gave few details. The only statistic given was that FAST could perform high-speed character matching at up to 9.5 million characters/sec.

◆ GFCP

Tiburon's VME-based, generic front-end, communications processor is currently deployed on board ships and at shore stations to support Tomahawk targeting. It is an interface between tactical data processors or a Tomahawk mission display system (MDS) and the ON-143(V)6 satellite interface used for the OTCIXS net during Tomahawk targeting; for example, GFCP is part of Outlaw Hunter/OASIS. It formats and reformats messages, determines and controls data routing to appropriate systems, allows tactical data processors and communications systems with different interface protocols to exchange data, and provides message buffering. Applicable tactical data processors are the USQ-81(V) OTH-T system (formerly Outlaw Shark/Outlaw Hawk), JOTS, the Fleet Data Distribution System (FDDS), the Tomahawk command/control network (CCN), the Tomahawk Mission Data Distribution System (MDDS 1.X and 2.X), the Tomahawk Mission Display System (MDS), TWCS, and OSIS baseline and upgrades (OBS/OBU). Planned applications are to TEPEE, VIDS (visually integrated display system), and TAMPSS.

◆ OJ-663/UYQ-21

This is the latest UYQ-21-series console. The prototype exists, and the console was already under contract as of late March 1991. It carries a touch pad, a keyboard, and a trackball. The console carries a 19-in color monitor (1280 × 1024 pixels). This console uses X-windows software with real-time tactical extensions (e.g., it can show real-time radar video and NTDS synthetic video simultaneously).

◆ UYQ-31

Raytheon's standard polar situation displays are used in the SLQ-32 and SQS-56 systems. UYQ-31 is a modular device that can fit through a standard submarine (25-in) hatchway when its keyboard shelf is removed. It is an intelligent programmable

console that can be used either with a host computer or on a stand-alone basis, and it can also be backfitted to existing devices. The 15-in raster-scan CRT (1024 × 1024 pixels) has a 50-Hz refresh rate and is fed via a programmable display processor. Operator controls are a keyboard and a stiff stick.

◆ ASQ-212

This is the designation of the UNISYS computer system now replacing ASQ-114 in the P-3C UPDATE III, incorporating a CP-901A computer in place of the earlier CP-901. At the March 1991 U.S. Navy League show, UNISYS distributed a brochure on its proposed airborne ASW open architecture, which will use the next-generation computer and will presumably be offered to the navy in the event that the Boeing UPDATE IV is abandoned.

◆ UYK-83A

C3 Inc.'s ruggedized 80386-based PC.

◆ UYK-85A

C3 Inc.'s ruggedized 80486-based PC.

◆ ASPRO-VME

In 1991 Loral announced a version of ASPRO suitable for mounting within a larger 6U VME-backplane computer. The upgradable family of parallel processors offers from 150 MFLOPS (with 512 processing elements) to 2.4 GFLOPS (8192 processing elements). The basic processor resides on 3 boards (1 array memory with 512 processing elements, 1 array control, and 1 control processor). The control processor is a MIPS R3000. Each custom VLSI processor chip contains 32 processing elements; each element contains a high-speed, word-parallel arithmetic unit and a bit-serial logic unit. The associated scalar processor is a MIPS R3000/R3010 RISC processor. Memory is 128 kbits/processing element (8 Mbytes/array memory board) expandable to 1 Mbit/element. Scalar memory is 2 Mbytes on the control processor board, expandable to 32 Mbytes. Array memory to processing element sustained transfer rate is 640 Mbytes/sec (512 processing elements) to 10.2 Gbytes/sec (8192 processing elements).

STRATEGIC WARFARE

USSR

◆ SS-N-23

The Soviet designation for SS-N-23 is RSM-24.

UNITED KINGDOM

The British WE 177, which is the only current British free-fall nuclear weapon, entered RAF service in 1966 and RN service in 1971.

UNITED STATES

The FY92/93 program (announced in February 1991) calls for the following purchases (FY92 unit cost is given):

	FY91	FY92	FY93	Unit cost
Trident D-5	52	28	31	\$39.3 million
Tomahawk	400	236	200	\$ 1.92 million

The FY91 *Ohio*-class submarine (the 18th) is to be the last. The first 10 *Ohio*-class submarines are not to be reequipped with Trident-II missiles. Of earlier strategic submarines still in service, 4 are to be retired during FY92 and 6 during FY93. Thus Poseidon C-4 should be out of service by the end of FY93.

◆ Tomahawk

As used in the Gulf War (January 1991), Tomahawk was reportedly extremely successful, 51 of the first 52 fired hitting their targets. Hits included several within Baghdad, including 1 that clipped a television tower in half. Reportedly, about 100

Tomahawks were fired as precursors to the manned air strike on the first night of the war.

Reportedly, the chief limitation in Tomahawk's operation is the cumbersome mission planning, including the difficulty of estimating the missile's time of arrival over a target. See the APS (Afloat Planning System) entry in the Surveillance and Control section.

The FY91 supplemental program includes an additional 400 Tomahawks, and early in 1991 the production of missiles ordered in FY89 was accelerated. About 300 Tomahawks were fired during the war with Iraq. It was reported that at the outbreak of war on 16 January the total inventory of land-attack conventional Tomahawks was about 900 BGM-109Cs and 100 BGM-109Ds (bomblet version). By mid-February missiles had been fired by both of the battleships in the area (*Missouri* and *Wisconsin*), by 11 other surface ships, and by at least 2 attack submarines.

Overall, about 85% of all Tomahawks reportedly hit and damaged their targets (95% launched successfully). Tomahawks were used against Baghdad, particularly when the weather was too bad to permit manned attacks with visually guided bombs. Often the Tomahawk attacks were timed so that the missiles would impact about one hour before a satellite passed over the target and assessed the damage. During the war, Tomahawks were fired from the Persian Gulf, the Red Sea, and the Mediterranean. The war included several submarine launches.

The next version will be Block III. Weapons are now (1991) in development and flight test, and Block III should become operational late in 1992. Its main features are

- (i) a GPS guidance capability to supplement or replace TERCOM. This is particularly important in attacks on coastal targets; otherwise, the missile has to come ashore to orient itself by terrain matching.
- (ii) an improved DSMAC (DSMAC 2A) for terminal guidance, better able to compensate for diurnal and seasonal changes in landscape appearance.
- (iii) a new 750-lb (rather than 1000-lb) unitary warhead using insensitive explosives and a programmable-delay fuze. It will leave extra weight for fuel (for about 30% greater range).

Later Tomahawks should incorporate a more efficient engine (F107-WR-402) with 10% more thrust (660 lb; 20% more under hot conditions) and about 3% lower specific fuel consumption, and a more powerful Mk 111 booster. The booster will permit submarine-launched weapons to carry the same fuel load as current surface ship-launched missiles, hence to achieve the same ranges. The new engine is more reliable (it doubles the engine recertification time to 6 yr), and with the extra fuel capacity it should increase TLAM-C's range to about 900 nm. The corresponding change in TLAM-D would be to replace the aft payload bay with fuel, adding about 100 nm of range.

The first successful Block III test occurred on 13 February 1991. Current plans call for 1795 Tomahawks to be remanufactured to Block III configuration: 401 in FY92, 301 in FY93, 267 in FY94, 349 in FY95, 421 in FY96, and 56 in FY97. Reported plans for the production of new Tomahawk Block III missiles, as of February 1991, follow: FY92, 326; FY93, 290; FY94, 282; FY95, 282. An FY91 contract for 400 Tomahawks, including 287 BGM-109Ds (\$422 million, \$1.06 million per missile) was awarded late in January 1991.

Tomahawk flies to a preset point in space. Autonomous terminal guidance (several approaches to which were shown at the 1990 Navy League show) would allow it to decide to attack a specific target in the target area, e.g., an airplane whose position was not definitely known when the missile was launched. Possible approaches include mm-wave radar, laser radar, SAR, and IIR.

As of January 1991, LRCSW has been reduced to R&D status (concentrating on guidance) because of budget cuts. General Dynamics and McDonnell Douglas have proposed a Tomahawk Block IV to replace it. Block IV is to have better mission-plan-

ning capability using different sensors, including the fully autonomous attack sensors that had been proposed for LRCSW (now dead). There seems little chance of adopting the LRCSW unducted-fan power plant because the current range of Tomahawk seems sufficient for nearly all contingencies.

STRIKE/SURFACE WARFARE

Although they received the greatest publicity, guided bombs and stand-off missiles accounted for only a small percentage of the total bomb tonnage used during the Gulf War against Iraq. Total figures on bomb numbers have not been released. The U.S. total bomb *tonnage* was 88,500, of which 6520 tons (7.4%) were precision weapons. General Merrill McPeak, the U.S. Air Force Chief of Staff, immediately after the war claimed a 90% success rate for the air force's laser-guided bombs, but that figure was probably somewhat exaggerated. The weapons in question were mainly laser-guided (Paveways: GBU-24s and a few GBU-27s and -28s), but a few electro-optically guided bombs were also used (e.g., the GBU-15s against the oil terminal pumping the great oil slick into the Gulf). The U.S. Navy used a small number of Walleyes and a very few Skippers.

The Royal Air Force dropped a total of 6000 bombs, and about 10% of them were laser-guided 2000 pounders. This figure may not include the 100 JP-233 runway-attack munitions dropped by Tornados. The typical load-outs were three heavy laser-guided bombs by a Tornado (designated either by the Tornado, using a TIALD pod, or by an accompanying Buccaneer) and four or six 500-lb unguided bombs by a Jaguar (6 for targets in Iraq, where the air defenses had been thoroughly destroyed, 4 plus an ALQ-101(V)10 jamming pod and a Sidewinder [later, 2 Sidewinders overwing]) in sorties over Kuwait, where air defenses were not destroyed until late in the war.

French aircraft were used mainly in airfield attack and for close air support in Kuwait. They fired AS 30L missiles but apparently did not drop laser-guided bombs. These aircraft also used the BAP 100 runway-busting munitions (Durandal is an export weapon only). Reportedly, they soon ran out of French weapons and had to be rewired to take U.S. cluster and iron bombs. Presumably, rewiring was necessary because France did not accept the NATO weapons standards.

It seems unlikely that other coalition air forces used guided air-to-ground weapons.

FRANCE

◆ AS 12

This lightweight air-to-surface missile is carried by Alouette III, AB 212/204, Gazelle, Lynx, and Wasp helicopters. One AS 12 is equivalent to 1 Mk 44/46 torpedo. Not all such aircraft are necessarily so equipped. A Lynx can accommodate 4 AS 12s, a lighter helicopter 2. Reported users of such aircraft (as of 1990) were Argentina (2 Lynxes, 8 Alouette-IIIs), Belgium (3 Alouette-IIIs), Brazil (9 Lynxes and 8 on order), Denmark (7 Lynxes), Egypt (12 Gazelles and 12 on order)*, France (38 Lynxes*, 13 Alouette-IIIs), Germany (14 Lynxes), Greece (4 Alouette-IIIs* and 16 AB 212s), India (18 Chetaks, the domestically built Alouette-IIIs), Indonesia (1 Alouette-III, 14 Wasps), Iran (7 AB 212s), Iraq (5 AB 212s on order), Italy (12 AB 204Bs and 27 AB 212s), Korea (10 or more Alouette-IIIs, 12 Lynxes), Libya (12 Alouette-IIIs), Malaysia (6 Wasps), Mexico (4 Alouette-IIIs), Netherlands (22 Lynxes), New Zealand (9 Wasps), Nigeria (3 Lynxes), Peru (6 AB 212s), Pakistan (4 Alouette-IIIs), Peru (6 AB 212s, 2 Alouette-IIIs), Portugal (5 Lynxes), Seychelles (2 Chetaks/Alouette-IIIs), Spain (11 AB 212s*, 10 Sea Kings*), Thailand (10 Bell 212s), Turkey (3 AB 204s and 9 AB 212s), United Kingdom (78 Lynxes), and Venezuela (6 AB 212s). Asterisks indicate aircraft definitely carrying AS 12 missiles. British, Brazilian, German, and Korean Lynxes carry Sea Skuas instead. Italian AB 212s carry Sea Killer (2 per helicopter). AS 12 can also be carried on board a Sea King (which usually carries a heavier missile, Marte or Exocet), 4 per helicopter.

◆ AS 15TT

During the war against Iraq, the Royal Saudi Navy reported firing AS 15TTs from its Dauphin helicopters against 5 Iraqi patrol boats.

◆ Excalibur (MP 22)

SAMP, which manufactures the standard French bombs, is developing an inertially aided version of the standard 250-kg bomb. It incorporates a slow-burning (15-sec), low-thrust rocket motor for positive flight control. Target coordinates are entered by the attacking airplane 10 msec before launch, and the estimated CEP is 30 m [100 ft] at a range of 10 km. Dimensions are 273 mm × 2.25 m (tail span is 546 mm).

GERMANY

Because of changing German priorities, Kormoran 2 will probably enter service in 1993 rather than in 1991. The German HARM program, begun in 1987, will be completed in 1992.

ISRAEL

◆ CR-2800

Reportedly, only 3 CR-2800s were made, 2 of which were installed on board Westwinds for maritime surveillance (the third was a ground-system prototype). As of early 1991, 1 of the 2 Westwinds had reportedly been destroyed.

◆ Owl ESM System

The known users of this system are Israel (4 or 5 on Aravas) and Thailand (3 on Aravas, 1 in a ground station). Likely users are Argentina (possibly on board the modernized S-2Es) and South Africa.

ITALY

◆ Otomat

A 1989 Matra proposal for an air-launched Otomat seems to be proceeding to development. The Italian navy's Harriers are the most likely initial platform.

NORWAY

◆ Penguin

In addition to the 64 missiles already under contract, the U.S. Navy plans to buy 193 more during FY90-93, with authorization for full production expected in 1991 (but note the lower figures, totaling 106, given in the FY92-93 program, below).

USSR

◆ Air-to-Surface Missiles

Here is further information on Soviet air-to-surface missiles:

AS-2 This is probably the missile the Soviets call Burya. The service designation is K-10; the design-bureau designation is RSL-1 (*Raketniye Sniard Lavochkina*, or Rocket Weapon developed by the Lavochkin design bureau).

AS-3 A strategic weapon developed by the MiG bureau, this is K-20. The MiG bureau absorbed many missile designers in 1950-51, and its missile-design group broke away as a separate bureau about 1956-57.

AS-6 Its Soviet designation is RSR-5, presumably indicating a different design bureau (R).

AS-10 The Soviet designation is Izd (*Izdeliye*, or Object) 69. This weapon is also designated Kh-25L. The antiradar version of the same missile, AS-12, is Kh-25MR. There is also another version, apparently lacking any NATO designator, that the Soviets designate Kh-25P. It is radio command guided.

AS-11 The dimensions of this missile are also given as 32 cm × 4.3 m (span is 1.2 m); weight is 420 kg (warhead is 130 kg). Range is 50 km. AS-11 entered service about 1978.

AS-12 Its dimensions are also given as 30 cm × 3.85 m (span is 90 cm); weight is 300 kg, and range is 35 km. AS-12 entered service about 1978. AS-12 is the antiradar version of AS-10.

AS-14 The Soviet designation is Izd 64/Kh-29L (L for laser; Kh is the English equivalent to the Cyrillic X). Dimensions are also given as 34 cm × 3.84 m (span is 1.28 m); weight is 625 kg, and the warhead is an adapted 250-kg GP bomb. AS-14 entered service about 1980. A striking feature of the missile is the small-diameter laser seeker on the nose of the larger-diameter missile body.

AS-17 This is reportedly the air-launched version of the new small naval missile, SS-N-25. This weapon was in March 1991 described unofficially as turbojet powered, like Harpoon; it may be based on the Harpoons compromised after the Iranian revolution of 1979. Reported characteristics are as follows: length, 4.5 m; weight, 700 kg (warhead, 250 kg); range, 100 km [55 nm].

Kh-66 This missile is a version of Kh-23 (AS-7). The only obvious difference between the two is that only AS-7 has a prominent fairing above its tail, between the 2 upper tail fins. A history of the MiG design by Piotr Butkowski (who had some contacts both in Poland and in the Soviet Union), recently published in the United States by Specialty Press, lists Kh-66 as guided by a radio beam and as shorter-range than AS-7 (2-6 rather than 9.3 miles), with a slightly heavier warhead (105 vice 100 kg) and much higher speed (Mach 2.0 vice Mach 1.0). Total weight was given as 287 kg [631 lb] rather than 350 kg [772 lb] and length as 3.631 m [11.6 ft] rather than 3.5 m [11.2 ft]. Photographs of both missiles in Butkowski's book show much the same fin configuration and size (both have small canard steering fins and large fixed tail fins, with rockets exhausting out to the side rather than straight back so as not to interfere with the reception of the guidance signal). The same photographs show what appears to be a prominent nose radome on AS-7 (i.e., a darkened area that looks like dielectric), a feature that cannot be consistent with the use of radio command guidance. The combination of steering canards and side-exhaust rockets is similar to that in the first Soviet air-to-air missile, AA-1 (RS-2U).

◆ Su-27

A new version of the Su-27 carrier-based fighter has appeared, with side-by-side seating, with what appears to be a laser designator, and with what seem to be stronger underwing hard points for weapons. The nose is reshaped, with chines on its sides (the plane thus may lack a conventional radar); an underbody pod may accommodate a FLIR. This version has landed on the Soviet carrier, and it may be the prototype of a future Soviet carrier strike bomber. However, there is also evidence that it is a carrier trainer, the conventional tandem layout not providing enough visibility from the rear cockpit.

UNITED KINGDOM

◆ ALARM

ALARM antiradar missiles intended for tactical trials were used tactically (and successfully) in the Gulf War instead (January 1991). In all, 100 were fired.

UNITED STATES

The FY92-93 program (as announced in February 1991) calls for (unit cost is for FY92)

	FY91	FY92	FY93	Unit Cost
Harpoon	160	—	—	N/A
HARM	1320	749	215	\$281 thousand
Hellfire	1198	—	1000	N/A
Penguin	40	42	—	\$1.14 million

Tacit Rainbow has been canceled. No further purchases of Maverick are expected. No unit cost was given for Harpoon

(since no more are being bought), but funding is provided in both FY91 and FY92, presumably largely for modifications and support equipment. The Penguin purchase follows 24 in FY90.

The new budget includes funds (\$7.5 million in FY92 and \$7.3 million in FY93) for a new air-launched saturation system.

One surprise of the Kuwait war was that unguided bombs made little impact on dug-in Iraqi armor, whereas the enemy tanks could quite easily be destroyed one by one using laser-guided 500-lb (Mk 82) bombs. This was such a surprise that stocks of the light laser-guided bomb kits ran short, whereas there was no shortage of kits for Mk 83 and Mk 84 bombs. There was also some unhappiness that Walleye, Mk 83, and Mk 84 could not penetrate bunkers and were not effective against bridges. I-2000 was quite effective in these roles. The approximate total of U.S. Navy and Marine Corps expenditures of short-range guided weapons was as follows: Walleye, 130; Skipper, 5; HARM, 900; Shrike, 25; Mk 84 LGB, 260; Mk 83, 210; Mk 82, 420; Maverick, 40; and laser-guided cluster bombs, at least 550 (this figure was accurate only until the ground campaign began, and it does not include the marines' expenditures). Several SLAMs were fired after the first success.

About 6000 Rockeyes and APAMs were dropped (so the guided bombs amounted to just under 10% of the total). Available figures suggest that for the navy alone, laser-guided bombs dropped prior to the ground campaign amounted to 22.6% of all Mk 84s, but to only about 2.5% of all Mk 83s and Mk 82s (i.e., of lighter weapons). Such figures would correspond to a prewar doctrine stressing the precise destruction of important fixed targets but calling for the area bombardment of troop concentrations.

◆ Hellfire

The Israeli navy is buying a version of Hellfire for its fast patrol boats (*Dvora* and successors). This version will use an electro-optical FCS with an associated laser designator. This choice follows a bad experience in which a *Dvora* was not fast enough to run down a boat filled with terrorists and thus could not bring her 20-mm gun into range. The Israelis were apparently impressed with the Swedish coast-defense version of Hellfire. The new FCS will be installed on larger Israeli craft as a backup to their radar FCS (for Barak and Phalanx). The Swedish navy, which uses Hellfire for coast defense, also carries it (on its tripod) on board the new Stridsbat 90 anti-invasion landing boat. Hellfires so carried can be dismounted for use ashore after the boat grounds.

◆ HARM

The low-cost seeker version was first fired on 20 December 1990; it will compete against Texas Instruments's seeker for Block IV missiles.

◆ Senior Pennant

The stealthy U.S. successor to MSOW may be a Northrop program conducted for the air force, Senior Pennant. It was scheduled to complete full-scale engineering development at the end of 1990, at a program cost of \$1 billion.

◆ Harpoon

SLAM (AGM-84E) was used in combat early in the Gulf War (January 1991) when a pair of missiles launched by an A-6E from the *Kennedy* (and guided by an A-7E) hit a hydroelectric power plant; the second missile flew through the hole made by the first. These were prototype missiles; the full-scale production order is not expected until late in FY91. SLAM is programmed before launch, using GPS to achieve a 16-m accuracy in mid-course flight. Like Tomahawk, it flies several legs to avoid enemy air defenses. The data link is used only for the last 60 sec before impact. Complex flight paths are difficult to design; reportedly, preflight planning requires $\frac{1}{2}$ –2 hr, then 30 min for typing into a prelaunch computer (to translate into mission data for the missile), 5 min to load those data into a prelaunch data memory loader, and 5 min to load data into the missile

itself. The prelaunch loader can hold up to 64 missions (in groups of 4, presumably corresponding to the capacity of an A-6E). Presumably, the Tomahawk APS will also be able to plan SLAM missions, and it should be able to generate mission data directly and much more quickly. Reportedly, production SLAM missiles will be redesigned for better performance and lower unit cost. The current version incorporates existing components (such as the Maverick seeker and the Walleye data link) to cut development time and cost, but they add length and weight and therefore cut the missile's performance (for example, the missile has to cruise in an inefficient nose-up attitude). Better component integration would increase the missile's fuel capacity. The production missile may also incorporate a more efficient engine or relocated (or larger) wings. A better concrete-penetrating warhead is also under consideration.

AGM/RGM-84D, the dogleg (waypoint) version, requires SWG-1A rather than SWG-1 for mission planning.

The launchers are (i) Mk 140, a lightweight version (17,472 lb loaded) on board the PHMs; and (ii) Mk 141, the shock-hardened version (27,126 lb loaded) on other ships. Missiles are fired at a fixed elevation of 35 deg.

◆ GBU-27

This is the laser-guided (Paveway III) version of the I-2000 concrete-penetrating bomb, used extensively against Iraq by the U.S. Air Force during the Gulf War. There is also an I-2000 version of GBU-15 designated GBU-15-I. An I-750 or I-800 warhead is in development for use with the Israeli Popeye (Have Nap) guided bomb, to replace the current 750-lb general-purpose bomb.

◆ GBU-28

Lockheed developed this heavy bunker-buster within 22 days (from request to attack). The sled-test and safe-escape drops were conducted on the 21st day; on the 22nd, the final day of the war, 2 GBU-28s penetrated a deep command bunker in Baghdad. These bunkers had been immune to attack by other U.S. weapons, and the effect of the attack was to demonstrate clearly that Saddam Hussein and his associates enjoyed no sanctuary whatever. Such a demonstration will probably be very important in any future operation analogous to Desert Storm. The very long, slender bomb (150.75 in for the bomb proper, excluding fins and homing head; 225.0 in overall; 4414 lb plus 258 lb for the guidance kit) had to be carried externally by an F-111 (the internal bay was too short). The bomb was made from a surplus 8-in/55 naval gun barrel filled with explosive.

◆ Antiradar Missiles

The U.S. Air Force used small numbers of Shrikes and Standard ARMs during the Gulf War, clearing out inventories of these obsolescent weapons before standardizing with HARM. The navy and marines also fired fewer than 25 Shrikes. Presumably, this weapon is no longer being carried in the active inventory.

UNGUIDED MUNITIONS

Further details of 2 major U.S. types extensively used in the war against Iraq follow.

◆ CEM (CBU-87/B)

The combined effects munition, which entered service in FY86, was intended to overcome the limitations inherent in earlier CBUs. CBU-52 was effective against people and light vehicles (or helicopters) but not armor; Rockeye could defeat armor but did not produce enough fragments to kill people or destroy large numbers of light structures, nor was it considered incendiary enough. The existing CBUs also required the delivering airplane to fly relatively high (i.e., into enemy fire) to ensure that the bomblets dispersed properly, and all but Rockeye produced doughnut-shaped patterns.

CBU-87 is a 1000-lb-class bomb consisting of a dispenser (SUU-65/B) with a time fuze (delays of 0.63–4.1 sec; the dis-

penser can also carry an optional proximity fuze for a height of burst of 300–3000 ft, carrying 202 BLU-97/B bomblets. Unlike the earlier SUU-30, which released its bomblets into the airstream for self-dispersal, SUU-65 uses its tail fins to spin itself up (to 1 of 6 preselected settings, 0–2500 rpm in 500-rpm steps) for a preselected pattern (70 × 70 to 450 × 150 ft). SUU-65 can be dropped from altitudes of 200–40,000 ft and at speeds of 200–700 kt; it can be lofted (at up to +30 deg) or dropped in a dive (at down to -60 deg). All of these figures are much less restrictive than those for SUU-30. BLU-97/B itself (2.5 × 6.65 in, 3.41 lb) has a scored-steel body (for fragmentation), a zirconium sponge ring (to start fires), and a downward-firing shaped charge (similar to that in a Rockeye Mk 114 bomblet, to kill armor). It is decelerated (to 125 ft/sec) and stabilized (to point down) by a miniature ballute.

CEM benefitted from a marked change in shaped-charge technology since the development of Rockeye: the ratio of charge diameter to thickness penetrated rose from 3:1 in the Rockeye generation to 5:1 to 7:1 in the next generation of air-dropped munitions. In each case, the requirement was to penetrate about 60 mm of tank roof armor, so the result is that much smaller bomblets could be used. Third-generation shaped charges enjoy ratios as high as 14:1. They are now used mainly in antitank rockets, where the requirement is to penetrate increasingly thick armor using a constant-diameter (i.e., constant-weight) round; however, they should ultimately also yield much smaller bomblets. The improvements come from a better understanding of shaped-charge dynamics, from better explosives, and from better machining of the metal cone of the shaped charge. There is also increased interest in lining materials other than copper (e.g., uranium) for their effects in metal-to-metal reactions. The effect of a better ratio is much smaller submunitions, hence more submunitions per unit volume, i.e., greater efficiency.

◆ I-2000 (BLU-109)

This hard-structure penetrator was used successfully, in a laser-guided version, against Iraqi aircraft shelters and also against Iraqi bridges over the Tigris River. I-2000 was designed specifically to attack hard concrete structures such as the Warsaw Pact hangarages in Eastern Europe; it was intended for use in electro-optical and laser-guided bomb systems. It was shaped specifically to mate with the GBU series but can also be dropped unguided. The existing Mk 84 GP bomb was not considered hard enough to penetrate (it had, after all, a lighter case so that it could produce a balance of fragmentation, blast, and penetration). Even attacking nose-on, a Mk 84 could not penetrate more than about 3.5 ft of concrete, and it could not penetrate at all at an angle greater than about 55 deg to the target's surface. Nor could the existing Mk 84 fuze survive the shock of penetration. The goal of I-2000 was to penetrate 6 ft of concrete at 0 deg and to survive (without ricochet) out to an angle of 30 deg to the target's surface (where it could penetrate about 2 ft). The thicker casing cost 340 lb in explosive content. The fuze problem was cured partly by eliminating the nose fuze in favor of a tail fuze. I-2000's characteristics (Mk 84 in parentheses) are as follows: dimensions, 14.5 × 95.0 (18.0 × 97.7) in; weight, 1925.5 (1902.1) lb; case thickness, 1.062 (0.562) in; and case-material yield strength, 170 (70) ksi. Fuze delays for I-2000 are 0, 10, 25, or 60 msec. Because the casing is so much heavier than that of Mk 84, I-2000 produces larger fragments, so an airplane dropping it unguided needs much greater altitude to escape them. Because its ballistics differ from those of Mk 84, in some cases it cannot be dropped accurately unless FCSs are modified. For example, as of early 1990, an F-16 could drop I-2000 accurately at low angles below 5000 ft or at high angles (dive/glide) above 5000 ft (giving a 37.7-ft estimated average miss distance) but not in a loft (which gave a 1200-ft average miss distance). Presumably, similar figures apply to naval attack aircraft.

I-2000 was developed by the U.S. Air Force Armament Laboratory and completed initial tests in FY83. It was then tested (in a program called Have Void) with GBU-10, -15, and -24 guidance packages.

◆ Advanced Bomb Family (ABF)

Three competitors for the ABF contract (500- and 1000-lb bombs) were displayed at the March 1991 U.S. Navy League show: the Lockheed concept displayed earlier, a Martin Marietta design, and a McDonnell Douglas design. Raytheon/Chamberlain is also a competitor, but its design was not shown. Among those shown, Lockheed's is unique in using folding fins. The 500-lb version is intended to maximize blast/fragmentation, while the 1000-lb version is a semi-hard-target penetrator. Dimensions of the Lockheed ABFs are 500 lb, 10.70 × 82 in; and 1000 lb, 10.70 × 102.35 in (diameter does not include the fixed fins). Dimensions of the Martin Marietta version are 500 lb, 11.75 × 74.38 in (fin span 16.0 in); 1000 lb, 11.75 × 100.88 in (fin span 16.0 in). Martin Marietta claims 15% better Pk than the Mk 80 series bombs, and a 20% improvement in dispersion through better aerodynamic design. All of these bombs include provision for inertial guidance.

◆ ALR-67 ASR

The ASR differs in architecture from other U.S. airborne RWRs in that its RF receiver is channelized (a technique more normally used in ELINT). Hughes claims that a channelized receiver can distinguish weak threat signals even in the presence of strong radar or jamming signals from a nearby wingman. The first 10 units should be produced in 1992, with operational evaluation in 1993, and low-rate production approval sometime in FY93.

◆ ALQ-167A(V)1

Compared with ALQ-167, this version adds a range gate stealer and aft radiation capability. Frequency range is 4–11 GHz in 2 bands (G: 4–8, I: 8–11). Output in G-band is 2 kW ERP, in I-band is 4 kW ERP. Dimensions are 10 in (dia) × 138 in. The pod contains 2 oscillators, an amplifier, and a transmitter. All of these components are types associated with DLQ-3 (presumably, the two systems are nearly identical). Weight varies with configuration (236–320 lb).

◆ AVR-3

AVR-3 is the U.S. designation of the Israeli Elisra SPS-65 helicopter radar/laser-warning receiver, consisting of SPS-20 integrated with the company's LWS-20 laser-warning receiver. The U.S. Army and the U.S. Navy are now jointly evaluating AVR-3. Frequency range (RWR) is 0.7–18 GHz for pulsed radar and 6.5–18 GHz for CW radar. SPS-20 uses a superheterodyne receiver. Information is presented on a 3-in alphanumeric display, which shows emitter type, relative bearing, and relative (assumed) lethality for up to 16 threats. There is also an audio alarm for the pilot. The receiver can be integrated with a decoy dispenser. Information is automatically recorded for later analysis.

◆ DLQ-3

This active airborne ECM system ("Hooter") is used primarily for training. It consists of broad-band multimode equipment remotely programmed to simulate threat radars and threat power levels, both radars and jammers. DLQ-3A introduced remote tuning of spot noise, a dual-mode dwell/walk function, and carrier blanking in the dwell mode. The current operational version is DLQ-3B. This set covers 4–12 GHz.

◆ TALD/ITALD

In a brochure distributed at the Navy League show in March 1991, Brunswick claimed that, launched at 10,000 ft, ITALD would achieve a range of about 150 nm, most of that at 20,000 ft and at Mach 0.8. Alternatively, it could fly in at very low level at Mach 0.73 and then pop up to 10,000 ft about 100 nm from its launch point. These figures compare with a range of 68 nm when released at 40,000 ft at 250 kt, or 14 nm when released at 2,000 ft at 250 kt. This brochure also stated that the chaff version of TALD carries 80 lb of chaff, which it releases in 40 increments. The total weight is 400 lb.

ANTIAIRCRAFT WARFARE

CHINA

◆ ERC-1

This Chinese decoy-launching system was announced in 1988 by the China Shipbuilding Trading Co. ERC-1 consists of 15 tubes and a fire-control unit and fires IR or chaff decoys singly or in salvos. Decoy modes are attraction (persists in the air for 2 min), distraction (6 min), and dump (4 min).

FRANCE

EXPENDABLES

As of early 1990, no MAGAIE decoy systems had been sold. This system is presumably dead. A French article published in 1990 claimed that 18 navies had bought DAGAIE (the published figure 2 years earlier was 15).

◆ DAGAIE

To date, known sales have been to Argentina (11 ship sets, plus 2 being installed, for the MEKO ships and A69s, sold in 1980), Bahrain (6, plus 2 being installed, for the FPB 62- and TNC 45-class boats, sold in 1979 and 1984), Colombia (4 for the FS 1500-class frigates, sold in 1980), France (31, plus 14 being installed, the most recent orders being for the *Floreal* class), Indonesia (2, plus 2 being installed for the Lurssen PB 57 boats, sold in 1982), Italy (for 12 ships, delivered in 1987; presumably, for operations in the Persian Gulf), Kuwait (8 installed on the FPB 57- and TNC 45-class boats, sold in 1980), Malaysia (4 sold in 1981 for FS 1500-class frigates), Peru (ordered for the 2 ex-Dutch cruisers, but never paid for and therefore not delivered), Morocco (2 sold for the *Descubierta*-class frigate in 1979), Qatar (3 double sets for the Combattante-III-class boats, sold in 1981-83), Saudi Arabia (8 sold in 1980 for the *Al Madinah*-class frigates), Thailand (2 sold for the PFMM Mk 16-class corvettes in 1983), Tunisia (3 sold for the Combattante-III-class boats in 1981), and the UAE (10 for the Type 62-, FPB 38-, and TNC 45-class boats). The other 3 users are unknown; Italy was the 16th, and the first to order DAGAIE Mk 2. China may have bought DAGAIE as part of its large-scale purchase of French equipment, much of which appeared on board the 2 Jianghu-IV-class frigates. It seems likely that the last 2 purchases were emergency procurements for the Gulf operations; the likely candidates include Belgium and the Netherlands, for mincraft or mine-support units. The other *Descubierta*-class corvettes (for Egypt and Spain) use the U.S. Hycor/Mk 137 system.

◆ SAGAIE

Purchasers include Italy (the *Animoso* class), France (8 systems for the *Clemenceau*-class carriers and air-defense frigates; on order for the carrier *Charles de Gaulle*), and Saudi Arabia (for the 3 new FL 3000-class frigates). The Italian sales may be DAGAIE Mk 2, which fires both DAGAIE and SAGAIE rounds.

◆ French Naval Radars

Arabel is to be carried on board the new French-built Saudi frigates (Sawari 2 program). The corresponding *Lafayette*-class ships of the French navy will have simpler Sea Tiger Mk 2 radars. The *Lafayettes* will have no sonar at all because they are intended for the Persian Gulf and the Indian Ocean. The Sawari 2s will have sonars, like the Sawaris.

Mars is being offered with the MR-05 antenna under the designation Mars 05; in the *Floreal*s it will still have a reconditioned DRBV 22 antenna. In this form it should be able to detect aircraft at 60 nm, and the optional automatic tracker can accommodate up to 100 tracks.

Reportedly, there is also to be a Jupiter 08 (Jupiter electronics and the LW-08 antenna).

MRR is in fact a 2½D type, as suggested in the main text (search with synthesized fan beam, tracking with a pencil beam). It replaces the earlier Triton in the Thomson-CSF radar series, and a corresponding Vega successor is being developed.

MRR and MW-08 compete within the Thomson-Signaal group, and one will probably be dropped. MRR is the likely victim since MW 08 has already been sold to Greece and Portugal for MEKO 200 frigates.

DRBJ 11 scans electronically in both elevation and bearing to detect and confirm a target on a single scan, then begins tracking on the second scan. That is, once a target has been detected, the beam skips back to redetect it before the array has fully turned away. In all, 4 sets have been manufactured, for 2 AAW destroyers and for the nuclear carrier. Thomson-CSF has suggested that the same radar, fixed in bearing, could be used to support an anti-ballistic-missile system ashore.

SCORE replaces TRS 3410 as a coastal radar. SCORE has a very similar antenna. The first sale, concluded in March 1991, was to Cyprus for control of Exocet missiles. SCORE operates in X-band and can have either a 4.8-m foldable or a 2-m one-piece antenna. It can be fixed or mobile. With the larger antenna, it can detect a 10-m² fast patrol boat at 124 km, and a 2-m² fighter at 72 km. The corresponding figures for the 2-m antenna are 83 and 48 km. SCORE is a pulse-compression radar (very short effective pulse to overcome sea clutter) with circular polarization (to overcome rain), high transmission power, and pulse-to-pulse frequency agility. The associated processor is a 32-bit machine programmed in ADA.

CTM (*conduit de tir multisensor*) is the Crotale NG fire-control system, but it has wider application. The *Lafayettes* carry 2 for GFCS and MFCS. This system replaces Castor III and perhaps should be called Castor IIJC (C for compact or Crotale). Castor III itself has died with the Satan CIWS. Castor IIC is the latest and last improvement of Vega. It is particularly effective for GFCS because it incorporates an internal gyro for high accuracy. The associated Ku-band, Doppler, monopulse radar has a TWT transmitter for frequency agility and pulse compression (processing includes FFT Doppler filtering). It automatically acquires a fighter at 30 km and an antiship missile at 18 km. The other sensors on the mount are an IR camera and a TV camera.

GERMANY

EXPENDABLES

Hot Dog/Silver Dog are simple adaptations of standard armored-fighting-vehicle devices. The other land-combat rounds are smoke, thermal smoke, and fragmentation grenades.

INDIA

Besides RAWL and RAWS, Bharat Electronics currently markets a second S-band naval radar, RAWS-3, and a pair of surface-search or navigational radars, Rani and Rashmi. RAWS-3 is a pulse-compression radar with variable pulse width, described as similar to RAWS. Rani/Rashmi are similar to the Signaal ZW-06; each uses a 24-in raster display. Rani uses a 6-ft slotted array; Rashmi uses a parabolic antenna. Both operate at X-band (peak power, 40 kW; range discrimination, 20 m; maximum range, 20 nm on a small vessel and 12 nm on a helicopter).

There are also RAWL-2, a copy of Signaal's LW-08, and Indra (Thomson-CSF's Tiger). Indra exists in naval (Indra 1) and land (Indra 2) versions. Bharat also manufactures the Signaal Flycatcher land FCS radar and a Contraves Seaguard tracker module (probably TMX/KA) under license, the latter as Shikari.

Bharat Electronics was largely established by Signaal, which is why it manufactures Signaal products under license.

The new *Delhi* (Type 15) destroyer is to be armed with the new Trishul missile, on a twin launcher, plus Soviet surface-to-surface missiles (Styx variants), a single Soviet 76-mm gun, and 4 twin 30-mm close-in defense guns (2 mounts on each side). The main air-search radar will probably be RAWL-2, with target acquisition/missile detection by Indra. Contraves is largely responsible for the FCS, which employs 3 Shikaris on a data bus (as in Seaguard). Trishul itself is, in effect, an Indian interpretation of the British Sea Wolf system (which BAe long tried to sell to them), using an airframe adapted from that of

the Soviet SA-6. Trishul is now flying, using a Flycatcher for control (the production version will be controlled by Shikari).

The ship would have initially had 1 tracker for each of the port and starboard 30-mm batteries and a third for the 76-mm gun and the Trishul missiles, all with NTDS links to a central computer system (the Indian-built IPN-10, which is now standard in that navy). Contraves convinced the designers to opt for a bus so that directors can shift between weapons. Trishul's range is about 20 km. The requirement was to acquire at 20 km and fire and intercept at 14 km. The Indians rejected a Contraves suggestion that C-band would be better than S-band against sea-skimmers (they specifically rejected AWS-6).

INTERNATIONAL

◆ ASRAAM

As of February 1991, the ASRAAM program was still alive, though badly weakened by the loss of the German partner. The British government was considering the proposed MICA-SRAAM as a lower-performance but less-expensive alternative. It rejected a U.S. proposal to use the new version of Sidewinder because such a choice would violate the MoU on the basis of which the Europeans were to buy the U.S.-developed Sparrow replacement (AMRAAM) while developing the Sidewinder replacement (ASRAAM); the United States has already dropped its end of the agreement by abandoning ASRAAM.

◆ PILOT

Under the Signaal-Thomson contract, this name can no longer be used. The Signaal version of the basic technology, Scout, uses a different antenna and is dramatically less expensive (reportedly, by a factor of 5 or 6 in price).

JAPAN

The following is additional information on Japanese naval radars. In the designations, some first letters are O for on board (i.e., ship), H for *Hiko-ki* (airplane), and R for portable (*Raku ni Moteru*, literally, easy-to-carry). The prefix N means system; it is currently used mainly in ECM. In the following notes, frequency bands are generally identified in the ECM system, not the conventional radar-design system.

OPS-9 is an I-band radar for medium minesweepers. Versions are OPS-9B and -9C. The original OPS-9 had 2 separate displays, 1 for true and 1 for relative position. Both are combined in OPS-9B and are transistorized. This radar has a very narrow beam for accurate position finding and for picking up buoys that are marking a swept channel.

OPS-11 operates in B-band. OPS-11B is a retrofit with an improved amplifier. OPS-11C incorporates MTI. These radars have much greater range than the 3D sets with which they are used. The array on top is an IFF.

OPS-12 is a naval version of a land-mobile 3D radar, operating in E/F (S)-band.

OPS-14 operates in D-band. Versions are -14B and -14C. OPS-14B has MTI. OPS-14C has its magnetron replaced by a klystron for coherent (pulse-compressed) operation.

OPS-16 is a G-band surface-search radar for major units. Versions are -16C and -16D (a solid-state version of -16C with different PRF).

OPS-17 and -18 are surface-search radars for frigates and large auxiliaries. OPS-17 uses medium PRF. The OPS-18 transmitter is frequency-agile. It is an ARPA radar capable of displaying 10 targets simultaneously. OPS-18-1 is similar but more sensitive.

OPS-22 is a J-band, high-sensitivity radar with high data-processing capability. Used on icebreakers, it is designed for great resolution.

OPS-24 is a D-band, 3D, long-pulse (pulse-compression) radar using active array elements. Heat is dissipated in a pair of heat exchangers flanking the array, and the IFF array is carried below the main array. Coverage is from the zenith to below the horizon. This is the first active array radar to enter service. It may

be related to the higher-frequency (C-band, in conventional nomenclature, i.e., 5 cm) FCS 3.

OPS-28 is a G-band set to detect low-fliers. It uses a TWT transmitter and a crossed-field amplifier (CFA). The antenna is stabilized (roll up to 15 deg, pitch up to 7 deg).

FCS 1 is an I/J-band set comparable in performance to the U.S. Mk 57 or Mk 63. FCS 1 can deal with subsonic aircraft at medium range. It sets fuzes and computes lead angles and ranges.

FCS 2 has limited ECCM features. The dome protecting FCS 2-12 covers separate search and track antennas, as in the Signaal WM20 series "egg." During search, all radar energy goes to the search antenna. Once a target has been detected, 40% of the total energy goes to the tracking antenna. A 1-m² target can be detected at a range of 30 km and at an altitude of 10-15 km. An 0.5-m² target can be detected at 10 km. FCS 2-12 is a combined gun and missile FCS. FCS 2-23 is an upgraded version with better CW injection for missile guidance. It is an MTI set using a TWT transmitter for frequency agility. FCS 2-22 is an upgraded FCS 2-21 (GFCS) capable of tracking up to 100 deg rather than 82 deg elevation.

FCS 3 has better ECCM features than FCS 2. FCS 3 is a rotating C-band (5-cm) TWS phased array. The prototype went to sea in 1990. The array spins very rapidly, and directors are slaved to it via its computer. The original concept was a 4-faced array, but the prototype had 2 faces.

◆ Sea Gnat

Orders for Sea Gnat rounds, as of December 1990, were as follows:

	Mk 214	Mk 216	DLA launchers
Denmark	1000	—	—
Netherlands	3500	—	—
Spain	1000	—	—
United Kingdom	3500	10,000	48
United States	33,000	7,000	—

ISRAEL

EXPENDABLES

Known users of the Rafael decoy system (distraction system) are Chile, Israel, South Africa, and Taiwan. Other users are probably Argentina, Singapore, Sri Lanka, and Thailand.

Known users of the Elbit ACDS chaff system are Chile (22 systems), Israel (122), South Africa (28; 8 more scrapped), and Taiwan (208). This system fills a large volume by firing all 45 chaff barrels simultaneously.

ITALY

EXPENDABLES

The Breda lightweight chaff system has been abandoned; none had been sold.

SCLAR users are Argentina (the MEKO 360H2 class, supplemented by DAGAIE), Denmark (6 bought for the *Niels Juel* class, not installed), Ecuador (the *Esmeralda*-class corvettes), Germany (the *Hamburg* and *Luneberg* classes; planned for the Type 123 frigates), Italy (major surface combatants, down to frigates; a total of 52 launchers), Nigeria (the *Aradu*), Peru (the *Lupo* class), Turkey (36 launchers on board 9 FRAM destroyers, 6 on board 3 *Koln*-class frigates), and Venezuela (the *Lupo* class).

ESM

The following is further information on Italian Elettronica ESM systems. The standard systems are all variants of Newton. Some systems listed separately in the text are actually variants of Newton Beta erroneously listed under the designation of minor subcomponents (see below). Newton is presumably the successor to FARAD, incorporating an integrated control unit (ELT 211) and a new noise jammer (ELT 318 vice ELT 361). Some ships have cylindrical antennas much taller than the usual ELT

814 and apparently stabilized. In what follows, they are denoted large ELT 814s.

Versions of Newton (designating letter indicates the number of separate jammers) are as follows:

Newton Alpha 100–500-ton ships. ELT 211 plus either ELT 318 noise jammer (ELT 814 antenna) or ELT 521 deception jammer (ELT 828 antenna). Elettronica sold no systems, so it sold all rights to Elta of Israel, which manufactured its version of the system as MN-53.

Newton Beta 250–1000-ton ships. ELT 211, ELT 318 (with 2 large ELT 814 antennas), and ELT 521 (with 2 ELT 828 antennas). ELT 715 is the data-transmission unit used in the Moroccan version of this system, on board the *Lt. Col. Errhamani* (which has 2 large ELT 814s but lacks ELT 828s). The Chinese license-built version uses an ELT 939 transmission box (on board Jianghu-IV and -V class corvettes for China and Thailand). These ships have 2 ELT 814 antennas.

Newton Gamma ELT 211, 1 ELT 318, and 2 ELT 521s (2 or 3 ELT 828 antennas).

Newton Lambda ELT 211, 1 ELT 318, and 3 ELT 521s, or 2 ELT 318s and 2 ELT 521s, in each case with 4 ELT 828 antennas. It may be significant that the Italian navy's version is SLQ-D (i.e., Delta).

Newton Epsilon 5-unit system for the *Andrea Doria* class and *Vittorio Veneto*, with ELT 211, 2 ELT 318s, and 3 ELT 521s. On board the *Caio Duilio*, it currently uses 4 large and 3 small ELT 814s (large ones on the forward starboard side of the bridge, on the port and starboard after sides of the bridge, and on the starboard side aft above the deckhouse atop the helicopter hangar; small ones on the after port and starboard sides of the bridge and on the after deckhouse, both near the corresponding large ELT 814s).

Nettuno is a development of Newton Delta with a second console added to the ELT 211 for ESM analysis (with a larger threat library and a better computer) and to integrate the system directly with a ship's CDS. It also has 2 new phased-array ESM antennas (replacing 2 of the cones of the earlier versions). The jammers feed 4 ELT 828. This is the system on board the *Giuseppe Garibaldi* and the *Audace*- and *Ardito*-class missile destroyers.

NETHERLANDS

◆ MW-08

MW-08 is the 3D air-search radar in both the Greek and the Portuguese MEKO 200-type frigates.

◆ MR-05

A recent Signaal brochure shows transmitter power as 10 kW. Maximum (free space, PD 0.5) range on air targets is 80 km on a 0.5-m² target (SW 3 case), 95 km on a 1-m² target (SW 1 case), and 110 km on a 2-m² target (SW 1 case). Maximum unambiguous target speed (for MTI filtering) is Mach 5. Instrumented range is 107 or 214 km. Resolution is 3.5 deg in bearing and 90 m in range. If a tracker is fitted, it has a capacity of 160 air and surface targets. Antenna width is 4.8 m; weight is 600 kg.

◆ FCS Radars

STING is the current Signaal tracker. It differs from *STIR* in that it incorporates an integrated K-band transceiver (to track low targets) and uses hydraulic rather than electric drive for higher slewing and elevating speeds. *STING* includes an automatic signal processor. Versions are *STING BS* (basic), *STING CW* (adds CWI), *STING EO* (adds IR camera, laser, and TV tracking unit), *STING SW* (Sea Wolf: adds command link, gyro, gathering unit for missiles).

LIROD is K-band radar plus television. Extended *LIROD* adds a laser range-finder (or laser tracker) and an IR camera.

POLAND

◆ Wrobel 2MR

This is a combined gun-missile system (equivalent to the land-based ZUR-23-2S) consisting of a twin 23-mm gun and a single 72-mm Strela 2M (SA-7 series) missile launcher on top. It was first mounted on board the new minelayer/transport *Gnieszno*.

SWEDEN

◆ RBS-70

When she was sent to the Persian Gulf, HMAS *Westralia* was provided with RBS-70 missiles from the Australian army's 16th Air Defence Regiment. Her predecessor, HMAS *Success*, may have been similarly armed. These 2 ships were the first to have been so armed. *Westralia* was also given four 50-cal machine guns for defense against small boats.

EXPENDABLES

Known users of the Philax system are Finland (4, plus more for the Helsinki-II class) and Sweden (82, plus 24 on order). Users of Protean are Egypt (24), Korea (88, plus 16 on order), and Nigeria (2 for the *Erin'mi* class). Protean was also reportedly sold to civilian shipowners during the Iran-Iraq War.

SWITZERLAND

◆ ADATS

It was reported late in 1990 that Oerlikon had abandoned work on the naval version of ADATS (announced in October 1988) because of the lack of any firm customer.

USSR

◆ Head Lights

Recent very clear photographs (such as the one reproduced below) of Head Lights, the SA-N-3 radar, suggest strongly that it is not a monopulse set (as claimed in the main text). It is probably a TWS radar, in which one dish is scanned horizontally while the other is scanned vertically (the 2 small dishes operate similarly to track the outgoing missiles). Such a system can reasonably expect to track 2 missiles flying against 1 or more closely bunched targets. In this case, Pop Group would be the first Soviet naval, monopulse, missile-control radar.

◆ SA-16

A 1990 Soviet brochure for SA-16 (called Igla 1EH) claims that the maximum effective range is 3.0 km (with a maximum altitude of 3.5 km and a minimum of 10 m) and the maximum velocity is 680 m/sec. Activation time is 13 sec (presumably, to ready the missile to fire), and reaction time from target detection to firing is 4.5 sec. Claimed probabilities of engagement against various targets are as follows:

	Head-On	Tail-On
F-4	0.33	0.48
A-10A	0.15	0.19
F-15	0.11	0.32
AH-1G	0.34	0.42
ALCM	—	0.20

As the latest version of the SA-7 family and the first with claimed head-on capability, SA-16 is presumably carried aboard many Soviet and client-state ships (see SA-N-5/8 and SA-N-10). The total system weight is 16.65 kg. The Soviet industrial designation is 9M39 (original version); the developed version is designated 9M313.

SA-19, which may be the missile associated with CADS-1, is designated 9M311.

Recent reports suggest that the MiG-29 fighter's radar suffers from a very narrow search sector, perhaps only 30 deg wide (one report suggests 10 deg), which would be appropriate for a ground-controlled intercept system but might be less effective

for an aircraft operating from a carrier without any associated AEW system.

◆ MiG-29 Weapon System

The weapons-system computer apparently selects which weapon to fire based on radar input. The main safety feature of the system is that several widely separated switches have to be depressed to lock on the radar and fire the weapon. In addition, the radar has a very narrow FoV. Iraqi practice was apparently to tape down some of the switches for quicker engagement. As a consequence, an Iraqi MiG-29 shot down its wingman when the latter crossed into the radar's FoV.

UNITED KINGDOM

◆ Type 1022

Late in 1990 it was reported that the Royal Navy was experiencing sidelobe problems with its Type 1022 radar and that a get-well program was underway.

◆ Naval Radars

Versions of some current British naval radars are as follows:

911(1) GWS 25 Mod 3, 6-barrel launcher for Type 22 Batch II and III frigates.

911(2) Vertically launched Sea Wolf for Type 23 and *Fort Victoria*-class replenishment ships.

911(3) Lightweight Sea Wolf for Type 42 Batch III destroyers and the *Invincible* class.

996(1) Type 992 replacement for both *Invincible*-class and Type 42 destroyers (can support Sea Wolf); also on the *Fort Victoria* class.

996(2) Version for Type 23 frigates.

1006(1) 9650 MHz for submarines.

1006(2,3) 9445 MHz for major surface units.

1006(4) 9425 MHz for mine-countermeasures craft (Hunt and Ton classes).

The Royal Navy no longer uses Types 1002/1003, but they may survive on board exported *Oberon*-class submarines.

The Type 994 designation has been applied not only to the converted Type 993 but also to AWS-4 as installed on board *Argus*- and *Castle*-class OPVs.

British fleet auxiliaries (RFAs) operating in the Persian Gulf in 1991 were each provided with 1 battery of Royal Artillery (8 Javelin handheld missiles) for self-defense.

Type 996 (AWS-9) has been sold to Turkey as part of the Track-II version of the MEKO 200 frigate. This is its first export sale.

◆ Laser Dazzle Sight

Film of HMS *London* operating in the Persian Gulf clearly showed a laser dazzle sight (DEC) slaved to the ship's Type 911 radar. The laser dazzle sight is reportedly standard issue on board British warships in the Gulf, and that shown on board HMS *London* seemed to be a production version of the earlier and cruder type previously seen.

◆ Sea Dart

Operating in the Persian Gulf, HMS *Gloucester* engaged the Iraqi Silkworm missiles fired during Operation Desert Storm. Of 2 Silkworms fired, 1 fell into the water soon after it was fired. The official British spokesman stated that a radar operator detected the incoming missile, and that 50 sec after detection 2 Sea Darts were fired. One intercepted the Silkworm at a range of 4 nm, and the other passed through the debris. It appears, then, that detection was semiautomatic at best. The British spokesman stated that the alert watchkeeper noticed a small, fast-moving target, and that this contact was evaluated before it was engaged. If the missile was moving at about 10 nm/min,

it closed about 8 nm during evaluation. Initial detection would have been at about 12 nm, probably about the distance between the destroyer, operating fairly close offshore, and the missile launcher. The dual launch was presumably standard doctrine; at this range, there would not have been any chance for a second attempt to intercept the incoming weapon. The *Gloucester's* success against a missile probably approaching at fairly low altitude suggests that the Sea Dart get-well program was successful. Later it became apparent that the Silkworm was initially detected by the destroyer's UAA-2 ESM set, which provided the bearing onto which her Type 909 was slewed for engagement. The Sea Dart missile was up on the rail and pointed toward the target before the 909 acquired the Silkworm. Reportedly, both UAA-1 and -2 worked very well in the Persian Gulf war, to the extent that ships equipped with them were sometimes used for ESM watch. Reportedly, too, UAA-2 is designed to localize emissions within 2 deg, but it can sometimes do as well as 0.5 deg.

◆ SADIE Processor

As of March 1991, SADIE was reportedly in deep trouble because the parent British MoD program had been canceled. Several systems nominally incorporating it actually use Kongsberg KS500 processors as an interim fit. KS500 has about 10% of SADIE's throughput; it was bought because it has an instruction set compatible with that planned for SADIE. The problem was reportedly a window-addressable memory that was not working as of March 1991. The problem came to light because 2 Canadian ships in the Persian Gulf, the *Athabaskan* and *Protecteur*, were given Kestrel ESM devices as an emergency upgrade; they found that the systems incorporated the Kongsberg boards, not SADIE. It turned out that Cutlass E in the UAE navy also had KS500 boards. Reportedly, the German FL1800S is experiencing great difficulties and was in February 1991 the subject of an AEG-Racal get-well program.

EXPENDABLES

◆ Barricade

Users are Chile (12), Denmark (8 on Stanflex 2000s), Finland (4 on the *Pohjanmaa*), Italy (12 on the *Minervas*), Kenya (4), Malaysia (8), Oman (14), Saudi Arabia (2, plus 10 on order, for the *Sandowns*), and the United Kingdom (28, plus 38 on order). The manufacturer claims that Barricade is also used by a tenth navy. This system reportedly suffers because it is not connected directly to an ESM device; hence the Finnish choice of Matilda/Philax for Helsinki-IIs.

◆ Corvus

Users are Chile (the "County" and *Leander* classes), Greece (the *Kortenaer* class), India (the *Viraat*), Indonesia (the *Fatahilah*, *van Speijk* [note that the Netherlands navy used SRBOC on these ships], and "Tribal" classes), Pakistan (the "County" and *Leander* classes), and the United Kingdom (Type 42 destroyers, the *Bristol*, the *Amazon* class, Type 22 frigates, and the *Leander* class).

◆ Shield

Users are Brazil (16, plus 28 on order), Canada (4, plus 56 on order), Pakistan (12 for FRAMs), Thailand (30 on order), and the United Kingdom (60, plus 48 on order).

UNITED STATES

The FY92/93 program (announced in February 1991) called for the following (cost figures are for FY92):

	FY91	FY92	FY93	Unit Cost
AMRAAM	265	191	159	\$1.07 million
SM-2	790	525	550	\$791 thousand

No further Phoenix production is expected. The program gave no figures for new Sidewinders or Sparrows, although modified versions of both are under development or in production.

◆ SPS-49

Versions of SPS-49 are as follows:

- (V)1 was the original version for cruisers, destroyers, and carriers; all are to upgrade to (V)5.
- (V)2 was for frigates; it has been upgraded to (V)4, which is similar to (V)3 (i.e., it adds a radar video processor), but, like (V)2, lacks the coherent sidelobe canceler (CSLC) of other versions.
- (V)5, which adds ADT, is the upgrade for all (V)1 and (V)4.
- (V)6 is in the first 3 *Ticonderogas*; all are to upgrade to (V)7.
- (V)6 has a radar video processor.
- (V)7 has full ADT. (V)6 and (V)7 differ from earlier SPS-49s in that they use the Aegis cooling system rather than separate coolers of their own.

The radar video processor (RVP), based on UYK-20 in the case of a frigate, is used on board ships that lack the full SYS-2. (V)5 is required to support SYS-2.

◆ SPN-47

SPN-47 is a shipboard version of the marines' TPN-30 MRAALS (marine remote-area approach and landing system) combined with a stabilized glide-slope indicator pedestal. It will presumably replace the current SPN-35 (itself a stabilized version of a land-based controlled landing system) on board amphibious carriers (LHA, LHD, LPH).

◆ SYS-2

Versions of SYS-2 are as follows:

- (V)1 is New Threat Upgrade with SPS-49(V)5 and SPS-48E.
- (V)2 is for *Perry*-class frigates, with SPS-49(V)5 and Mk 92.
- (V)3 is for the LHD 1 class, with SPS-49(V)5 and SPS-52C.
- (V)4 is for carriers, with SPS-49(V)5 and SPS-48E.
- (V)5 is for the LHDs, with SPS-49(V)5 and SPS-48E.

SYS-2 entered service in 1987.

◆ Mk 92 Mod 6

UNISYS claimed in March 1991 that Mod 6 (CORT) offers the following improvements over Mod 2: twice the transmitter power; twice the instrumented range (search and track); 100:1 improvement in clutter rejection; coherent cancellation of second/third time around clutter; an order of magnitude reduction in the minimum radar cross section the system can handle; improved capability to handle target velocities; better ECCM; twice the MTBF; half the MTTR. The STIR tracker provides a horizon-search capability. UNISYS also offers a simplified Mod 6 (for small combatants) without the STIR. In both versions, the combined antenna system (equivalent to the Signaal "egg") offers 8 TWS channels, 2 of which can be used for GFCS (the other 6 are used for track management). The system can engage surface targets while controlling 2 surface-to-air missiles (1 by CAS, 1 by STIR). The CAS feeds a Mk 106 Mod 1 weapons-control console; the STIR feeds a Mk 107 Mod 0 weapons-control console, and the system also incorporates an OJ-194(V)3/UYA-4 PPI display. All 3 consoles receive external (SPS-49, -55 in a frigate) video as well as Mk 92 radar video.

◆ E-2C Upgrade Block III

The FY92 budget includes the Block III upgrade: the airplane will be fitted with a new mission computer, an IRST sensor, and a satellite link.

◆ Sparrow

AIM-/RIM-7P is the current production version, superseding AIM-/RIM-7M. This version has improved low-altitude guidance (LAG), superior subclutter visibility, a reprogrammable missile-borne computer (MBC—see below), an uplink capacity, and an internal digital data bus that provides a better interface to the shipboard or airborne FCS before launch. Raytheon claims that the operational ready rate and reliability are double the specified requirements.

AIM-/RIM-7R, now in full-scale development, was displayed at the 1991 U.S. Navy League show. It adds a nose IR sensor to the usual semiactive radar seeker. AIM-/RIM-7R is being developed under the joint Raytheon/General Dynamics MHIP (Missile-Homing Improvement Program). MHIP also applies to the Standard Missile (SM-2 Block IIIB). The Sparrow missile carries its IR sensor at the tip of its nose because the radar dish usually looks to 1 side as the missile flies a proportional-navigation path. The SM-2 MHIP version has a separate IR sensor in a fairing on 1 side. As of March 1991, a decision on the future course of the MHIP program was expected late in May.

MHIP required a considerable increase in computer capacity. AIM-/RIM-7M had the first programmable missile-borne computer (MBC) in the Sparrow series. Reprogramming required that the missile be decanned, the computer pulled out, and its EEPROMS changed and burned in. A reprogrammed missile had to be tested after modification. AIM-7P uses ERPROMS and can, therefore, be reprogrammed by wire from its umbilical. AIM-7R's requirements were developed while the AIM-7P computer was being redone. Increased capacity was needed mainly for IR-seeker signal processing. The -7P computer was redesigned to free space for 3 IR processing boards. Total computer power is an order of magnitude greater than in the earlier -7M. AIM-/RIM-7R also has a new radome, and the RF-signal processor must compensate for very different internal reflection (including reflection from the IR seeker).

The new front end is wholly retrofittable to existing -7M missiles. The tentative plan is to retrofit existing weapons, beginning with the earliest -7Ms.

◆ Sidewinder

Loral Aeroneutronics (formerly Ford) displayed AIM-9R at the March 1991 U.S. Navy League show. It is currently in full-scale development. This version uses an imaging IR seeker (a visible imaging, focal-plane array and 3-axis-stabilized, high-resolution optics) for increased acquisition range and better clutter and countermeasures rejection. It also has an increased FoR to track off-boresight and maneuvering targets and better aim-point selection and terminal guidance for increased kill probability. AIM-9R is electronically reprogrammable to incorporate future software upgrades. The new front end is completely interchangeable with the existing AIM-9M/9L missile's after end.

Boa-M is a jointly funded General Dynamics/China Lake program to demonstrate the feasibility of modifying the basic missile to fit the tight internal stowage of future stealthy fighters such as the F-22 and F-23. An AIM-9M was modified by fitting the smaller canards of a -9D and by halving the size of the tail fins. A digital autopilot provided dynamic control to make up for the inherent stability thus sacrificed; the result was analogous to a fly-by-wire airplane, which sacrifices inherent stability to achieve greater maneuverability. In a demonstration late in 1990, this Boa-M missile successfully intercepted an F-86 drone from a range of 2 miles (having been fired off center). This shot demonstrated not only the practicality of the reduced-size missile but also its greater agility.

◆ Standard Missile

The prototype SM-2 Block IIIA missile flew at White Sands on 2 March 1991. Performance improvements in this version include ordnance improvements, which may mean a directed-explosion warhead (i.e., the missile rolls toward its target and then fires its warhead directly at it).

For details of Block IIIB, see the discussion of Sparrow above.

◆ RAM

The standard 21-cell launcher is now Mk 49; Mk 43 has been dropped. The project to convert some cells of Sea Sparrow (Mk 29) launchers has been essentially abandoned partly because some major modification of launcher motors would have been required to maintain train and elevation rates. There would also have been major computer changes. In addition, many Sparrow installations are moving to vertical launchers. On the other

hand, the carriers cannot accommodate RAM unless their Mk 29 launchers are modified.

As of March 1991, General Dynamics was under contract for Mk 49 launchers for the U.S. Navy for 2 LCCs (replacing BPDMS) and 4 LHAs (2 each, fore and aft). In each case, TAS Mk 23 is to be added for target designation. On the LCCs, the requirement for fore and aft mountings would entail a redistribution of armament. U.S. Navy planning in March 1991 called for RAM on board the *Spruance* class, the LCCs, the LHAs, and the LSD 41 class.

The Phalanx/RAM program was originally a General Dynamics IR&D project, but the U.S. Navy is now supporting the program. This system will probably be required for the LSD 41 class because they will not be fitted with TAS Mk 23. They will probably use the Phalanx search radar for designation, together with the ship's ESM system.

The first RAM delivery to the German navy is scheduled for the first quarter of 1992; it will probably be operational by mid-year. The prototype German RAM launcher has been installed on board 2 fast patrol boats, first as a stand-alone device and then connected to the boat's command system, which could designate targets and point the launcher. The launcher was then moved to the German land-based test site at Wilhelmshaven for integration with the destroyer, frigate, and fast-patrol-boat combat systems.

The Royal Danish Navy is still an observer in the program; it plans to compete its StanFlex 300 defensive system. The Danish-designed RALS launcher was first test-fired on the Danish naval firing range in June 1990. The most likely competitor is Mistral (Denmark briefly considered the Israeli Barak, too).

General Dynamics and Contraves are developing ISDS (Integrated Self-Defense System), a Contraves Sea Shield gun mount with 5 RAM missiles (from a RALS launcher) on top of it. The total weight will be 6416 kg above decks, 1590 kg below decks.

The RAM II upgrade is intended for IR lock on after launch. If a nonradiating target is detected by shipboard radar, the system selects the all-IR mode (upgraded configuration). Typically, the radar would be the 2D TAS Mk 23. It would, then, generate only a bearing. The seeker is instructed to conduct an expanded vertical search in flight (which would probably involve a 1-bit indication in the launch message). General Dynamics claims that the improved missile will acquire even low-IR-signature threats. General Dynamics is developing the seeker while BGT of Germany develops the signal processing.

◆ SWPS

An industry briefing was held in January 1991, but as of March the acquisition plan was still being drawn up. A formal RFP was to be issued 60 days after the acquisition plan was approved (probably in June). Likely competitors were the AAI/Rockwell gun and missile mount, the Boeing Avenger, the LTV Crossbow, and at least one other (most likely the Bofors Trinity in modified form). This weapon is being bought to equip the new SEAL-insertion craft (a modified version of the Vosper-Thornycroft "Province"-class fast patrol boat), but it may also replace existing 25-mm and even 3-in/50 mounts on board larger ships.

◆ ASAT

The ASAT program was canceled in January 1991. The U.S. Air Force wishes to cancel its participation in the NATO Mk XV IFF program. It may, however, buy Mk XV sets for aircraft operating in Europe.

◆ NAAWS

NAAWS was canceled late in 1990, and efforts early in 1991 to restart the program appeared to have failed. Accounts of the reason for the demise of NAAWS vary. It has been blamed on U.S. reluctance to agree to further technology transfer (ironically, the purpose of NAAWS was to transfer Aegis technology to allied navies). There has also been a suggestion that there was no real willingness to pay for anything beyond the core system concepts worked out by the competitors. Further

NAAWS work would have involved expensive hardware, in the form of new radars and, ultimately, new missiles.

The main fall-out from NAAWS will probably be a number of new distributed CDSs, such as the Raytheon ICDS described in the Surveillance and Control section. Raytheon would have used a tail-controlled Sea Sparrow with a new and more energetic motor. Hughes clearly hopes to apply its work on display subsystems to the QRCC/SRAAWS program. The company had hoped to use a higher-power, extended-range variant of its AMRAAM missile as the NAAWS interceptor. Its team's multifunction radar was the GE/RCA FARS variant.

◆ QRCC/SRAAWS

With the demise of NAAWS, the former U.S. NAAWS project office is looking at an all-U.S. system built mainly from existing components, QRCC (Quick-Reaction Combat Capability). QRCC is to link existing autonomous hard- and soft-kill devices for greater effectiveness. This is a development of the RAIDS concept. For example, the RAM/Phalanx combination is being developed as a basis for a QRCC system. The computer that coordinates the 2 and passes Phalanx radar data through to the RAM mount can also accept SLQ-32 data and can in theory accept SAR-8 inputs. The computer can set and change jammer frequency and fire chaff.

In a larger sense, QRCC exploits the work that several U.S. NAAWS competitors did on weapons-system-oriented CDSs ("cores"). Like the Aegis CDS, these cores were intended as weapons-direction systems, grown up to handle further CDS tasks. As it happened, the rules of the NAAWS competition required the companies to develop Aegis-like cores without the associated radars.

Hughes is to mount a TPQ-36A Firefinder radar back-to-back with its prototype ITAS (the pedestal is heavy enough to take both). The result should be an X-band horizon-search radar mounted with an L-band volume-search set. The same pedestal will also support a Saab 700 FLIR. The sensors will be integrated through the ongoing TAS integration program. The system will use a Hughes-developed TEWA running on a UYK-20 (later UYK-44) computer (TAS Mk 23 now uses 1, and the double system would need 2). The display would be a standard UYQ-21.

SRAAWS (short-range AAW system) is an earlier term used for the U.S. equivalent of NAAWS.

◆ Antiaircraft Laser

At the March 1991 U.S. Navy League show, TRW displayed a model of an antiaircraft laser fitting within the envelope of a VLS "B" module. It is a repackaged version of the Sea Lite chemical laser that shot down a Vandal (converted Talos) drone missile at White Sands. The laser fuel (NF₃-ethylene-helium-deuterium) is carried in the module. To fire the laser, NF₃ is combusted with the ethylene to form hot fluorine, which reacts with deuterium to form excited DF, which lases. The laser itself is well below decks; the device above decks is the beam director, with a 1.5-m clear aperture (about as in the White Sands test). The model is far more compact than the White Sands installation because the latter used large steam-ejector pumps to compress the lasing mixture. In the module, 24 small jet engines are used instead. The laser exhaust is heavily diluted with air to make it less toxic; TRW claims that it is considerably less toxic than the blast from the vertical launcher module it replaces.

The TRW weapon is a CW laser; TRW chose CW over pulsed operation because the underlying technology is so much more mature. TRW also claims that, at least at the powers available, CW and pulsed lasers would both kill their targets mainly by heating and burning them (a very high powered pulsed laser might have almost a projectile effect, blasting a hole through its target). It is easier to shoot down a crossing than an approaching target because the laser beam slews as it tracks the crossing target. A beam pointed continuously in 1 direction

tends to bloom as it heats the air through which it passes; a slewing beam encounters no such problem.

As of March 1991, TRW claimed that it could build a test module at once, and that incoming missiles could be killed at roughly Sea Sparrow's range.

◆ Phalanx

In 1990 General Dynamics received a contract to develop and integrate a new and much faster Control Data AMP computer using R3000 RISC processors (and said to be 100 times as fast as the current unit) into Block 1. A further version, Block 1R-III, will incorporate some new radar components, including a Thomson-CSF transmitter and a new signal processor. RFPs for Block 2 FSD are expected (as of late 1990) late in 1991 or early in 1992, with contract award expected late in 1992 (and Block 2 entering service at the end of the decade). Block 2 is likely to entail additional sensors (EO/IR) as well as better accuracy, a higher rate of fire, and increased projectile energy (e.g., greater caliber). General Dynamics has awarded Oerlikon a contract to mount its new 25-mm Gatling 5000 gun (as used in the Italian Myriad) on a standard Phalanx turret. The Oerlikon gun differs from other Gatlings in that it carries its ammunition in a trough fixed to (hence elevating with) the barrel. The designation refers to its rate of fire, 5000 rnd/sec. Other candidates include Tround, the telescoped 25-mm Gatling, and a 4-barrel 30-mm GAU-13/A gun used in Goalkeeper.

Block 2 models shown at the March 1991 U.S. Navy League exhibition had their search radars moved to a separate pedestal. The tracker was retained atop the gun, but in place of the search radar was a pair of EO sensors (television and IR). General Electric was advertising a new 35-mm telescoped-case gun for Block 2 because the earlier 25-mm proposal would not have provided enough firepower (the smaller caliber is still proposed for other applications).

Block 1 is currently operational in the U.S., Australian, British, Greek, Japanese, and Taiwanese navies. Remaining operators of Block 0 are Canada, Israel, Pakistan, Portugal, and Saudi Arabia.

◆ ETC

The navy is studying an electro-thermal-chemical gun for point or area defense under the BTI program. In March 1990 it awarded contracts to both FMC and General Dynamics for cartridges for a new ETC gun, using a navy-supplied Israeli (IMI) 60-mm gun and recoil mechanism. FMC also has a contract for an autoloader, and as of early 1991, a further contract was to be let for the design of a smart projectile (SCSM, small-caliber smart munition). The FMC project is based on earlier work on CAP guns. General Dynamics had worked on ETCs for DARPA as part of the missile defense (SDI) program, using a 105-mm gun. The experimental 60-mm gun is to be mounted on a Phalanx trunnion assembly, and the total weight will approximate that of the Phalanx gun (less its radar, presumably).

The object of the experimental weapon is to achieve a useful high muzzle velocity without the violent acceleration associated with a conventional gun, and thus without damaging the heavy (up to 3.5 kg) smart projectile. The minimum acceptable muzzle velocity is 1 km/sec [3280 ft/sec], which is very high for such a projectile, and the actual velocity may be 2 km/sec or more (some other technology, such as a pure electromagnetic gun, would be needed to achieve or exceed 3 km/sec). The gun itself is 4.2 m long (70 cal), including its chamber (about 28 in, or 71 cm, long). The rate of fire should be comparable to that of a Bofors 57-mm gun, i.e., well over 100 rnd/min. Projectiles will be fired in bursts of 10 per target, and the weapon will be able to fire conventional as well as special ammunition. The original Israeli gun was developed for tanks and light armored vehicles.

Prototype cartridges are to be delivered in August 1991, and firing trials are scheduled for the end of 1992.

FMC is also considering an ETC version of the current 5-in/54, but only on an internal basis. The navy is currently com-

paring the merits of large and small calibers for this technology, also on an internal basis.

◆ Mk 105

Mk 105 target-acquisition consoles were installed on board the PHMs as an interim means of detecting and targeting enemy emitters. They were to have been replaced by ALR-66(V)6 (which was first evaluated in FY88), but that was done in only 2 ships (PHMs 4 and 6).

◆ SLQ-20

Seesaw II augments the shipboard-countermeasures capability of ships deployed to particular areas. It is a log-periodic antenna mounted on SPS-49(V)1 radar antennas, replacing their AS-2182/UPX IFF antennas. This device first appeared in 1968. Most surface combatants equipped with SPS-49 radars can carry it.

◆ SLQ-22/26

These old threat-reactive systems survive only on board a few carriers: SLQ-22 on board CV 61 and SLQ-26 on board CVs 59 and 67. SLQ-22 is an operator-controlled threat-reactive system, used with ULQ-6. SLQ-26 is an analogous automatic threat-reactive system, also used with ULQ-6.

◆ SLQ-32

The current upgrade is an improved UYK-19 with more memory (512k), higher speed (3 times), and an embedded hard disk. Current plans call for SLQ-32(V)3 to be installed on board all *Spruance*-class destroyers and for (V)5 (Sidekick) to be installed on board all *Perry*-class frigates.

At the 1991 U.S. Navy League show, Raytheon displayed an improved console (based on the unit developed for FDDS) that could be used for SLQ-32 but would also be suitable for a next-generation system. Unlike the current single-screen, monochrome, character-oriented (i.e., cursive or stroker) monitor, the improved console has 2 large, color, raster-scan screens and a big embedded processor. The new console uses the same display technology as the abortive FDDS console, with militarized Silicon Graphics architecture. It fits the same footprint as the existing SLQ-32 console. Raytheon would prefer to go to a new console similar to that introduced in the submarine CCS Mk 2, using a RISC-based computer (MIPS R2000, upward-compatible with R3000). The new console would retain the current UYK-19/UYK-64 display processor because the processor is so tightly coupled to the SLQ-32 receivers. Moreover, this arrangement would preserve the large software investment represented by the current system. At the same time it would be suitable for the likely next great advance in shipboard combat systems, a distributed combat system.

◆ SLQ-50

The next-generation replacement for this specialized terminal is to be a version of the E-Systems MIST (Miniaturized Interoperable Surface Terminal).

◆ SLQ-54

SLQ-54 is the next-generation shipboard countermeasures set formerly known as AIEWS (Advanced Integrated Electronic Warfare System). It is to combine the short-range defensive features of SLQ-32 with long-range precision ESM. The program is now being competed, and the navy hopes to put SLQ-54 in service by about 2000.

◆ Night Surveillance Sensor (NSS)

Martin Marietta displayed this covert surveillance device at the U.S. Navy League show in March 1991. It is a semisubmersible carrying a periscope, ballasted to show 1 or 2 ft of mast. The total weight is 250 lb; the total height is 5.5 ft (length 10 ft). The hull's outside diameter is 8 in. The endurance is 2 hr at 5 kt; the maximum speed is 6 kt. The guidance system can maintain a heading to within 1.5 deg. The sensor is a low-light-level

CCD television camera with a zoom lens (17.5–108-mm focal length), operating in the near IR. The vehicle carries a 10-W video transmitter and a 10-W radio data link. Potential markets include the U.S. Coast Guard for drug interdiction.

◆ **RBOC/SRBOC**

Users are Australia (the *C. F. Adams*, ANZAC, and *Perry* classes), Belgium (The *Wielingen* class), Brazil (the *Garcia* class), Canada (the *Annapolis* and *Restigouche* classes), Egypt (the *Descubierta* class), Germany (the *C. F. Adams* and *Bremen* classes), Japan (surface combatants, down to frigates), South Korea (frigates), the Netherlands (the *Tromp*, *Karel Doorman*, *Jacob van Heemskerck*, and *Kortenaer* classes), New Zealand (the ANZAC and broad-beam *Leander* classes), Pakistan (the *Brooke* and *Garcia* classes), Portugal (the MEKO 200 class), Saudi Arabia (the PCG and PGG classes), Spain (the *Principe de Asturias*, *Perry*, *Baleares*, and *Descubierta* classes), Turkey (the MEKO 200s), the United Kingdom (the *Invincible* class, Type 42 destroyers, and some Type 22 Batch 1 and 2 frigates), and the United States.

ANTISUBMARINE WARFARE

ARGENTINA

◆ **S-2E**

The Argentine S-2Es are being upgraded by Israel Aircraft Industries, which is providing a new avionics suite of unspecified origin. Presumably, the upgrade includes a new sonobuoy processor, a new ELINT system (presumably Owl), and a new radar. Given the Argentine experience in the Falklands, the S-2Es would presumably be used to detect targets for Exocet-armed Super-Etendards.

CANADA

◆ **CTS-36/CMAS-36**

C-Tech claims that CTS-36's MTBF is greater than 500 hr. The operator-selected frequency is 36 or 39 kHz; the range scales are 250, 500, 1000, 2000, and 4000 m (there are range rings at $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$ full scale). There are 5 discrete power levels: full, -5 dB, -10 dB, -15 dB, and off. The 450 (dia) $\times$ 910 mm [17.7 $\times$ 35.8 in] transducer has 540 elements (270 channels); the pulse length is 1–150 msec. In directional mode, 36 elements/sector are driven. There are 3 independent tracking channels. The Doppler filter resolution is 1.25 kt over ± 20 kt.

CMAS-36 is the mine- and obstacle-avoidance sonar installed (on an emergency basis) on the 3 Canadian warships sent to the Persian Gulf. It is optimized for shallow-water operations. It normally operates at 36 kHz (39 kHz optional). In surveillance mode it searches a 76-deg zone centered on the bow. There is also an ODT search MCC mode using a broad, depressed (30-deg) receiving beam. The color display is 1280 $\times$ 1024 pixels. The electronic beam tilt is continuously adjustable between +8/-24 deg. The source level is 223 dB. Pulse lengths are 0.2 to 15 msec. The transducer matches that of CTS-36, with 540 elements.

◆ **CSAS-80/CSS-80AS**

C-Tech's harbor-surveillance sonar competes with Saab's Bottle Cap and is entered in a current (1991) competition for a Swedish navy harbor-protection sonar (trials were conducted in the fall of 1988). This sonar was being considered by Kuwait just before the August 1990 invasion, and it is being considered by at least one Asian country. CSAS-80 uses technology similar to that in the C-Tech Omni sonars (CTS-36 and CMAS-36) to search a 6-, 12-, or 24-deg conical field that can be tilted 24 deg up or down. Targets are automatically detected and tracked, and static targets can be suppressed automatically. Range scales are 250, 500, 1000, 1500, and 2000 m.

The related CSS-80AS provides 360-deg coverage in a 3-deg cone that can be stepped through a vertical sector of ± 15 deg. It operates at 80 kHz (source level 211 dB, pulse length 1–20

msec). The range scales are 62, 125, 250, 500, and 1000 m. The transmitted beam is ODT (4 deg in the vertical). The received beam is 17 deg (adjustable to 3 deg) $\times$ 5 deg. The bearing resolution is 0.56 deg. The transducer can be up to 2000 m from the dry-end electronics.

CHINA

◆ **EAJ-1**

This Chinese antisonar and antitorpedo jammer for surface ships and submarines hovers at depths of 30, 60, and 100 m [100, 200, and 330 ft] and operates at 15–40 kHz. Dimensions are 118 $\times$ 800 mm (weight is 8 kg). EAJ-1 can be launched at depths to 200 m [660 ft].

FRANCE

◆ **Salmon**

Singapore bought this sonar, not the EDO 786, for the new *Victory*-class fast attack boats.

◆ **SS 312**

Thomson Sintra announced this new small-boat towed array in February 1991. Like the earlier SS 12, it is an adapted helicopter dipping sonar (HS 312). It is very light (3–4 tons in all) and can go almost twice as deep as Salmon (300 m vs. 170 m). Handling gear has been adapted from that developed for Salmon. SS 312 was proposed for the Coast Guard's small-boat sonar program.

◆ **Spartacus**

The Lacroix torpedo decoy weighs 50 kg (diameter is 130 mm) and carries 25 liters of bubble-generating material or pyroacoustic noise-generating material. It can reach a range of 50–200 m in less than 3 sec.

GERMANY

◆ **Marine Target Simulator**

This modified (and lengthened) Mk 37 torpedo was first shown by Honeywell Regelsysteme (Germany) at Defendory in October 1990. Development began in 1989, and it will enter service in 1991. Endurance is 4 hr at 8–9 kt and 1 $\frac{3}{4}$ hr at 12–15 kt; the device tows an array of transducers and hydrophones and carries transducers in its body.

JAPAN

OQS-3 is a license-built SQS-23; OQS-4 is a signal-processing upgrade. OQS-101 is a Japanese-developed, 3-kHz sonar roughly equivalent to SQS-26/53.

NETHERLANDS

◆ **PHS-32**

Two are being made to replace old EDO sonars on board the 2 Dutch *Tromp*-class destroyers.

NORWAY

◆ **SS 245 Series**

This is Simrad's current series of 24-kHz, preformed-beam, hull sonars, which operate in ODT, sector, or directional transmitting modes. There is also an MCC mode using a broad vertical transmitting and receiving beam. Transmission and reception beams are tiltable (+10 to -20 deg) in 19 steps. The 32 beams are interpolated to form 64 display beams on the 20-in raster-scan display. There are no staves. Instead, the transducer is an array of 7 circular 27-element parts, arranged so that the spot transducers form a checkerboard to generate a more even pattern. The transducers' dimensions are 432 $\times$ 280 mm (weight is about 300 kg). Versions are SS 245 (hoistable, no dome), SS 246 (hoistable, with GRP dome), SS 247 (fixed, with GRP dome), SS 248 (hoistable transducer and dome), and SS 249 (hoistable, with inflatable rubber dome).

◆ SS 304

The display is a 14-in, 6-color (3 for symbols, 3 for echoes), 512-line, raster-scan CRT (frame rate 50 Hz). The beam is 9×7 deg. The source level is listed as 232 dB, but the output power to the transducer is 4 kW.

◆ SU Sidescan Sonar

The British "Isles"-class OPVs also use this sonar.

UNITED KINGDOM

◆ ADS

As of February 1991, for the next-generation helicopter sonar, to be called ADS (Advanced Dunking Sonar), the British were to choose between Cormorant and FLASH. HELRAS, Osprey, and HIPAS were all rejected. Reportedly, the front-runners had been HIPAS and Cormorant, which were considered about equal on technical merits. However, FLASH represents Anglo-French cooperation, and it may, therefore, enjoy decisive political backing.

◆ Torpedo Presetters

Plessey Naval Systems is developing a family of torpedo presetters to supersede the current standard Mk 264, Mk 309, and ATLAPS (i.e., low end fully manual, semiautomatic, and fully integrated). All are capable of presetting all the current major lightweight torpedoes: Mk 44 and 46, Stingray, A244/S, and Murène. Likely designations are PMW 55, 56, and 57, respectively, but they had not been approved as of March 1991. The U.S. Mk 264 and Mk 309 panels are limited to Mk 44 and Mk 46 torpedoes. ATLAPS, developed for the Royal Navy, can preset the Mk 44 torpedo but not the Mk 46 (Mk 46 would require a new module; it can be developed and supplied if a customer requests it). It was intended primarily to support the Stingray torpedo but can also control the A244/S.

◆ Plessey Torpedo Launchers

Plessey Naval Systems is developing a new series of universal lightweight torpedo tubes (i.e., with connections for Mk 44/46, Stingray, A244/S, and Murène). The designations are PMW 53 (3 barrel), PMW 54 (2 barrel), and PMW 60 (1 barrel). The current Mk 32 cannot fire Murène without major modifications to accommodate the torpedo's different connectors.

PMW 49a is an export version of the Royal Navy's STWS 1. Current export users are Nigeria and Thailand.

◆ STWS 3

STWS 3's export designations are LWL 1 (lightweight launcher) and DMTS 90.

UNITED STATES

◆ BSY-2

BSY-2 is the first fully integrated submarine combat system, all the sensors, data processors, consoles, and weapons controls riding the same high-capacity Flexnet bus. The consoles can, therefore, be switched among all the command/control tasks; there is also a separate geosit (geographical situation, i.e., PPI) console. BSY-2 is the first application of the EMSP (UYS-2) signal processor, which has been used in development work since 1989. BSY-2 incorporates 25 display surfaces (10 two-screen combat-system display consoles, 3 command displays, 2 tactical-situation monitors), 3 beam-former cabinets, 6 EMSPs (UYS-2), and 3 data processors. It can fire 8 weapons at a time and can control 4 wire-guided torpedoes simultaneously.

BSY-2 incorporates a unique ASIC (application-specific) beam-former chip (40,000 gates using VHSIC technology), which is presumably needed to exploit the great sensitivity of the big wide-aperture arrays (WAA) on the submarine's flanks. Another critical electronic item is the outboard electronics (OBE), a signal conditioner mounted external to the hull. Because it reduces the data load into the internal signal processors,

the OBE reduces the hull penetrations (and overall structural footprints) for the various submarine sensors. OBE is important not only for the new *Seawolf* but also for *Los Angeles*-class submarines, which are very space-limited, fitted with the new WAA.

The data bus is Flexnet, a packet-switched, fiber-optic bus with a capacity of 50 Mbits/sec (1000 messages/sec).

All the system computers use militarized 68030 chips (often combined with 68882 math coprocessors on a single small board). System software is written in 6 series (threads); the submarine can go to sea without the full set (but also without some capability). Total software includes 2979 kslocs (thousands of software lines of code) of unique software. Through 1990 there was some question as to whether all of this software could be written in ADA because of the paucity of ADA programmers. That situation raises the question of just how wise the shift to ADA has been.

The standard console, CSDC (combat-system display console) has 2 high-resolution, raster-scan, color displays (it is the basis of the Librascope naval workstation series). It is the first high-resolution color monitor with magnetic compensation to have been shock-tested (September 1990). The software provides 6 tactical aids: automatic contact following/aided detection (ACF/AD), automatic contact correlation (between arrays), automatic aided contact classification, automatic TMA, recommended weapons presets, and operator alerts.

System design and development was conducted in 1985-88, followed by detail design work in 1988-90. As of early 1991, the bulk of the critical items in BSY-2 had been tested, and the system was entering limited production. The WAA will also enter service in stand-alone form as BQG-5; the first such unit is to go to sea in 1993 on board a *Los Angeles*-class submarine. It will use the same beam-former hardware, software, and display as in the integrated BSY-2 system.

◆ SQQ-89

As of February 1991, the following *Perry*-class frigates will not receive SQQ-89: FFG-10, -24, -27, -31, -34, -37, -51, -52, and -54. The following ships have already been fitted: FFG-8, -28, -29, -32, -38, -55, -56, -57.

◆ SQR-17 Versions

(V)1 4-channel processor displaying raw acoustics in A- or B-scan format, with hard copy in gram format. It incorporates an RD-420 14-track magnetic tape recorder.

(V)2 Upgraded version that can also process towed-array data. The tape recorder is upgraded (to RD-420A), and this version incorporates a digital multiplexer encoder/decoder (DMED) to convert 32 channels of towed-array-hydrophone data, plus own-ship course and speed and track-bearing data into high-density digital format for recording.

(V)3 New-generation version with FDALE (Frequency Domain Adaptive Line Enhancement) for better detection of periodic signals buried in broad-band noise. This version was the first fleet ASW processor to incorporate adaptive line enhancement.

A(V)1 and A(V)2 Sixth-generation systems (the first was SQS-54, 1969). They are totally integrated, with 8-channel receivers and 28-channel RD-420B tape recorders. They add DIFAR, DICASS, and VLAD processing. Capacity is 8 LOFAR channels or 2 DIFAR/DICASS channels. The computer can conduct TMA (MATE/MLE). The main acoustic data display (19-in, high-resolution, raster-scan screen showing grams plus integrated grams) is supplemented by 2 auxiliary 9-in video-monitor displays for selecting the proper operating modes. SQR-17A can operate with buoys (data received via either a helicopter data downlink or an ARR-75 receiver), and it can feed data to an ASW FCS or to a hull sonar.

SQR-17 succeeded the 2-channel SQS-54, which was introduced in 1969.

◆ U.S. Sonar Transducers

The following comparative data have become available:

Sonar	Transducer	Frequency	Staves	Dimensions (in)	Wt (lb)
SQS-4	AT-363	14 kHz	48	39.0 × 40.7	3500
SQS-4	TR-114	10 kHz	48	45.92 × 45.735	10,250
SQS-4	TR-115	8 kHz	48	64.5 × 53.149	11,000
SQS-4	TR-116	14 kHz	48	40.5 × 41.395	3,730
SQS-4	TR-255	8–10 kHz	48	56.7 × 49.6	10,000
SQS-10	AT-349	20 kHz	48	18.8 × 25.8	1000
SQS-11	AT-354	25.5 kHz	48	18.8 × 23.9	800
SQS-17	TR-166	12–14 kHz	24	19.0 × 35.75	
SQS-23	TR-208	5.0 kHz	48	100.5 × 63.0	
SQS-30B	TR-195*	10.0 kHz	48	24.375 × 32.5	
SQS-35	TR-229*	11.9–14.1 kHz	24	19.5 × 29.0	
SQS-35	TR-230*	8.08–8.8 kHz	24	12.0 × 15.0	
SQS-36	TR-204	13 kHz	24	19.0 × 35.75	
SQS-38	TR-231*	11.9–14.1 kHz	24	19.5 × 9.375	

Dimensions are diameter × overall height. Early transducers are all magnetostriction types. Asterisks indicate ceramic transducers. TR-166 is made of ammonium-dihydrogen-phosphate. TR-196, for SQS-17A, used redesigned inductors (3 in 1) and had a mounting plate (the overall height increased to 38 in). TR-195 (SQS-30B above) is the smaller-scale transducer used in SQS-4-series VDSs (SQA-10 fish and hoist). TR-204 is made of barium-titanite. TR-208/208A is lead-zirconate-titanate. TR-229 is the transducer used by both SQS-35 and SQS-38. TR-231 is the MCC (maintenance of close contact) part of the SQS-38 transducer, not the entire transducer. This list is not complete, but it does give some idea of relative sizes. SQS-10 and -11 have 2 independent sections, each of 48 staves, stacked vertically.

◆ Lightweight Sonar

About March 1990 NUSC New London conducted an evaluation of lightweight sonars for small Coast Guard patrol boats. As of late March 1991, the final report had not been released. The competitors were DRS/Sparton, Massa, and Sanders (presumably, a variant of the company's ALFS competitor).

The DRS/Sparton version, the company's Portable Lightweight Sonar (PLS), was shown at the 1991 U.S. Navy League show. It consists of a new portable lightweight sonar processor that can work with either a new dipper or with standard DICASS sonobuoys emplaced by patrol boat, helicopter, or airplane. The dipper is essentially an enlarged (double height) DICASS (SSQ-62) transducer using a different ceramic. The total weight of the shipboard system is less than 1500 lb, including the winch and other mechanical equipment (less than 650 lb).

The PLS dipper is a sprint-and-drift system rather than a true towed VDS. DRS claims that it can detect a small (Type 209) diesel submarine out to 10,000 yd in good conditions. The body can be dipped to 50–500 ft in depth and can operate in sea-states up to 4.

◆ Sonobuoy Processors (AQA series)

The data that follow come from a declassified 1972 document. They retain their value because they give an indication of early LOFAR/DIFAR procedures. None of these figures is likely to characterize current U.S. equipment (modifications since 1972 have been extensive), but they do give some idea of the factors involved in sonobuoy operation. To the extent that Soviet sonobuoy practice reflects the U.S. systems of the 1970s, these data may also describe current Soviet practice (as in the use of Type 75).

The processors in use in 1972 were AQA-4, -5, and -7 aboard P-3As (Deltic), P-3Bs, P-3B DIFAR Retrofit, and P-3C. The buoys were SSQ-41 (LOFAR omni) and SSQ-53 (DIFAR). P-3B DIFAR Retrofit and P-3C could each process 8 channels of acoustic information simultaneously on dual signal-data recorders (SDRs) and another 8 channels on the bearing-frequency indicator (BFI). P-3As and P-3Bs were limited to 4 channels. The

frequency ranges were as follows: AQA-4, 10–200 Hz; AQA-5, 10–300 Hz; AQA-7 and P-3B DIFAR Retrofit, 10–2400 Hz. The much wider range was associated with electronic, rather than hard-copy, processing. Electronic processing made available automatic line integration (ALI) for automatic target detection. Unlike the earlier processors, AQA-7 could also operate in multiple modes. The normal LOFAR range was defined as 10–300 Hz, and a processor could operate over either the entire range or over the high or low half. AQA-7 could also extend the frequency range by adopting a coarser setting, to 80–2400 Hz (or high or low halves). The integration times were as follows: normal, 80 sec; medium, 2.5 min; long, 5.0 min for the normal band (corresponding times for the extended band were 40 and 80 sec and 2.5 min). Two grams on each processor (2 AQA-7s on board a P-3C) were available for DEMON, a process for recovering LF signals from broad-band noise. The broad-band frequency range, 300–2400 Hz, equated to a modulated band of 2.5–75 Hz. In each case, data could be processed over half a band. As a measure of frequency resolution, it was assumed that a weak signal could be dominated by a stronger one within 0.8 Hz (6.4 Hz in the extended-frequency mode). In this case the bearing computer associated with DIFAR buoys would see only the interfering signal. Similarly, it would be unable to distinguish 2 signals of roughly equal strength within 0.2 Hz (1.6 Hz in the extended-frequency mode). In this case, the computer would yield a bearing equal to the vector sum of the 2 sources. Tests in 1970 showed that the version of SSQ-53 then in use could locate targets within about 13 deg, although buoys could suffer badly when swamped by strong shipping noise at CZ ranges. Because both buoys used point hydrophones, they automatically combined direct, BB, and CZ sound paths.

◆ Mk 114 FCS/Mk 53 Attack Console

Mk 53 Mod 4 is a further digital version of the basic analog Mk 53 console, incorporating a second embedded UYK-44 computer. It was developed by Ocean Technology Inc. (OTI) as part of the projected FF 1052-class ASW upgrade. The full upgrade would have included FFISTS, the digitized Mk 114, and the SQR-17A signal processor. FFISTS would have functioned as the surrounding combat system, but only the Mk 114 it fed could have launched weapons. The second UYK-44 was intended primarily to perform TMA, as in the later versions of Mk 116; the entire upgraded suite would have been analogous to SQQ-89, albeit less capable. Mod 4 also includes a second graphics generator that would have driven a remote monitor (e.g., a large-screen display) and would have accepted inputs from remote peripherals. Hull sonars would have been upgraded to SQS-53B configuration. With the demise of the *Knox* class, potential Mod 4 installations in the U.S. Navy are probably limited to the 8 ships of the class that are to be retained for training. Other U.S. ships with Mk 114 FCSs are unlikely to need the full Mod 4 capability because they lack towed arrays (an active hull sonar

imposes a much smaller processing load). However, there may be a substantial foreign market among navies that currently operate Mk 114 systems (the Pakistani navy has already shown interest).

No at-sea test of Mod 4 as such is planned (it has already been tested at NOSC). The prototype Mod 2 was to be tested on board the *Gridley* in the late summer or early fall of 1991. Presumably, further units will be installed on board the missile cruisers.

OTI developed much of the Mk 116 software. Mk 53 Mod 4 was conceived as a down-sized and modified equivalent.

◆ Librascope Submarine FCS

The Librascope Israeli submarine system was for a Gal-class modernization. Three systems were manufactured, but the Israelis began to cancel the program in 1987 as the system was nearing completion, reportedly for fear of jeopardizing the Dolphin program. The modernization program began about 1985.

◆ Photonics Mast

At the March 1991 U.S. Navy League show, Rockwell announced that it was teamed with Barr & Stroud to compete for the contract for a U.S. Navy nonpenetrating photonics mast (the other major competitor is Kollmorgen). The 2 companies are already responsible for a penetrating photonics mast for the new Australian Type 471 (*Collins*-class) submarines. The proposed U.S. mast will use Barr & Stroud masts, Rockwell being responsible for overall system integration and in-hull electronics.

◆ UYS-2 (EMSP)

As of late March 1991, the future of UYS-2 in the ALFS program (as compared to commercial signal processors) had not yet been settled. AT&T has delivered an SEM-E version of the processor to the P-3C UPDATE IV program, and its throughput is equivalent to 24 UYS-1s. The same software can run on either a 1-processor or a 6-processor version.

UYS-2 is a modular machine designed to accommodate changing technology. AT&T claims that it embodies 4 important advances: (i) graphical programming using a Very High Order Language that is written symbolically or pictorially; (ii) a true-data flow architecture, which can accommodate devices transmitting data at quite different rates; (iii) a distributed operating system, which does not require time-line programming and which automatically optimizes the computer's operation; and (iv) a data-networking device, which can support multi-sensor processing and sensor fusion.

UYS-2 is designed to be programmed in a navy-supported Signal-Processing Graph Notation (SPGN), a very high order language expressed in flow charts. Each chart consists of a series of primitives (operations) connected by data-flow arrows and affected by control arrays. Typical primitives are beam-formers, FFTs, FIR filters, normalizers, and thresholders. UYS-2 uses an ECOS (EMSP Common Operational Software) based on work begun at NRL about 1980. AT&T claims that this graphical technique offers a substantial reduction in initial programming costs and also a 6-fold reduction in software-maintenance costs. Coding is entirely separated from hardware details, so programs are easily transported from machine to machine (AT&T has successfully run programs written for the SEM-B version on the SEM-E version).

UYS-2 is built out of 7 kinds of functional elements (FEs), which are connected through a 16×16 Data Transfer Network (DTN). The DTN is unidirectional and asynchronous, with full access to and from each connected device, and no data flow blocks any other. It carries 32-bit words at a rate of 7 Mwords/sec (SEM-B version) or 10 Mwords/sec (SEM-E version). DTN can be supplied in various sizes: 2-16 ports, 8-64 FEs.

Other FE types are

- Scheduler, which assigns processing tasks to available processing resources. It initiates node processing, scheduling up to 8000 nodes/sec. Capacity is 65,000 queues and 32,000 nodes.
- Global Memory (GM), sized in 4- or 8-Mword (16-bit

words) modules built of 1-Mbit DRAM and ASICs (125,000 gates/device).

- Arithmetic Processors (APs), which execute the preprogrammed primitives residing in their local memories (and are, therefore, well adapted to the SPGN language). The APs work in 16- or 32-bit format at 84 MFLOPS (SEM-B) or 120 MFLOPS (SEM-E).
- Input/Output Processor (IOP), which accommodates up to 16 channels at a total of 5 Mwords/sec (16-bit words); it has a 1-Mbit buffer memory and, in the SEM-E version, a 68020-chip CPU with math coprocessor.
- Command Program Processor (CPP), a UYK-44 in the SEM-B version and a 68020 with math coprocessor in the SEM-E version.
- Input Signal Conditioner (ISC), which performs analog/digital and digital/analog conversions, filters, demodulates, preprocesses, and provides programmable input gain and bandwidth limitation. It contains a 16-bit VLSI signal processor capable of 7M fixed-point multiplications/sec.
- Data Processor (DP), the only element not yet completed. It is to be a user-programmable (ADA language) processor in the SEM-E version, with its own I/O capacity, using a 68020 chip with a math coprocessor.

A DTN can carry a number of APs, GMs, and DPs, fed largely by an I/O Processor and an Input Signal Conditioner and controlled by a CPP and a Scheduler.

The DTN has already been used as the basis of an integrated avionics/sensor fusion system for the YF-23 fighter. AT&T's point is that widely different sensors all need much the same sort of signal processing and that, once processed far enough, their outputs can all be used together. The UYS-2 variant in the YF-23 is responsible for 4 different sensor groups for all core data processing, data fusion, and data display. DTN is also the basis of both alternative avionics suites for the army's new light helicopter (LHX).

AT&T published the following list of requirements for the alternative ALFS processor to show why UYS-2 would be superior. UYS-2's requirements and AT&T's comments are given in parentheses:

- 8 analog/digital input channels with growth capacity to 12, plus a dipping sonar (UYS-2: 16 channels plus sonar; UYS-2 can grow to 32 analog/digital channels via programmable ISC)
- 1 dual-redundant 1553B bus, with growth to 2 (UYS-2: 2 dual-redundant 1553B buses)
- 2 Proteus Digital Channel (PDC) interfaces (UYS-2: 2 full-duplex PDC channels with growth to 4; 4 PDCs will support the 13-AP output of the P-3C UPDATE IV)
- An interface with the ARR-84 sonobuoy receiver (UYS-2: ARR-84 receiver, analog and digital)
- No data-link-transmitter interface; requires sync word for active ping (UYS-2: provides sonic gate and supports 8 channels for data-link transmission; compatible with LAMPS III)
- No requirement for a DC gate (UYS-2: supports DC gate operation for active sonobuoy; also supports sonar trigger)
- 50% growth capacity required (UYS-2 for ALFS is 3 APs and 2 GMs, expandable to 3 APs and 3 GMs, and ultimately to 6 APs and 3 GMs, to give a capacity of 720 MFLOPS and to equal 24 UYS-1s)
- A sampling range of normal DIFAR plus Nyquist (UYS-2: much greater)
- Sonar modes and concurrencies: requires 4 directional buoys (not clear whether DIFAR or DICASS) plus sonar (UYS-2: meets P-3C UPDATE IV requirement for simultaneous broad-band and narrow-band [CR, CPR, Vernier] processing; 16 processing paths per computer, and 16 analysis bands per path)
- Nonvolatile memory: no set requirement (UYS-2: 16 Mbyte, expandable to 24 Mbyte)

The P-3C UPDATE IV version uses 9 APs, 6 GMs, 1 IOP, and an ISC.

AT&T and NAVSEA PMS-412 are currently running a customer expansion program (CXP) to support UYS-2 in such programs as BSY-2, SQQ-89, ALFS, and SURTASS/LFA (low-frequency array). Tasks include development of new and revised SEM-E interface and memory modules for NTDS, high-speed channel, small-computer-system interface, nonvolatile memory, and 16-Mword bulk memory. Software is also being revised.

◆ Neural-Net Signal Processor

GTE is developing a neural-net sonar-signal processor in hopes that it will be a much less expensive VME-architecture alternative to a future UYS-2 upgrade.

◆ Tomahawk ASW Missile

At the March 1991 U.S. Navy League show, General Dynamics displayed a model of a torpedo-carrying Tomahawk, a possible replacement for Sea Lance. The company had proposed just such a weapon during the initial standoff-weapon competition more than a decade earlier. In each case, the issue was that the missile would arrive at the submarine datum some considerable time after the submarine had been detected. To be worthwhile, it would have to be usable out to CZ range, in which case it would have to reacquire the target. General Dynamics proposed to do that just the way a LAMPS helicopter would, with passive sonobuoys that the missile would monitor. At the time, it seemed unlikely that the missile could relocate the submarine using self-contained electronics. This time the signal processing can be much more compact. General Dynamics has a current contract with DARPA to develop automatic relocation techniques. Moreover, it is now using an active pinger with passive-buoy receivers; the missile can carry up to 24 A/3-size buoys (the buoys have also shrunk since about 1980). The proposed torpedo-carrier is a development of TLAM-D, the submunition-dispensing version of Tomahawk.

◆ Mk 48 Torpedo

In 1991 the GAO reported that Mk 48 averages a 75% hit rate during weapons training and accuracy tests.

◆ Mk 46 Torpedo

Mk 46 Mod 5A(S) is the shallow-water version. It is in production as of March 1991, development having begun about September 1989. As of March 1991, the new Mk 50 is so expensive (and, therefore, its production rate so slow) that many Mk 46 torpedoes are being modernized. Alliant, the manufacturer, claims that Mk 46 Mod 5A(S) meets the NATO 40-m minimum-launch-depth requirement. It can operate in both passive and active modes.

◆ Mk 32 Torpedo Launcher

At least 1 Mod 5 was delivered to the PRC, which will probably copy it. However, the PRC had difficulty copying the Mk 46 torpedo because it was built in imperial (ft-in) rather than metric units.

◆ TDAS

The Torpedo Detection and Alerting System was advertised by Rockwell at the March 1991 U.S. Navy League show. TDAS is a data processor applied to existing shipboard sensors to provide rapid warning after a torpedo has been launched. It can also use sonobuoys or a temporary towed array as the acoustic sensor. TDAS provides an audible alarm and displays a threat bearing, as well as enhanced audio and a LOFARgram display for rapid confirmation and classification of a threat after the initial warning. Rockwell claims that TDAS has already been tested at sea aboard both surface ships and submarines.

◆ Countermeasure C2 System

At the March 1991 U.S. Navy League show Magnavox announced that it was working with the U.S. Navy on a next-

generation countermeasure command/control system, plus the associated smart countermeasures, for submarine self-protection. Magnavox hopes to use cooperating expert system software working with the submarine signal processors and providing the commanding officer with situation assessment, threat assessment, recommendations, and rationale. The project began as a Magnavox private venture. At present it is a software package that can run on a variety of computers.

◆ Low-Cost ASW Weapon (LCAW)

As of April 1990 three countries (Germany, Norway, and the U.S.) remain in the PG 34 Program. The Norwegian and German alternatives are all rocket-thrown. The U.S. alternatives are the Lockheed LENS and a low-cost version of the U.S. Mk 46. Both would be tube-launched. The Mk 46 version will use some new technology to greatly reduce complexity and cost (target for unit cost is \$50,000). For example, the twenty-one circuit boards of the standard Mk 46 are reduced to a single board with greatly increased capability. The Mk 46 LCAW is closely related to a U.S. Navy-sponsored Mk 46 SLEP program. The failed General Dynamics LCAW proposal was for an unpowered gliding (downward-spiraling) device with a downward-looking sensor. It would have fired a charge downward while passing over the target submarine. This device was rejected as insufficiently proven.

◆ E 90

The Franco-Italian collaborative torpedo is to be designated E 90.

MINE WARFARE

IRAQ

At the cease-fire talks at the end of the Kuwait War, the Iraqis stated that they had laid about 1200 mines, of which coalition forces detected and/or destroyed at least 350 before the end of the war. None seems to have been the new types displayed in 1989. Iraq used Soviet-designed contact and bottom mines (reportedly magnetic-acoustic), plus Italian-supplied Mantas. All components of the contact mine were produced locally, but the electronics of the bottom mine were supplied by the Soviets. In addition, the Iraqis emplaced standard land mines atop poles as an anti-invasion measure on the Kuwaiti coast. It is not clear whether the Soviets supplied Iraq with any pressure mines.

NORWAY

The new MICOS MCM control system (for the new surface-effect mine-countermeasures ships) uses an SBC 3000 processor (using 80386 chips) and programmed in "C." Each Simrad ATC900 console has 2 SBC 3000 processors and a 20-in raster-scan screen. There are 6 consoles in the minesweeper version: commanding officer, dynamic positioning/navigator, officer of the watch, tactical, avoidance sonar, and mine-warfare officer (the dynamic positioning and OOW consoles are mounted together). All consoles are connected to a dual Ethernet, to which the mine-avoidance and echo-sounding electronics are also connected (the mine-avoidance-sonar console is connected directly to the avoidance sonar, not to the system bus). In the mine-hunter version, an ROV-control console is added alongside the tactical console, a separate detection-sonar console (for the TSM 2023 minehunting sonar) is added, and 2 mine-warfare consoles are added alongside an additional dynamic positioning console. The minehunting sonar is replaced by a detection sonar; there is no mine avoidance system (or console).

UNITED KINGDOM

◆ Demon

Demon is a camera minehunting video system used on board British Lynx and Sea King helos in the Persian Gulf. It is designed to detect moored mines close to the surface by means of a computer comparing light of different colors.

UNITED STATES

◆ SQQ-14

SQQ-14 is essentially UQS-1 with an added classification sonar, the latter reportedly copied from the British Type 193.

◆ AQS-20

AQS-20 is envisaged as an AQS-14 replacement, adding further sonars to -14's side-looking arrays. It will sweep out the entire volume of the water, from near-surface moored mines down to mines moored near the bottom and ground mines; it will also look ahead. A major technical issue, then, is how to handle the very large amount of sonar data the towed body will collect. The RFP is due out on 1 April 1991. Likely competitors are EDO/Westinghouse, Bendix, Raytheon, and Thomson-CSF.

◆ Pressure and Acoustic Sweeps

At the U.S. Navy League show in March 1991, EDO displayed a photograph of an internally developed helicopter-towed bag pressure sweep. The bag would fill by ram pressure as it was towed. This basic approach has been tried, unsuccessfully, before.

There was an attempt to use 2 PHMs in tandem to create a shiplike pressure pulse, but unfortunately the PHMs were vulnerable.

In the early 1980s NAVSEA tried HIPAM, a pressure-acoustic-magnetic sweep.

Acoustic sweeps are currently a problem because all the U.S. noisemakers are speed dependent and, therefore, must be towed

The Operations Room (CIC) aboard HMCS *Halifax*, with the standard multifunction displays of the SHINPADS system. (Paramax)

Cage Flask (with Top Plate and its IFF in the background) on board a Soviet *Sovremennyy*, 1990. (H. J. Verhoefen)

at fixed speeds to be effective. The other likely future U.S. programs are rapid shallow-water mine clearance (for the marines) and buried minehunting. At present the only means of rapidly clearing a path through shallow water is a line charge (fuel-air explosives were a possible alternative).

◆ Trident

Due to the shut-down of plutonium processing and production at Rocky Flats, there are sufficient W88 warheads for only the first 2 *Ohio*-class submarines armed with Trident II (D-5) missiles. Until production is resumed, probably in 1992, W76 warheads (as on Trident I missiles) will have to be mounted on the D-5s.

A Soviet "Krivak" shows, from the top, Salt Pot (IFF), Hour Glass, and Headnet C radar. The small radome at the lower left is Shot Dome; on the right is Cage Flask and a pair of Cage Bare. (H. J. Verhoefen)

Trawl Net (on the right) on the mainmast of a *Sovremennyy*. (H. J. Verhoefen)

A *Sovremennyy* shows Cat Cage next to her Palm Frond surface-search radar on her yardarm. (H. J. Verhoefen)

Pole Star is the array at the extreme left. The radar is Palm Frond; the original of this photo shows a set of dipoles, presumably for IFF, on its feed. (H. J. Verhoefen)

The Helstar naval UAV. (IAI)

The Hughes OJ-663/UYQ-21 display console. The screen shows typical windowing. (Hughes)

The warhead of an HY-2 missile. The hollow of the shaped charge is clearly visible at left. (*Missiles and Spacecraft*, PRC)

The arrangement of the HY-2 missile: (1) radar seeker, (2) fuel tank, (3) shaped-charge warhead, (4) oxidizer tank, (5) auto-pilot, (6) terminal homing electronics, (7) booster, (8) sustainer rocket motor. The related C201W carries its terminal homing electronics in place of the oxidizer tank of HY-2; the turbojet takes up the after electronics compartment. (*Missiles and Spacecraft*, PRC)

A C101 missile in flight. (CPMIEC)

C201W, showing the turbojet air intake under its body. (CPMIEC)

C601 under the wing of a PRC Badger (B6D) bomber. (CPMIEC)

C801 next to its shipping and launching container. (CPMIEC)

C802, showing its underbody air intake. (CPMIEC)

ARMAT antiradar missiles carried by a French Air Force Mirage 2000 (the smaller weapons are Magic 2s). (MATRA)

Standard French air-to-surface weapons on display at Bourget Naval 1990: AS 30L is in the foreground, and the lighter AS 15TT is behind. Note the laser-seeker window in the nose of the larger missile. As of February 1991, AS 30L had already been used in Desert Storm. (Author)

ANS at Bourget Naval 1990. (Author)

A MATRA BGL 1000 laser-guided bomb in action; note that the bomb approaches horizontally. (MATRA)

Durandal. (Author)

Marte Mk 2, with an underbody booster allowing launch by a hovering helicopter, displayed at Farnborough in 1990. (Author)

Penguin Mk 7 Mod 2, with a competitor, Sea Skua, in the background at left in 1990. The helicopter is a Lynx. (Author)

HARM in 1990. (Author)

A pair of Sea Skuas on standard rails alongside a Lynx helicopter in 1990. (Author)

Rockeye, with bomblets just visible in the cut-away section at the nose. (Author)

A marine AH-1 helicopter carries Sidarm, a pair of Hellfires, and a standard rocket pod in 1990. (Author)

RDY radar; the small dipoles are for IFF. (Thomson-CSF)

Sea Owl on the nose of the prototype Lynx HAS.8 helicopter in 1990; the spiral antennas of Orange Crop are below Sea Owl, and the radome of the Seaspray radar is below the nose. [Author].

Texas Instruments's expendable decoy (GEN-X). [Author]

A typical ISAR image. (Texas Instruments)

Texas Instruments's model of a head-steered FLIR (i.e., slaved to the pilot's helmet), displayed at the 1991 U.S. Navy League show. It would be valuable for off-centerline target detection and recognition and would have 2 FoVs. A prototype has been flown over 100 hr in various mission profiles. A FLIR of this type could do away with the requirement for night-vision goggles for off-axis viewing. [Author]

A TALD decoy, with its wings folded, on display at Farnborough in 1990. The poster at left shows the Brunswick proposal for a powered ITALD, the intake for which would be below the device's body. [Author]

AS-9 antiradar missile. Note the strong family resemblance to the much larger AS-4 and AS-6. This example was displayed in Baghdad in 1989. The missile in the background is Nissan-28, apparently a Soviet-supplied AA-7 mocked up to simulate an antiship weapon.

AS-10, with a large-caliber unguided rocket to the far left.

AS-11.

AS-14.

The Hughes/McDonnell Douglas version of AIWS shows folding tail fins and angled sides for minimum direct radar reflection. The missile below is the Raytheon-Hughes version of AAAM. (Author)

HARM Block IV seeker head, displayed by Texas Instruments at the 1991 U.S. Navy League show. The object in the background is a radar antenna through which a missile of this type had passed, signed by the members of the development team. Note the spiral antenna in the missile's nose. (Author)

Boeing's version of AIWS, displayed at the 1991 Navy League show. (Author).

The Texas Instruments/LTV version of AIWS, displayed at the 1991 Navy League show. (Author)

The Martin Marietta version of the Advanced Bomb Family, as displayed in 1991. The bomb control units would be inserted to provide inertial guidance. (Author, from a Martin Marietta poster)

The McDonnell Douglas version of a 500-lb Advanced Bomb Family bomb. (Author)

BLU-109/B hard-target penetrator, used extensively against Iraq. (Lockheed)

WEIGHTS (LBS)

PENETRATOR	44.4
GUIDANCE KIT	258

TOTAL WEIGHT	4672
--------------	-----------

GBU-28 hard-target penetrator, used at the very end of the war against Iraq. It went from concept to use in only 22 days. (Lockheed)

A typical armor-piercing slug formed by a modern bomblet, in this case a Sensor Fuzed Weapon, i.e., a bomblet that explodes at a standoff from its target (the object is cut away to show its cross section). The 3 pieces of metal represent stages in the formation of the slug, and the armor plate shows what it can do. This is a modern shaped charge, using very little cone angle to produce a very considerable effect. This type of technology in turn makes for smaller bomblets, more of which can be packed in a standard-size dispenser. This weapon was displayed by Textron at the 1991 U.S. Navy League show. (Author)

The Naval Research Laboratory (NRL) displayed this multiservice decoy (MSD) at the March 1991 U.S. Navy League show. It is a towed airborne decoy developed in response to a 1987 request by the JAEDO (Joint Air Expendable Decoy Office). It has been under flight test since 1988 to explore both decoy aerodynamics and overall system effectiveness.

MRR, the successor to Triton, as shown at Bourget Naval in October 1990. The upper antenna is IFF. (Author)

The operating principle of the Volcan IRST. (SAGEM)

The two smaller members of the Volcan family, VIGY 50 and SAS 90 (left and right) in 1990. The base of a Volcan is just visible at upper left. (Author)

The Japanese FCS 2-12. (*Ships of the World*)

MW-08 on board the new Portuguese frigate *Vasco da Gama* in 1990 (Signaal)

The MR 05 antenna. (Signaal)

SCOUT, the new Signaal stealthy radar. (Signaal)

SMART. (Signaal)

A LIOD optronic director carrying a daylight television, FLIR, and laser range-finder. (Signaal)

LIROD, the radar version of LIOD. (Signaal)

STING, Signaal's missile-tracking system, shows a laser range-finder, a daylight TV camera, and a FLIR camera at left, in 1990. (Signaal)

Gemini carries the X-band acquisition radar developed for Goalkeeper (the long slotted array) and a Ka-band tracker (as in LIROD) as well as a laser range-finder in 1990. The director can also carry a FLIR. Gemini has not yet been sold, but apparently it is now being marketed in container form. (Signaal)

Head Net C with Hour Glass atop it on board a Soviet Krivak-class frigate, 1990. (H. J. Verhoefen)

Plate Steer. Note the 2 waveguides feeding the antenna at left; the larger (lower-frequency) of the 2 extends back up to the IFF array at right and is presumably used for IFF by both antennas. The characteristic serpentine feed of a frequency-scanning radar is visible on the outer edge of the right-hand antenna. Note that the array is not vertical.

Plate Steer.

Mad Hack. Note what appear to be arms to lift the flat plates; they may well be covers for some device inside the deckhouse rather than antennas of any sort. The top plate lacks the darker-colored pattern of the side plate, which may have been intended to simulate an antenna.

Bass Tilt.

Drum Tilt radar at the masthead of the former East German training ship *Wilhelm Pieck*, which was visiting London in 1990. The slotted arrays are the standard TSR-333 used on board many East German warships. (B. Sullivan)

Front Door/Front Piece on board a *Slava*-class cruiser, with what appears to be a surface-search antenna mounted directly atop it. This small antenna is presumably used to acquire the beacon signal from the missile. The larger surface-search radars are Palm Fronds.

Head Lights. The circular shape of the feed on the left suggests a vertical scan rather than a monopulse cluster. The barely visible but apparently cylindrical feed of the other antenna appears to be horizontal. That would suggest that, like Peel Group, this director scans separately in elevation and in train (using the far-side antenna for that). In that case it continues the TWS technology of the earlier systems, each pair of antennas (large and small) constituting a single TWS unit.

Owl Screech, showing the characteristically canted cylindrical feed and the opening in the antenna for an EO camera.

Peel Group.

Pop Group.

An optical director on board a *Sovremennyy*-class destroyer, 1990. (H. J. Verhoefen)

Top Knot (TACAN equivalent) on board the Soviet carrier *Kiev*, with Top Plate in the background and Vee Bars long-range communication antennas.

Fly Traps for carrier-controlled landing, these devices appear on board Soviet carriers and helicopter-carrying surface combatants.

The *Kiev* shows a pair of SA-N-3 missiles on her after launcher. They appear blunter than they are because the dark nose radomes blend with the ship's superstructure. Note the 2 elevated dishes (missile trackers) of the ship's after Head Lights missile director. The small radomes alongside the lower one of the upper pair of Side Globes are Bell Bashes; the lower pair (not visible here) is associated with Bell Thump.

NAJIR Mistral displayed at Bourget Naval, October 1990. (Author)

Sadral, the 6-missile automatic Mistral launcher. Note atop the launcher the optronic sensor that acquires and tracks a target before the missiles are fired and in front the doors that protect the missile seekers before launch. The missile tubes are removed whole for reloading (note the straps atop the tubes at right). (Author, 1990)

The Crotale NG launcher (left, with the optronic sensor mounted between the 2 banks of missile tubes) and its associated CTM radar/optronic director (right), as displayed by Thomson-CSF at Bourget Naval, October 1990. (Author)

The VT1 missile of the Crotale NG system in 1990. (Author)

The Mauser Vierling CIWS gun. The Mauser Vierling is also now being called Taifun. First sea trials (1991) will be run with a modified Bofors L70 mounting. An entirely new mount should be ready in 1993. Meanwhile, the German navy is leasing Goalkeepers as interim replacements for the RAM missiles planned for its frigates. (Mauser)

A pair of SA-N-3 missiles are shown on their rails on board a Soviet Kara-class missile cruiser, with their Head Lights fire-control radar visible between them. The large tubes are for SS-N-14 ASW missiles.

A standard Soviet twin 130-mm mount.

Soviet twin 30-mm (AK-230) mount. Presumably, the tub at right is for local control.

The FMC ETC gun being developed as a possible future close-in defensive gun. (FMC)

Raytheon's version of a modified *Perry*-class frigate shows its C-MAR phased-array radar (above the bridge and abaft the mast; the forward faces are incorrectly marked "ESM/ECM" because the SLQ-32 is abreast the forward phased-array block). The Mk 74 MFCS replaces the Mk 92 "egg" and STIR of the standard U.S. frigate. This is presumably the version that Raytheon has proposed to Taiwan for its eighth *Perry*-class frigate. (Raytheon)

General Dynamics's Sideshooter proposal: two 21-rnd RAM launchers alongside a 5-in/54 mount (the third launcher, visible above the gun mount, is separate). (Author)

AIM-7R and RIM-7R will have both IR and semiactive radar seekers. This is the nose of an AIM-7R Sparrow, displayed at the March 1991 U.S. Navy League show. (Author)

A model of SM-2 Block IIIB at the March 1991 U.S. Navy League show has a bulge forward for its IR sensor (visible on the right-hand side of the missile). The square objects visible near the tail are clips for the launch rail. (Author)

The General Dynamics/Westinghouse version of AAAM. Note the vectored-thrust controls in the booster and the strong family resemblance to the Standard Missile. (Author)

The Hughes/McDonnell Douglas version of AAAM, showing folding tail fins for tighter packing. (Author)

The General Electric version of Phalanx Block II, using a 35-mm telescoped-case gun. Note the separate tracking radar and the slit for 1 of the electro-optical sensors atop the tracking radar. (Author)

A General Dynamics Phalanx Block II concept using twin 25-mm telescoped-case guns. (Author)

General Dynamics models of possible Phalanx Block II guns, with the radar/EO dome removed to make them clearer. The model on the left shows the Oerlikon 25-mm gun. On the right is a 6-barrel Tround. (Author)

DAGAIE Mk 2 in 1990, showing the SAGAIE tubes between the standard "suitcases." (Author)

SAGAIE in 1990. (Author)

TRW's model of a shipboard air-defense laser, displayed at the March 1991 U.S. Navy League show. The beam director is at the left, the exhaust stack at the right. The tubes just to the right of the beam director contain the fuel. The entire system occupies the same space as a VLS launcher. (Author)

Current and future French decoys in 1990: at left is the SAGAIE IR decoy, and at right the new active decoy (LAD, *leurre actif decalé*). (Author)

A standard Soviet twin chaff launcher.

SLQ-32(V)2 (above) and Sidekick (below) on board a *Perry*-class frigate. (Raytheon)

Raytheon's Advanced Electronic Warfare Console, as displayed at the 1991 U.S. Navy League show. (Author)

WLQ-4 under test and installed on board a submarine (looking aft on the outboard side). By the time production of the basic version had been completed in 1987, 43 had been made for use on board SSN 637-class submarines. A modified version will equip the new *Seawolf*. WLQ-4 automatically searches the assigned portion of the spectrum, acquires, and processes signals. Reporting, logging, and bookkeeping are all automatic. Real-time-measured data is semiautomatically fused with external system inputs. All of this requires 400,000 lines of UYK-20 code plus 50,000 lines of executable code in 40 microprocessors. (GTE)

The Brunswick KAS-1 laser, chemical-warfare directional detector (CWDD) uses a common-module, 60-element FLIR (with 2 FoVs). It is the U.S. Navy's current standard standoff nerve-gas detector. A comparison of images in the filter's 3 bands is used for gas detection; the FLIR can also be used for night surveillance, navigation, and search and rescue. FoVs are 3.4×6.8 (resolution 0.40 mrad) and 1.1×2.2 (resolution 0.13 mrad) deg. Minimum resolvable temperature is 0.3 deg at 3 cycles/mrad, 6 lines/m at 1 km. The sensor weighs 28 lb (plus 18 for the power control unit). (Author)

Martin Marietta's Night Surveillance System (NSS). (Author)

McDonnell Douglas and Hughes launched their first advanced interception weapon system (AIWS) on 10 December 1990. The AIWS is designed to replace current standoff weapons such as Maverick, Skipper, Walleye, and laser-guided bombs. (McDonnell Douglas)

A Soviet Victor-III-class submarine displays her towed array pod atop her vertical fin. This particular submarine had fouled the towing cable of a U.S. towed array, and her crew was trying to break the cable. The submarine was trimmed down by the bow, so her unusual double propeller (two 4-bladed propellers in tandem, turning together) is visible. This type of propeller was adopted by many early steam-torpedo and destroyer builders as a way of transmitting considerable power without cavitation and without accepting unduly large propellers. The scale of the pod and fin are clear from the figure of the Soviet crewman trying to cut the cable. This photograph was taken in the fall of 1983. [U.S. Navy]

The DRS/Sparton lightweight shipboard dipping sonar, on display at the 1991 U.S. Navy League show. The electronics are at left (note the use of a laptop computer for system monitoring and control, with the larger screen reserved for the system display). At the right, the dark cylinder is the dipping transducer, with a DICASS buoy next to it for comparison. (Author)

Librascope's multifunction console for the Australian *Collins*-class submarine combat system. (Author)

DRS's SQR-17A console. (Author)

Raytheon's CCS Mk 2 console, which the company hopes also to use for its new integrated combat system. (Author)

Martin Marietta displayed its RMES (reconfigurable multiline array evaluation system) at the March 1991 U.S. Navy League show. Long and short arrays can easily be plugged into the fish to form horizontal or vertical or crossed arrays. (Author)

Martin Marietta's HIPAS (high-performance active sonar) sonar transducer, a candidate for the U.S. ALFS (advanced low-frequency sonar) program, for the British ADS (advanced dunking sonar), and for the Canadian APTS (acoustic processor tethered sonar). The flextensional transducer (the active transmitter) occupies the centerline of the dipping body, inside the framework. The receivers are on 2 sets of umbrella-like struts, 10 at the top and 10 below, with 4 spot transducers on each strut (for a total of 80). Martin Marietta claims twice the usual direct-path range (probably 20,000 yd), plus BB and CZ capability. Presumably, HIPAS operates at 3 kHz or below. HIPAS is designed for rapid (30 min) installation. It probably uses fiber optics to carry its 80 signal channels from dipping body to processor, and the signal processor is the Martin Marietta advanced systolic arithmetic processor (ASAP). (Martin Marietta)

USSR

The information given here is taken from a new monograph, A. de Sam Lazaro, *Soviet Electronic Warfare* (Washington, D.C.: Delphic Associates, 1991). Captain de Sam Lazaro served in the Indian navy in 1963–83, operating Soviet-supplied ships (ultimately, he commanded a Nanuchka squadron) and attending Soviet naval schools. He was executive officer of the Osa-class missile boat that sank the Pakistani destroyer *Khaibar* during the 1971 Indo-Pakistani War.

◆ Data Link

A short-range data link was introduced about 1973–74 to transmit a ship's radar picture to a command ship within a group. Doctrine was then being formulated. The link was to be used continuously in an air-threat environment but only intermittently in a surface-threat environment (when the radar picture would not change as rapidly). This system operated on much the same frequency as local television stations, presumably VHF/UHF.

◆ Styx Missile (SS-N-2; P-15, P-20, P-21)

P-15, P-20, and P-21 are different missiles despite their common NATO designator. P-15 (SS-N-2A) uses a barometric altimeter and, therefore, cannot approach a target at very low level (cruise altitude is 150–300 m); it dives toward its target at a 19-deg angle. P-20 (SS-N-2C) uses a radio altimeter and cruises at 25–50 m. P-21 (SS-N-2D) uses a Doppler radio altimeter, which reduces missile drift in altitude during flight. It cruises at a 25-m altitude. P-21 also has an IR seeker. All have a diameter of 750 mm, but P-20 and P-21 are considerably longer (6.55 rather than 5.8 m) and heavier (2600+ kg compared to 2300 kg). The P-15 warhead weighs 454 kg; that of the later missiles weighs more than 500 kg. Range is increased from 40 km in P-15 to 80 km in P-20 and to 100+ km in P-21. The claimed single-shot hit probability of P-15 was 0.72 and about 0.63 for the longer-range P-20 at maximum range. The original fuel was kerosene, oxidized by fuming nitric acid. Current P-20/P-21 missiles have a different combination for greater range.

Construction is modular, with standardized parts (such as gyros, power supplies, and waveguides). The policy is repair by replacement: a seeker head can be changed in 10 min without removing the missile from its tube.

The oldest surviving Styx seeker is MS 2, which was originally used by all versions. It seems likely that the original Styx used an earlier conscan seeker, presumably MS 1. The current seeker in P-20 and P-21 missiles is MS 2A, which has 4 horns and scans on receive only (but is not a true monopulse set). Some MS 2 and MS 2A ECCM features were retrofitted into Styxes supplied to India and Iraq in the early 1980s.

The vacuum-tube version of MS 2 was introduced in the early 1960s. By 1969 it was in its 8th version; much effort had gone into increasing the peak power and making the range gate flexible enough to ensure capture of a target at the designated distance (i.e., allowing for target movement during the missile's flight). The computed hit probability at this time was 0.72. Captain de Sam Lazaro reported that Indian modifications to the seeker were later adopted by the Soviets and passed to Algeria and Iraq.

The condition for lock-on is that the radar receive echoes from 8 consecutive pulses. The closer it gets to the target, the greater the apparent angular motion of the target. If the missile tracks the target all the way in, it tends to hit aft (to chase the target, in effect). The Soviet solution was to bias the missile away from target motion at the very end of its flight, using what was called a throw-off gyro, which took over control when the missile was within a minimum range of the target. The early version was designed to activate when received pulses rose above a set strength. Because that rarely happened, early P-15 missiles generally made stern hits. Later missiles use a throw-off gyro that is continuously realigned during flight to lead the target. Gyro angle is compared to a correcting vector generated by the missile's autopilot. When the 2 angles match, the throw-off gyro is released so that the missile hits the target broadside-on.

The range gate is about 1 km on either side of the target. Attempts to halve the range gate and to introduce home-on-jam were unsuccessful. Seeker PRF is manually adjusted and can vary considerably from missile to missile. Typical base missile PRFs might vary between 400 and 600 pps. Superimposed on the base PRF is a 100-Hz random wave that jitters the PRF. Feedback in the range cycle causes the transmitter to increase

The Martin Marietta HIPAS transducer, shown folded and unfolding, at the 1991 U.S. Navy League show. (Author)

General Dynamics's proposed torpedo-carrying Tomahawk, at the March 1991 U.S. Navy League show. (Author)

Japanese mine-destruction charges used with the S-4 and S-7 ROVs. (*Ships of the World*).

base PRF as the missile approaches the target. Variable PRF is intended to make it difficult for a jammer radiating into the missile's sidelobes to pull off the range gate. Because the jammer is not in the missile's line of sight, the jammer must simulate a target there by locking into the seeker's PRF pattern (the seeker cannot tell where the sidelobe radiation originates). In this case, outbound-range-gate stealing, the missile rejects jammer pulses at the wrong PRF. The missile can still be confused by a range-gate-stealing decoy that is in its line of sight, however, because in that case PRF matching is not needed. It turned out that a large and sudden variation in PRF often confused the seeker's receiver. Thus a later version of the seeker uses a more stable PRF.

The Indian Defense Research and Development Laboratories (DRDL) at Hyderabad modified the seeker to shut down if it received what it recognized as a jamming signal, the tracker remembering the last measured rates. A deception transmitter about 100 MHz from the seeker's frequency was activated to confuse the jammer. The real tracker would then transmit in short bursts to confirm and correct the rates.

Styx tactics were designed to reduce a target's jamming opportunities. The FCS was intended to compute a course so that the missile would fly on autopilot until it was about 3.5 nm from the target's computed position, giving just enough time for the missile's seeker to receive its 8 pulses and lock on.

After the 1971 war with Pakistan, Indian (and Soviet and probably other) MS 2 seekers were modernized with solid-state electronics, greater peak power, 2 additional magnetrons (for pulse-to-pulse frequency agility), and a phase-sensitive receiver (presumably for MTI). These changes were incorporated in the new MS 2A seeker, first supplied to India in 1975. MS 2A was further developed after 1975. The current version is PRF-agile (the 100-Hz AC is superimposed on a PRF that varies continuously with range). Moreover, the receiver opens only for selected pulses, so it automatically rejects some jamming pulses. That probably counters most inbound range-gate-stealing techniques. MS 2A also has passive (home-on-jam) modes.

During the late 1970s and early 1980s P-21 missiles were fitted with auxiliary IR seekers in a bulge under the nose of the missile. The missile switches to IR mode when its seeker is jammed; it begins a search pattern and locks onto the hottest IR source it can see.

In the Indian navy, Osas carry P-15s, but Nanuchkas and Kashins carry P-20s (Kashins also carry P-21s). A Nanuchka cannot fire P-21s because of limitations in its test system. Captain de Sam Lazaro indicated that Styx has been copied by India and perhaps by Iraq. He recalled a price of only \$20,000 per missile, presumably about 1980. This may be the cost of manufacture in India.

NAVAL RADARS

MR in Soviet radar designations means *Morskaya radiostantsiya*. The radars described below (and also the Styx seeker described above) all incorporate a manually tunable cavity resonator (an *ekho-kamera*) in their waveguides to protect the set against jamming signals slightly off the radar's operating frequency. The resonator also limits the amount of energy that can pass through it, so it grounds out large spot-jamming signals that might otherwise enter the receiver (and that would burn out the TWT preamplifier). Square Tie, Drum Tilt, and Muff Cob all share the same TWS mode of operation, although the 2 GFCS radars do have an additional fine tracking mode for air targets. Finally, the Soviets' official insistence on avoiding WARM modes in peacetime, i.e., on limiting all radars to a single operating mode, does cause some interference problems. Presumably, they worsen considerably as more ships spend more time operating together.

◆ Square Tie (Rangout)

This radar operates in X-band at 2 alternative power levels (20 and 100 kW); the displays are a PPI and a B-scan. The gyro-stabilized antenna scans at 4 or 12 rpm (the stabilizing device is a

bellows presumably similar to that used by Contraves in Sea Hunter 4). There are 4 preset frequencies, each of which can be tuned through ± 10 MHz; the frequencies are normally set about 10 MHz apart. The receiver uses a tunable TWT preamplifier (i.e., an approximately 10 dB amplifier inserted between the antenna and the relatively noisy superheterodyne receiver proper). The Soviet designers of the set believed that weak signals might well exceed the external noise and clutter and yet still be swamped by receiver noise unless they were amplified first. Captain de Sam Lazaro claimed that this technique so improves the signal-to-noise ratio that Square Tie can detect a target with about half the peak power of a comparable Western set. However, it can be quite difficult to tune the TWT amplifier, particularly under conditions of radar silence. Moreover, particularly strong signals can burn out the TWT (he recalled several such cases in the Soviet fleet).

Square Tie can normally detect a carrier or tanker beyond 30 nm (the maximum instrumented range is 40 nm). However, in parts of the Black Sea and the Indian Ocean (particularly the Persian Gulf and the North Arabian Sea) there is often a duct extending about 12 m above the surface. Some of the Indian navy's Square Ties (on board Nanuchkas, where they are low enough to take advantage of ducting) have been retrofitted to increase their instrumented range to 60 nm to use this atmospheric condition (at high power level, Captain de Sam Lazaro recalled detecting a Kashin at 55 nm). The antenna is gyro-stabilized. This radar is connected to an electromechanical fire-control computer, a KLEON in Soviet parlance. Targets are designated to the computer by means of a *vilka* (fork) and a movable range marker, both controlled by the operator's joystick. As in many other auto-track systems, 2 consecutive detections suffice for auto-tracking to begin. Typically, the radar is turned off once the computer has calculated range and range rate; it is turned on only intermittently to check the accuracy of the tracker. The FCS is designed to accept intermittent data so that the radar need not radiate continuously (it has a dummy load for use when not radiating).

The typical tuning time at sea is 3 min when the radar is in a standby mode and up to 10 min if the set must be warmed up first. A set can remain on standby time for only a limited (unspecified) period.

◆ Drum Tilt (MR 104)

This X-band search and FCS radar operates at X- and C-bands with a peak power of 100 kW. In search mode it covers the entire horizon and elevations of 0–40 deg. The maximum tracking range is about 23 nm, though targets have been detected at 35.5 nm under some conditions. The gyrostabilizer limits continuous running time to about 4 hr. The electromechanical MR 104 computer limits the system to targets closing at up to 400 kt. The warm-up time is 5 min (mainly to run up the gyrostabilizer), and MR 104 cannot run continuously for more than 4 hr. Although the radar normally scans automatically, it can be made to stop and radiate in 1 direction (Captain de Sam Lazaro recalled Soviet sailors often used this mode to cook sausages held in front of the radar).

The transmitter is located directly under the nacelle to minimize waveguide losses (albeit at a cost in reliability because the transmitter is vulnerable to water damage). Each set is provided with 2 magnetrons of different dimensions (for different resonant frequency ranges) to provide frequency diversity (1 is for WARM modes only). Each magnetron has 2 basic frequencies, so the radar as a whole will operate at base frequency, base plus 200, plus 800, and plus 1000 MHz. The set can be fine tuned within up to 5 MHz around any of the base frequencies. Such tuning is usually manual but can be automatic. In the event of jamming, the set can continue to transmit on 1 magnetron (with the appropriate receiver shut down) while using the other. In theory, a spot jammer will be locked onto the first signal and will miss the second. Special permission is required to shift to the war reserve frequencies of the 2 magnetrons.

There are 2 modes, search and track, with a separate operator for each. As in Square Tie, targets are designated to FCS computer track by means of a joystick, which maneuvers a pair of angle marks (a fork) and a range strobe on the face of the PPI. The computer measures angle rates; the operator merely keeps the tracking beam on the target. A key literally switches the waveguide leading from the transmitter from mode to mode. In search mode, the radar scans vertically while it rotates. The waveguide leads into a spinner rotating at 40 rpm, feeding a series of horns in sequence. The horns in turn radiate signals that, when they are focused, emerge at a series of elevations of 0–40 deg. When the radar is switched to track mode, the nacelle stops training. A separate mechanism scans the beam in a cross-shaped pattern around the target position derived from the tracking mode, ± 3 deg in elevation and ± 5 deg in train. It seems likely that the radar can auto-track in this mode because the beam excursions around the target position should provide it with error signals. At low elevations (less than 5 deg) the lower part of the vertical scan is cut off to reduce sea clutter. The radar can switch from feed to feed by means of a tilting plate analogous to the mirror in a single-lens reflex camera; the cross-shaped tracking feed is in the center of the tilting plate. The tilting plate is covered by lines of conductors at a 45-deg angle to the vertical; the nacelle cover has similar vertical lines of conductors.

As in Square Tie, the radar performs rate-aided tracking. The limitations of the computer make it very difficult to track fast crossing targets; Captain de Sam Lazaro recalled that a Soviet instructor considered this limitation immaterial because the system was intended mainly for point defense, in which case angular rates would not be very large.

The Indian government laboratory (DRDL) developed a replacement for MR 104, using the same antenna but a new transmitter for better ECCM and a new solid-state computer for better search and tracking (maximum closing rate increased to 900 kt). Work was completed in the early 1980s, and this new radar will presumably be retrofitted on board Indian Osas, Nanuchkas, and Kashins. In contrast to earlier Indian-developed modifications to Soviet equipment, this one was not reported to the Soviets.

◆ Bass Tilt (MR 105)

Muff Cob is similar in concept to Drum Tilt but is somewhat less sophisticated, slower, and less efficient; its stabilizer is older and less reliable. The associated coaxial television camera is used only for visual target identification (which is necessary in firing at towed targets) and apparently not as a backup in case of jamming. As in MR 104, there are 4 preset frequencies, but in this case there is only a single tunable magnetron. Tuning to the second frequency is by solenoid, but tuning to the third and fourth frequencies is manual and is limited to a range of 100 MHz. The maximum range is about 24 nm. Like MR 104, MR 105 scans 0–40 deg in elevation. The associated computer carries ballistics for 30-mm, 57-mm, and 76.2-mm guns.

SHIPBOARD ECM

Captain de Sam Lazaro reported Soviet insistence on virtual EMCON. The radars described above, for example, are designed to transmit briefly and then to project target position ahead, transmitting only intermittently. Similarly, he described very disciplined communications policy. Any commander making an unauthorized transmission must submit a special report, which may cause him considerable trouble. Yet the Soviets have failed to realize their ideals, and the U.S. Navy can rely on passive targeting. Captain de Sam Lazaro reported that the Indian navy adopted Soviet communications practices and used them successfully during the 1971 war with Pakistan. For example, the ships of the task force attacking Karachi closed each other to communicate by wire telephone and loud hailer; detailed instructions were passed in writing by high wire.

One observed consequence of the very limited transmission

policy was that ships could not tell when their radios had drifted off the assigned frequencies. Captain de Sam Lazaro reported that in small-attack-boat units about half the radios typically wandered off frequency, so communication was nearly impossible. A policy review was planned, but as of 1984 it had not been carried out.

As of the late 1970s, it was Soviet practice to designate a single ship of a squadron as radio communications ship. Communications within the group were, as far as possible, either visual or line-of-sight radio. Similarly, when ships operated in formation, radar transmissions were minimized by designating one ship as short-range guard ship and another as air-warning radar guard ship (it is not clear how, if at all, ships transmitted radar data without extensive data linking). Surface-search radars operated in single-sweep mode to avoid interception. During peacetime all radars of a given type operate at a fixed frequency to avoid disclosing war reserve operating modes (WARMS). Captain de Sam Lazaro recalled that the use of spot jammers was generally discouraged but that broad-band noise jamming was frequently exercised.

The typical ESM equipment on board an Osa-class missile boat is as follows:

- VHF search receiver (100–300 MHz); some sets can be set to ignore up to 50 channels used for friendly signals. The antennas are an omnidirectional monopole passing through a horizontal loop (a ski pole) and a dipole typically at the end of a yardarm. The antennas have considerable blind zones, so an operator switches from antenna to antenna to maintain continuous reception. The combination of very high self noise and external noise limits the effective range of sets on board Osas to 12–15 nm. The bearing accuracy is about 5 deg (using a PPI). The set also has a digital frequency display and a panoramic (A-scan) display. This receiver can also function as a main communications receiver (ship-to-ship or ship-to-air).
- X–C-Band Search Receiver for missile targeting, probably based on technology acquired from Signaal. During the 1970s at least the Black Sea Fleet considered retrofitting newer Osa-IIs and Nanuchkas with this device. These receivers were supplied to such foreign customers as India, Iraq, Somalia, Vietnam, and Yemen. On board Indian Nanuchkas, its nearly cylindrical antenna (containing a directional spinner) shares the big Band Stand radome with a Square Tie surface-search radar; it occupies the after side of the mast on board an Osa-II. The receiver is set for either X- or C-band signals. Its displays are a digital frequency readout, a B-scope (signal strength and, presumably, PRF), and a PPI for bearing (correct to 2 deg at night, slightly more by day).

Typically, a squadron of Osas would use a single watch frequency, such as 136.5 MHz, for DF reporting and triangulation.

In the early 1970s the Soviets reportedly adopted a standard jammer in Nanuchkas and in Kashin-class destroyers (and then in earlier ships in 1974–78). It was capable of both broad-band noise jamming (at about 900–1300 MHz over a 20–40-MHz band) and range-gate stealing, using small, rotating, horn-shaped antennas mounted on the yardarms. A later version uses a fixed reflector with what amounts to a rotating feed. The receivers (not the jammers) use TWT amplifiers.

Current (1988 and later) Indian ships with Soviet equipment have jammers that can lock on to the target signal and can conduct continuous ESM search for radars. A single-loop/whip DF system on board a submarine (presumably a Kilo) was credited with the ability to pick up and analyze a radar after a single azimuth sweep lasting only about 3 sec. Radars are now fitted with circuits that automatically warn the operator that an enemy jammer is active. It is not clear whether these are local improvements or Soviet-supplied modifications.

Captain de Sam Lazaro reported that the Soviets use both chaff rockets and chaff balloons. The Nanuchkas are the smallest units with chaff rockets (12 rockets/launcher). The launch-

ers cannot be trained, but they can be elevated by manual control, the range being set directly by reference to a graduated quadrant. Each rocket has a manually set time fuze, and it is fired by electric squib. The navigating officer uses a nomogram table to determine the firing range, which, in the smaller ships, is passed orally to the chaff operator at the launcher. Quite elaborate firing doctrine has been developed for formations, only

very simple messages being required to open chaff fire. Captain de Sam Lazaro reported that, depending on conditions, chaff clouds could persist for 6-45 min.

It appears that the Soviets first became interested in shipboard chaff with the advent of U.S. radar-guided antiship missiles, which the Soviets thought could overcome their active countermeasures.

ABOUT THE AUTHOR

Norman Friedman is recognized worldwide as a leading naval writer and defense analyst who specializes in technical and strategic issues. His work shows both an understanding of current technology and profound appreciation of history and its application to the present. As a consultant to various U.S. governmental agencies and defense contractors, he has examined the technology of national mobilization, Soviet responses to U.S. naval innovation, the utility of ballistic-missile defense, and strategic conflict with the Soviet Union, among other subjects.

Praised for his ability to explain complex technology to the layman, Friedman has written many successful books on naval ships and weapons that combine technical analyses with an examination of the historical, political, and economic influences on design and development.

His popular illustrated design histories published by the Naval Institute Press include *U.S. Destroyers*, *U.S. Aircraft Carriers*, *U.S. Cruisers*, *U.S. Battleships*, and *U.S. Small Combatants*. Among his other books are *U.S. Naval Weapons*, *Naval Radar*, *The Postwar Naval Revolution*, and *Submarine Design and Development*.

Friedman writes articles on a wide range of defense subjects that appear regularly in journals throughout the world. He also contributes a monthly column on world naval developments for the Naval Institute's *Proceedings* magazine.

The Naval Institute Press is the book-publishing arm of the U.S. Naval Institute, a private, nonprofit professional society for members of the sea services and civilians who share an interest in naval and maritime affairs. Established in 1873 at the U.S. Naval Academy in Annapolis, Maryland, where its offices remain today, the Naval Institute has more than 100,000 members worldwide.

Members of the Naval Institute receive the influential monthly magazine *Proceedings* and discounts on fine nautical prints, ship and aircraft photos, and subscriptions to the quarterly *Naval History* magazine. They also have access to the transcripts of the Institute's Oral History Program and get discounted admission to any of the Institute-sponsored seminars regularly offered around the country.

The Naval Institute's book-publishing program, begun in 1898 with basic guides to naval practices, has broadened its scope in recent years to include books of more general interest. Now the Naval Institute Press publishes more than forty new titles each year, ranging from how-to books on boating and navigation to battle histories, biographies, ship and aircraft guides, and novels. Institute members receive discounts on the Press's more than 375 books.

Full-time students are eligible for special half-price membership rates. Life memberships are also available.

Norman Friedman is an internationally respected defense analyst specializing in strategic and technical issues. A longtime consultant to U.S. government agencies and former deputy director of national security studies at the Hudson Institute, he is known for his ability to explain complex technology to the layperson.

Dr. Friedman, who holds a Ph.D. in physics from Columbia University, has written many successful books on navy ships and weapons that combine technical analyses with discussions of the historical, political, and economic influences on design and development. Among his seventeen books are five illustrated design histories of American warships; studies of naval radar, U.S. naval weapons, and British carrier aviation; and the first in-depth analysis of the war against Iraq.

Dr. Friedman also writes articles on a variety of defense subjects for journals published worldwide and contributes a monthly column on world naval developments to the Naval Institute's *Proceedings* magazine.

Books by Norman Friedman available from the Naval Institute Press:

British Carrier Aviation: The Evolution of the Ships and Their Aircraft

352 pages, 400 illustrations. ISBN 0-87021-054-8

Desert Victory: The War for Kuwait

440 pages, 80 illustrations. Hardcover: ISBN 1-55750-254-4; Paperback: ISBN 1-55750-255-2

Submarine Design and Development

192 pages, 190 illustrations. ISBN 0-87021-954-5

U.S. Aircraft Carriers: An Illustrated Design History

427 pages, 321 illustrations. ISBN 0-87021-739-9

U.S. Battleships: An Illustrated Design History

463 pages, 330 illustrations. ISBN 0-87021-715-2

U.S. Cruisers: An Illustrated Design History

488 pages, 309 illustrations. ISBN 0-87021-718-6

U.S. Destroyers: An Illustrated Design History

489 pages, 309 illustrations. ISBN 0-87021-733-X

U.S. Small Combatants: An Illustrated Design History Including PT-Boats, Subchasers, and the Brown-Water Navy

500 pages, 275 illustrations. ISBN 0-87021-713-5

U.S. Naval Weapons

287 pages, 322 illustrations. ISBN 0-87021-735-6

All the World's Naval Arsenals at Your Fingertips in a Single Volume

No Other Unclassified Resource Provides—in One or Even Several Volumes—the Comprehensiveness of This New Updated Edition.

The Naval Institute Guide to World Naval Weapons Systems 1991/92

- Expanded! Nearly double the size of the 1989/90 edition, with full descriptions of systems not previously covered.
- Fact filled! Includes over 900 pages of essential data on naval guns, missiles, radars, mines, sonars, torpedoes, command and control equipment, and countermeasures, along with thorough coverage of the computers that control them.
- Comprehensive! Describes every shipboard and naval-related airborne system in service and under development, including those used in the Persian Gulf.
- Heavily illustrated! Includes more than 1,300 photos and line drawings, many never before published, 80 percent more than the previous edition.
- Informative! Analyzes each system and explains how various systems fit together tactically.
- Easy-to-use! Information is logically organized by warfare area and systems type and thoroughly indexed.
- Timely! Assesses the performance of weapons systems in Operation Desert Storm, the new strategic and tactical challenges facing NATO naval forces, and the effects of Soviet political and economic events on its naval arsenal—with late-breaking information appearing in an addendum.
