The surveillance system consists of 2 paraboloids arranged back to back for a high data rate. They differ in configuration (particularly at their edges), and each appears to be made in 2 layers. In other cases, this type of construction is used with 2 beams of different polarization, 1 layer reflecting only in 1 polarization. Such an arrangement might provide 2 beams at slightly different angles, so the radar could not only acquire a target but also determine its position more precisely (similarly, the 2-beam radar might provide initial altitude information). The high data rate (compared to the 1-antenna Pop Group) may have been chosen in response to a new requirement to protect ships against very small antiship missiles appearing suddenly at the horizon at a relatively short range. The double surveillance radar incorporates its own IFF interrogators, carried above the search antennas.

Cross Sword has 2 smaller antennas above its main antenna, aligned with its main axis. One is probably a missile-command

Cross Sword missile director (for SA-N-9 missiles) on board the *Udaloy*-class destroyer *Admiral Vinogradov*, July 1990. Note the IFF interrogators mounted on the search radar, and what appears to be a fixed telescope on the left-hand side of the director. (S. Zaloga)

transmitter. The other might well be a phased-array missile-beacon tracker. There are also electro-optical devices at the lower corners of the main antenna.

In the case of Cross Sword/SA-N-9, the initial installation was on board *Udaloy*-class destroyers, which have 8 vertical launchers but 1 or 2 directors. Since the missiles are all vertically launched, either director should be able to control all of them. An analogy can be made with the design of the *Kirov*, in which all the missiles are forward but there is a second director aft. Past Soviet practice has been to associate 2 launchers or launcher arms with each target channel, so one would assume that Cross Sword can handle 4 targets with a total of 8 missiles. The presence of 2 directors on the same ship would not be too significant since each has only a limited effective arc (whereas each missile, like a Western vertically launched weapon, can presumably cover all 360 deg).

◆ Drum Tilt

This radar operates in C- and X-bands; on Osa missile boats and others Drum Tilt controls twin 30-mm guns. Drum Tilt was the first of a new generation of drum-shaped fire-control antennas (1961). The housing is tipped up permanently at an angle of about 25 deg, and approximate dimensions are 1.5 m in diameter and 1.7 m in length. This radar is fully stabilized. Like the earlier Hawk Screech, it is almost certainly designed for TWS operation, the feed rather than the antenna as a whole scanning a limited volume of space. The fixed radome elevation would seem to imply that the antenna itself is fixed in elevation. TWS operation presumably suits Drum Tilt to more conventional search operation (it is the primary search radar in *Natya*- and *Yurka*-class minesweepers). Reported acquisition range on an aerial target is 41,000 m [about 45,000 yd], and maximum tracking range is 22,800 m [about 25,000 yd]. Reportedly, at least the early radars of this type required skilled operators because the radar tended to lose targets even if locked on. The initial version could track only a single target. The Soviet designation is Rys.

Drum Tilt radar on board an East German *Koni*-class frigate. (U.S. Naval Institute)

◆ Eye Bowl

S-band tracker for the SS-N-14 ASW missile, which is command-guided. Ships with Head Lights SAM guidance radars use those sets to track and guide their SS-N-14s. Eye Bowl (2 antennas) is on board *Kirov*-class cruisers, *Udaloy*-class destroyers, and *Krivak*-class frigates.

Eye Bowl (SS-N-14) control antennas are shown above the bridge of the Krivak-class frigate *Komsomolets Litvii* at Kiel, June 1990. Below them is a Pop Group director (with a Don Kay antenna below it); above them are Palm Frond and Head Net C, with a Salt Pot IFF interrogator above the Head Net radar. (L. van Ginderen)

Eye Bowl on board the *Udaloy*-class missile destroyer *Admiral Vinogradov*, 1990. (S. Zaloga)

◆ Front Dome

A Front Dome missile-guidance radar, on board the destroyer *Otlichnyy*, at Norfolk, 1989. The optronic device next to the guidance radar is unique to the *Sovremennyy* class and is paired near the SA-N-7 launchers; presumably, it is an electro-optical part of the SA-N-7 system. (S. Zaloga)

The missile guidance for SA-N-7 is a C-band tracker-illuminator. It resembles the Bass Tilt gunfire-control radar but is larger. In the *Sovremennyy* class, 3 such radars are associated with each SA-N-7 launcher.

◆ Front Door

Tracker/command antenna for SS-N-3 and -12 antiship missiles. It is a slightly cylindrical antenna, taller than it is wide, which can scan in bearing. Echo- and Juliett-class submarines have a second antenna, Front Piece, which probably tracked the missile in altitude. It folds up atop the main antenna. The submarine version of the antenna folds down about its horizontal centerline. Its housing turns 180 deg to expose the antennas, and it can train to follow the outgoing missile. Surface-ship versions were initially designated Trap Door; they do not fold (but the version in the *Kiev* class folds down at one end, hence the name). The submarine antenna is now designated Front Door A, and Trap Door is now designated Front Door C. As an indication of size, the antenna in the *Kiev* is covered by a 3 × 5-m door.

Scoop Pair is the corresponding antenna on Kynda- and Kresta-I-class cruisers.

◆ Hawk Screech

Band: X (9.2–9.5 GHz) **Beam:** 0.6 deg
Peak Power: 150 kW **Pulse Width:** 0.6 microsec
PRF: approx 1250 pps
Scan Rate: 30–31 cycles/sec linear scan (narrow sector)
Antenna Dimensions: diameter approx 1.7 m

Hawk Screech radar on board an East German Koni-class frigate. (U.S. Naval Institute)

Hawk Screech is the X-band fire control for 45-mm, 57-mm, and 76.2-mm dual-purpose guns (1954); it always has an optical backup. Probably the radar conceived in 1949 and designated *Yakor'* by the Soviets, Hawk Screech introduced a new auto-track technique (lobing) that was used in several other radars. This radar was fully stabilized, for blind-fire and autotracking. Maximum range is probably about 6500 yd and 18,000 ft (altitude). The new tracking technique was almost certainly TWS, the technique used in several contemporary or somewhat later missile-control systems. The scanning beam is generated by a rotating feed (evidenced by its circular housing) in an "organ-pipe." The radar presumably nods in elevation to acquire its target. Although all Western TWS FCSs have been limited to relatively slow-moving surface targets, in the early 1950s the Soviets seem to have become interested in TWS approaches to dealing with very fast targets. Presumably, the radar operator tracks a target and then uses a succession of plots to insert data that the radar can project ahead, for rate-aided tracking. If that is indeed the case, then these systems are unlikely to be very

effective against maneuvering targets. That in turn would explain the rise of a new generation of systems, such as Kite Screech and Muff Cob.

◆ Head Lights

The X-, C-, and S-band missile-control radar for SA-N-3 consists of 2 large (4-m) and 2 small (1.8-m) tracking dishes and a small dish for the command uplink. The large dishes track the target, the small dishes the missile. Soviet doctrine appears to be to fire 2 missiles (from 1 launcher) at the target, and in this system each missile apparently needs its own target tracker, the command signals presumably being generated by measurement of the expected miss distance between missile and target. There are several versions. Head Lights B added SS-N-14 control. All *Kievs* have Head Lights C, which presumably has additional power to control a longer-range version of SA-N-3. Head Lights C appeared in the Kara class. The early *Kresta-II*s had Head Lights B forward and Head Lights A aft, but later ones had Head Lights B fore and aft.

Head Lights was probably 1 of the earliest Soviet applications of monopulse radar technology.

The Soviet name is Grom (Thunder).

Head Lights on board the cruiser *Kerch*, 1989. (Eric Grove)

◆ Kite Screech

Kite Screech B radar director for 130-mm guns, on board the destroyer *Otlichnyy* at Norfolk, 1989. The hole is for a television camera. The radar abaft the director is Palm Frond. (S. Zaloga)

The fire control for 100-mm and new 130-mm dual-purpose guns is similar in appearance to Hawk Screech but larger.

The fire-control radar for 100-mm guns and for the new 130-mm dual-purpose guns is externally similar to Hawk Screech but has a larger dish and almost certainly a very different principle of operation. These radars have a characteristic V-shaped strut supporting a feed, most likely monopulse. Kite Screech appeared about 1975. Kite Screech A (mid-1970s) operates at C- and Ka-bands. Kite Screech B (early 1980s) operates at X- and Ka-bands.

◆ Kolonka

Kolonka is a simple optical director, used to control light automatic guns, such as AK 230s, which lack any on-board controls. Kolonka carries a very simple sight with speed rings, so it is almost certainly not a lead-computing sight like the old U.S. Mk 14 used in the Mk 63 fire-control system.

A Kolonka visual sight on board a Soviet torpedo boat. This is not a lead-computing sight; the operator uses simple speed rings to estimate the required lead. The radar in the background is Drum Tilt. (TASS from SOVFOTO)

◆ Muff Cob

For 57-mm twin automatic guns, Muff Cob operates in C-band and has an attached TV camera. This system first appeared about 1962. Although Muff Cob has a barrel-shaped radome similar to that of Drum Tilt, it elevates; therefore, the entire antenna presumably tracks its target in both elevation and azimuth. Muff Cob might, therefore, be seen as marking the transition to monopulse tracking radars, even though the TWS radars have survived.

The Soviet name is Bars (Wildcat).

Muff Cob 57-mm gunfire-control radar director, on board the Indian frigate *Ganga*. In Indian service this director is designated MR-103. (Ships of the World)

◆ Owl Screech

This C- and X-band fire control for 76.2-mm DP guns (about 1961) is an improved Hawk Screech. The cylindrical (rotating) feed is tilted at 45 deg to the horizontal so that its beam scans in both elevation and azimuth. The reflector's diameter is about 2.3 m. Peak power is reportedly 250 kW. There is no associated backup director/target designator.

The Mod Kildin-class missile destroyer *Ozorlivyy* shows Owl Screech (above) and Hawk Screech (below). Owl Screech is the larger and has its feed at 45 deg to the horizontal. (Markku J. Paananen, 1979)

◆ Peel Group

This missile-control radar for SA-N-1 consists of a command dish plus 2 groups of antennas: 1 to track the target, the other to track the 2 missiles normally fired in a salvo. Each group consists of 2 parabolic reflectors, 1 vertical and 1 horizontal; hence the name (they resemble pieces of orange peel). The feeds are almost certainly organ-pipe scanners, rotating rapidly to form beams scanning in height and elevation, like the beams of the old U.S. SPS-8 and SPS-30 series. Presumably, the command dish sends the missiles signals for vertical and horizontal course correction. The target is tracked in S-band, the missile in X-band. The director also carries a TV camera for use under heavy jamming. Maximum range is about 30–40 nm.

Although unknown in contemporary Western missile-control systems, Peel Group's TWS operation was typical of contemporary Soviet missile-guidance radars. Compared to a single conscan tracker, a TWS tracker requires much less in the way of accurate radar-antenna movement, as the antenna need not track the target (except when the target reaches the edge of the available beam motion). TWS tracking is, however, relatively difficult to automate. In the Soviet case there are probably separate elevation and azimuth operators who match the observed target motion with rate-aided tracking, applying corrections as required. Such operation would seem to imply poor performance against a radically maneuvering target and explains the shift to

Peel Group missile (SA-N-1) fire-control radar directors on board the Kashin-class destroyer *Strogii* at Massawa, 1972, showing the characteristic pairs of large and small horizontal and vertical antennas, for target and missile tracking. (Royal Navy)

Peel Group on board a Kanin-class missile destroyer. (U.S. Navy)

monopulse operation (i.e., to fully automatic tracking) in the next-generation Head Lights (SA-N-3) and Pop Group (SA-N-4). TWS fire control also carries the disadvantage that the radar spreads most of its energy outside the target and, thus, should be easier to jam (and should enjoy shorter effective range) than a radar continuously pointed at a target.

The major contemporary Western naval example of TWS operation was the World War II Mk 8/Mk 13 main-battery fire-control radar. In its case, TWS permitted the same radar to observe both the target and the nearby splashes. The alternative lobing radar could track a target more precisely, but it could not observe splashes to either side. In theory, a single pair of TWS antennas could track both target and missiles (as in the land-based equivalent to Peel Group, Low Blow), but Soviet naval practice has been to provide separate missile and target trackers. In theory, at least in this case, that should permit the use of more energy-efficient missile trajectories (the missiles need not fly near the targets), as well as up-and-over surface-attack trajectories.

The Soviet name for this system is Yatagan.

◆ Pop Group

Pop Group is the missile-guidance radar for SA-N-4, incorporating its own acquisition radar, atop the cab, with target and missile trackers in front (flat plate antennas). Presumably the acquisition radar is colocated with the trackers to reduce hand-over delays; in this sense Pop Group is analogous to the Signaal M20 series and to the U.S. Mk 92.

Although the missile launcher has 2 arms, there are only a single missile-tracker antenna and a single target-tracker antenna. Dual operation would still be possible using polarization diversity, 2 signals sharing a common antenna. That sharing might be the reason for the flat plate some distance ahead of the antenna proper.

The analogous land system (Land Roll) has 1 large and 2 small antennas plus a surveillance/acquisition antenna similar in appearance to that of Pop Group. In the land system, the search antenna operates at 6–8 GHz (slightly below Western C-band wavelength), with stacked feeds (probably for frequency diversity, possibly for integral IFF). Reportedly, the big target tracker is a frequency-hopping monopulse antenna operating at 14.2–14.8 GHz (slightly above X-band as used in the West); re-

A Pop Group missile director on board the cruiser *Marshal Ustinov* at Norfolk, 1989. (S. Zaloga)

ported maximum range is 25 km (effective range 20 km). The target tracker is almost certainly an inverse Cassegrain. The smaller antenna is a higher-frequency replica of the larger.

In the case of the land-based system, the 2 missile trackers can operate at different frequencies, to track 2 separate missiles engaging the same target.

◆ Scoop Pair

This is the SS-N-3 guidance antenna on Kresta-I- and Kynda-class cruisers. One antenna group is used for each quartet of missiles; it consists of 2 separate stabilized antennas (top and bottom), each provided with a pair of horns and what appear to be 2 superimposed reflectors, about 4.2 m wide. With dual polarization, each antenna set could handle 2 sets of signals, to control 2 missiles. The system dates from the early 1960s, when the Soviets were using TWS systems to control surface-to-air missiles. Presumably, Scoop Pair is an application of much the same technology.

◆ Sun Visor

Band: X (9.3–9.44 GHz) **Beam:** 0.8 deg
Pulse Width: 0.2 microsec **PRF:** 2500, 3500 pps
Scan Rate: 40 scans/sec

This X-band fire control for 100-mm and 130-mm dual-purpose guns is mounted on a Round Top or Wasp Head director. Sun Visor appeared in 1953. The antenna feed is a dipole, and elevation limits are +90/–5 deg. Variations in the feed differentiate between Sun Visor A and B.

Sun Visor radar is visible on the front of the Wasp Head director of this Chinese Riga-class frigate. The main air-search radar above is Slim Net. The dome alongside the mast is presumably 1 of the 2 elements of Jug Pair, which is probably a Chinese version of Watch Dog (ESM). (U.S. Naval Institute)

◆ Top Dome

The X-band missile-guidance radar for SA-N-6 uses a 4-m-diameter radome fixed in elevation but trainable. Three smaller radomes are mounted on the face of the mounting pedestal, and there is also a much smaller hemispheric radome below. The smaller radome may be the link transceiver for the track-via-missile system. The main tracking radar almost certainly operates in X-band, in analogy to the land-based Flap Lid engagement radar.

Each Top Dome is associated with 6 vertical launchers; on the basis of 2 missiles per target, presumably Top Dome can simultaneously control 3 intercepts against 3 targets. Since

The secondary battery director of the Sverdlov-class cruiser *Dzerzhinskiy*, now discarded, shows its Sun Visor radar and its range-finder. The aerials in the background were part of the Fan Song radar controlling the SA-N-2 missile carried by this ship. In the foreground are standard twin 37-mm guns. (TASS via SOVFOTO)

there is no separate target or missile tracker, the system must time-share between the target- and missile-tracking functions. Because Top Dome does not elevate, it must scan electronically (as, indeed, the land-based SA-10 fire-control radar does).

In the past, it has been Soviet practice to assign 1 launcher per director per target. However, it is possible that the Soviets consider the array of 6 SA-N-6 launchers as a single entity, and that doctrine now calls for more than 2 missiles per engagement.

Top Dome missile-guidance radar on board the Soviet *Slava*-class missile cruiser *Marshal Ustinov* at Norfolk, 1989. (D. Steigman and S. Zaloga)

Top Dome missile-guidance radar on board the Soviet *Slava*-class missile cruiser *Marshal Ustinov* at Norfolk, 1989. (D. Steigman and S. Zaloga)

◆ IFF

As in the Western navies, the Soviets have developed interrogator-transponder IFF systems. There is no evidence of any attempt to integrate IFF for a ship; each air-search radar has its own interrogator. Transponder feeds are integrated into the feeds of most of the standard microwave radars, but it appears that the big frequency-scanning types require separate interrogators. Sky Watch has small flat panels near its main panels; they are presumably interrogators. The other large-radar interrogators are Long Head (a long array of dipoles, e.g., atop Top Plate) and Tooth Brush (square enclosure atop Top Sail and Top Steer and their relatives). Small combatants generally have Square Head (a 2.0×1.5 -m reflector carrying an array of vertical dipoles). Square Head dipole dimensions correspond to a wavelength of 50 cm (600 MHz). In an Osa-class missile boat there are 2 Square Heads, 1 for the Square Tie surface-search radar and 1 for the Drum Tilt gunfire-control radar. It is not clear whether different interrogators correspond to different IFF systems. Square Head(s) and a High Pole A or B transponder are part of a Soviet system designated Nkhrom-2. The other current transponder is Salt Pot (there are A and B versions), generally in larger ships. A few older large ships (*Moskva*- and *Kynda*-class cruisers) have an earlier transponder, Hour Glass. Presumably, it is part of an older IFF system now being discontinued (some ships have both it and Salt Pot).

OPTRONICS

◆ Squeeze Box

In *Sovremennyy*-class destroyers and in amphibious ships with 140-mm bombardment rockets, Squeeze Box probably combines infrared television with a laser range-finder. An "uncovered" version is carried by Pomornik-class ACVs. Squeeze Box is a fire-control device, not a remote-vision device like Tee Plinth or Tin Man.

◆ Tee Plinth

This television sensor was installed in the 1960s and 1970s and is now replaced in newer ships by Tin Man. Tee Plinth supplements the large optical periscopes that modern Soviet warships (from the *Kynda* class on) carry either atop or abeam their bridges. Both Tee Plinth and these periscopes presumably serve a below-decks command center. Such a center would be re-

Squeeze Box on board a *Sovremennyy*-class destroyer. This electro-optical device is associated with 130-mm-gun fire control; it contains a laser, presumably for range-finding. Reports that the same device was used to blind or dazzle pilots temporarily (like the British LDS) suggest that it can operate continuously, which in turn would be useful primarily to guide shells. (S. Zaloga)

quired if, as is said to be the case, the Soviets plan to fight their ships under fallout and chemical-attack conditions, using citadel protection (the center would be within the below-decks citadel). This type of arrangement would correspond to the much earlier and nearly universal practice, in the world's cruisers and battleships, of providing command facilities under armor, in a conning tower, served by periscopes projecting through the top of the tower. Presumably, Tee Plinth replaces human lookouts, who could not survive in a nuclear- or chemical-warfare environment.

The presumed existence of a below-decks command center is suggested by the very minimal dimensions of the bridges of ships of the *Kynda*, *Kashin*, *Kresta*, *Kara*, and *Moskva* classes. Most are just not large enough to include adjacent missile and radar control spaces. These spaces must, therefore, generally be below the bridge, and they are probably the same spaces served by the periscopes. One would suspect, then, that the Soviets tend to combine the functions of a Western CIC and a Western ship-control space, using television and periscopes to provide the commanding officer, who is below decks during combat, with a reasonably complete picture of the outside world. The U.S. Navy will probably adopt a somewhat similar arrangement

The bridge structure of the cruiser *Kerch*, 1989, showing the forward Head Lights director (which controls the SS-N-14 ASW missiles as well as the SA-N-3 battery) and an Owl Screech radar gun director further aft, above the enclosed bridge wing. The object visible above the Owl Screech is a periscope. The object just beneath the Head Lights radar is a Tee Plinth television camera. (Eric Grove)

The periscope in the enclosed combat command station of the cruiser *Kerch*, on the same level as, and abaft, her bridge. This station does not contain radar fire-control equipment but does include radar directors like the one visible in the background, as well as a steering console. (Eric Grove)

in its next-generation ships, to reduce the sheer size of its bridges and also to make collective protection (i.e., a citadel system) more practicable. For the U.S. Navy, a smaller bridge is attractive because it would reduce the ship's radar cross section. The Soviets presumably had to reduce bridge dimensions to provide more topside space for their large radars and weapons directors; the *Kynda* and later classes are very cluttered topside.

Ironically, it appears that the Soviets had to adopt larger topside bridges, presumably for better ship-handling, in later designs, such as the *Krivak*, *Kiev*, and *Kirov*. This development would seem to parallel U.S. experience with conning towers (i.e., protected command centers) in battleships before World War I. About 1910 the U.S. Navy sought to minimize open bridge space so that commanders would always operate from their protected conning towers. During World War I, when U.S. battleships operated with the British Grand Fleet, the American commanders found it difficult to conduct high-speed maneuvers from closed conning towers; substantial (unprotected) bridges were restored, though not on the same scale adopted by other navies. All major Soviet ships are still provided with the periscopes and electro-optical sensors (televisions) characteristic of their below-decks command spaces, i.e., of their citadel protection.

Tee Plinth and its successor (Tin Man) are trainable. The Soviets also use small fixed television cameras (Tilt Pot).

◆ Tin Man

Successor to Tee Plinth, Tin Man probably incorporates a laser range-finder, in newer ships.

FIRE-CONTROL SYSTEMS

Later radar fire-control systems (e.g., Hawk Screech) are designated by the associated radar. The systems listed here are early postwar optical/radar directors.

◆ Wasp Head (Sphaera 50)

This dual-purpose director is installed in Riga-class frigates. The associated radar is Sun Visor. The director is stabilized and is suited to blind-fire. Maximum tracking range is 81,000 yd, and maximum antiaircraft speed is reportedly 950 kt (70 kt for surface targets). This system is not capable of autotracking.

A Tin Man optronic device on board the cruiser *Kirov*. The nearby radome is a Big Ball for satellite communications. (Sea Power)

UNITED KINGDOM

RADARS

◆ Type 262

Band: X Beam: 5 deg Peak Power: 30 kW
Pulse Width: (i) 20 (ii) 200 microsec PRF: 1500 pps

This close-range armament blind-fire (CRBF) radar survives in the GWS 21 Sea Cat missile system (Indonesian "Tribal" class). Type 262 oscillates in both planes while searching for a target and then tracks by conical scanning, the antenna spinning. The associated fire-control system tracks by measuring apparent target angular rate (using a gyro).

Type 262 could autotrack at 5000 yd, acquiring its target at 7000 yd. Targets were acquired by scanning 30 deg/sec in azimuth (elevating 3 deg at the end of each horizontal sweep), at the same time searching for 750 yd on either side of the indicated range at 30 cycles/sec.

◆ Type 275

Band: S Beam: 6 × 8.2 deg Peak Power: 400 kW
Pulse Width: 0.25, 0.5, 0.75 microsec PRF: 500 pps
Antenna Dimensions: diameter 4 ft (2 dishes)

This dual-purpose fire-control radar was introduced at the end of World War II and is still in service in India and in Bangladesh.

HMS *Puma*, a Type 41 anti-aircraft frigate, shows her Mk 6 director with its Type 275 fire-control radar (just abaft her bridge). The gun mount forward is a 4.5-in Mk 6. Two sisters survive in the Bangladesh Navy. (HMS *Excellent*)

Type 275 was intended for the postwar Mk 6 director, and some were also fitted to U.S.-supplied Mk 37s. The antennas are 4-ft dishes that can elevate and that scan conically. Detection range is 36,000 yd (tracking range 30,000 yd).

◆ Type 277/278

Band: S **Beam:** 4.5×2.2 deg **Peak Power:** 500 kW
Pulse Width: (i) 0.7 (ii) 1.5 or 1.9 microsec
PRF: (ii) 500 pps **Scan Rate:** 7.5 rpm
Antenna Dimensions: 8-ft spherical parabola with clipped sides

Type 278 radar, on board a "County"-class missile destroyer (second series). (R. Cheung)

Data are for the postwar 277Q, with antenna outfit ANU.

This nodding height-finder is still in service on board "County"-class missile destroyers and 1 Bangladeshi frigate. In modernized form (operating under weapons-system-computer control) this system was designated Type 278. Type 277Q performance: aircraft between 5000 and 20,000 ft could be detected at 55 nm, and height-finding range on an airplane at 20,000 ft was 60 nm.

◆ Type 293/993/994

Band: S **Beam:** 2×35 deg **Peak Power:** 500 kW
Pulse Width: (i) 0.7 (ii) 1.5 or 1.9 microsec
PRF: (ii) 500 pps **Scan Rate:** 5, 10, or 15 rpm
Antenna Dimensions: 12 ft

Data are for the 293Q version (antenna outfit ANS).

This short-range air/surface-search radar (target indicator in large ships) was succeeded by Type 993. The remaining examples are on board the Indian *Leopard*-class frigates. Estimated range was 30–35 nm.

Type 993 is Type 293 with a new "quarter cheese" antenna, outfit AKD. In this antenna the feed horn does not obscure the main radar beam, so that the beam is better defined, even over a broad tuning band. This antenna scans at 24 rpm.

Type 994 radar on board the British frigate *Penelope*, 1988. The slotted waveguide is for Type 1006. (A. Raven)

Type 994 retains the same antenna but has a new transceiver based on that of the Plessey AWS-4 private-venture radar. Installation, e.g., on board frigates, began in 1978. As of 1990, the AKD antennas of Type 994 are being replaced by AWS-4 antennas.

◆ Type 901

Band: X (9–10 GHz) **Beam:** 0.9 deg **Peak Power:** 750 kW
Pulse Width: 0.2 or 0.3 microsec **PRF:** 1840 pps
Gain: 24 dB **Antenna Diameter:** 9 ft
Scan: Conical, 2 deg at 30 scans/sec

Data above are illustrative; they apply to the earliest version of Type 901. In this version maximum range was 60,000 yd.

Type 901 radar. The gathering horn is on the other side. (R. Cheung)

The associated gathering beam was 7.4 deg wide, scanning over a cone 18.8 deg wide, at a peak power of 250 kW (0.1-microsec pulses).

The missile-guidance radar for the Sea Slug system survives in the Chilean navy. It was conceived in 1944 as the basis of a new long-range anti-aircraft system, then adapted to missile guidance. The antenna is stabilized in roll and pitch. It scans conically or in a rosette pattern, and it also generates a secondary (transmitted only) missile-guidance beam. The associated computer coordinates the beams. A third (gathering) beam is generated by a small horn on the right-hand side of the nacelle (the gathering radar was originally designated Type 902).

The front of the nacelle is a dielectric lens. A pivoted reflector inside (the beam-deflector unit) is fed by an off-center horn that can itself rotate about an axis perpendicular to that of the radar. A second horn is used to generate the guidance beam. The combination of reflector and horn motion produces a conical or rosette scan (a petal scan in British parlance), depending on whether the reflector rotates about 1 or 2 axes. Pulse coding is used to guide 2 missiles along the same beam (the radar tracks the missiles by transponder). Given different ratios of horn and reflector motion, it can also scan vertically or horizontally to acquire a target.

◆ Type 903/904

Band: X (8.5–9.05 or 9.05–9.6 GHz) **Beam:** 2 deg
PRF: 3000 pps **Pulse Width:** 0.1 microsec

This X-band conscan fire-control radar, used in the MRS 3 system, was based on the U.S. Mk 35 (which is described below). Data given here apply to the Mod 1 version, as used in MRS 3. Scanning was spiral (to acquire targets) or conical (for tracking). Minimum range was 32.8 yd, and maximum lock-on range was 29,500 yd. Range accuracy was 10 yd, and targets could be resolved within $1\frac{1}{2}$ deg or 25 yd. Typical preset range rates in the MRS 3 system were 180 yd/sec (closing) in anti-aircraft mode, or 22 yd/sec in the surface-fire mode. The director could turn 100 deg/sec when being run in to a designated target.

Type 903's development began about 1946, and the radar entered service in 1958. Type 904 is a modified version for Sea Cat missile control, as part of the GWS 22 system.

Users: Chile ("County" class and *Leander* class), India (*Leander* class), Indonesia ("Tribal" class), New Zealand (*Leander* class), Pakistan ("County" and *Leander* classes), and the United Kingdom (*Leander* class).

Type 904 radar-equipped GWS 22 Sea Cat missile director, with Sea Cat being fired. The open hood contrasts with the enclosed hood of the very similar MRS 3/903 combination. (U.S. Naval Institute)

◆ Type 909

Type 909 is the tracking and illuminating radar for the Sea Dart missile system. The typical installation includes 2 radars. Type 909 is normally radome-enclosed but may be seen uncovered when ships are undergoing alignment trials. It is relatively heavy and, reportedly, unreliable, and it is being replaced by a lighter-weight radar, derived from the Marconi 805SD. Some existing Type 909 radars are being replaced by a more reliable derivative, Type 909I.

Type 909 dish diameter is 2.4 m.

Type 909 with the radome removed. (R. Cheung)

A Type 909 radome, HMS Glasgow. The ship in the background is HMS Cumberland. (Author)

◆ Type 910

Type 910 is the X-band pulse-doppler target-tracking radar for the Sea Wolf point-defense missile system. Electronic angle tracking is used to make small angular corrections to boresight without moving the radar itself.

Type 910 tracks a 0.2-m² target at a range of about 10 km, and smaller targets at 5–6 km. The main dish is about 1.6 m in diameter (beamwidth about 1.5 deg). This radar also tracks

Type 910 Sea Wolf control radar on board HMS *Brazen*, 1984. (R. Cheung)

the Sea Wolf missile, using signals from transmitters in 2 of the missile's wings (the other 2 wings carry command-link receivers). Command signals are calculated on the basis of the difference between the missile's and the target's positions (differential tracking). Two 80-cm dishes alongside the main antenna carry the microwave command links for 2 missiles, which can, therefore, be fired in salvo against a single target. Multiplexing from a single dish was rejected as too complex. Command frequency is probably in the 10–15 GHz range. Between the main antenna and the 2 dishes is a gathering antenna consisting of a horn (for transmission) and 4 rectangular horns (for monopulse reception). The antenna also carries a television differential tracker, which uses a flare in the missile tail.

Marconi has developed a manually controlled infrared tracker that is being retrofitted into existing GWS 25 Mod 0 with the 910 tracker. The company is working on a fully automatic IR system for tracking and also for surveillance, to provide fully passive operation up to the point of launch, when the command link would have to be activated. Infrared alone is not sufficient, since it is not effective under some conditions, e.g., high humidity. Marconi therefore advocates a combination of 2 radar frequencies and infrared.

Type 910 is now being superseded by the lighter-weight Type 911. Two alternative replacements were considered. In Type 910M (about 1980), the television camera was replaced by a Blindfire Rapier DN181 mm-wave radar. There was also a Signaal VM40 radar director.

◆ Type 911 (805SW)

The lightweight Sea Wolf control radar, 1 of the Marconi 805 series, consists of 2 radars mounted side by side: A (left side of the array), a twist-Cassegrain narrow-beam reflector with a monopulse feed (and with an associated 4-horn monopulse cluster gathering antenna); and B (right side of the array), a tracker (offset folded Cassegrain reflector with a steerable sub-reflector). The receiver of Radar A is coherent-on-receive, measuring target velocity by FFT. The system measures the angle between the missile's and the target's paths. Both radars use filtered electronic angle tracking to overcome problems such as reflection from the sea surface.

Type 911 Sea Wolf control radar on board HMS *Cumberland*, 1990. (Author)

Radar A operates in X-band, radar B in Ku-band. Ku-band was chosen to overcome low-level multipath problems by frequency diversity. Both have magnetron transmitters. The director automatically selects the best of the 2 radars to track a given target. The drum-shaped command-link transmitter is located behind the Ku-band antenna, transmitting through it (commands are initially transmitted via the wide-angle beam cluster, then through antenna B after gathering). No electro-optical tracker (as in the original GWS 25) is fitted, as it would have required additional operators. Above-decks equipment weighs 1725 kg; between-decks equipment adds another 2155 kg. About 60 Type 911 radars had been sold as of late 1989.

Type 911 is a relatively elaborate device capable of controlling salvo-fired missiles. Marconi has developed a simpler, lighter XL version with a Javelin television on its right-hand side (to gather the missile), which is television or beam guided. The XL director has a large antenna that tracks the target, with 2 small (higher-frequency) dishes on its left-hand side (and a wide-beam horn between them, to gather the missile). The 2 dishes are the missile uplinks, operating in 2 frequencies to overcome multipath problems. The director weighs less than 700 kg and has a 1.2-m working circle (radius); the control console weighs 250 kg, and the transmitter/receiver cabinet another 700 kg. The tracker radar is the Marconi 1802SW.

The Marconi 805SW was adopted in preference to the Signaal VM40.

◆ Type 912

Type 912 is the British designation for the Italian Selenia Orion RTN-10X, used on board Type 21 (*Amazon*)-class frigates (with a Ferranti WSA-4 processor).

Type 912 radar director as installed on board a Type 21 frigate, with television camera visible at right. (GEC Sensors)

◆ Type 965/966

Band: P (about 1.4 m) **Beam:** 12×40 deg
Peak Power: 450 kW **Gain:** 20 dB
Pulse Width: (i) 3.8 (ii) 10 microsec **PRF:** (i) 400 (ii) 200 pps
Scan Rate: 8 or 10 rpm (depending on whether the power supply is 50 or 60 cycle)
Antenna Dimensions: 26 ft $\times$ 8 ft 11 in (or 16 ft 9 in) $\times$ 6 ft 1 in
Antenna Weight: 2425 or 5480 lb

Type 965 is the standard British long-range air-search radar of the 1960s, adopted in place of the roughly contemporary U.S. SPS-6. There are 2 alternative "bedstead" antennas (in effect, squintless horn arrays), AKE(1) and AKE(2), the latter in effect 2 AKE(1)s superimposed. Each of the 8 or 16 array elements is shaped as a reflector horn surrounding a loop dipole.

Reportedly, this radar performed poorly in the Falklands because, without MTI, it was unable to detect Argentine aircraft approaching from overland. A modified version with crude MTI, 965M, has been reported. Type 966, which may be a private designation, is Type 965 with a modernized transmitter/receiver (but with the same antenna), which Marconi advertised in the mid-1980s.

Type 965 was first proposed in 1953 (and revived in 1955) to meet a staff requirement for a small-ship air-warning radar. Marconi proposed a modification of the existing Air Ministry Type 15 Mk 5, with a redesigned aerial (16 $\times$ 4 ft, 1500 lb including the antenna-rotation motor) and a reduced radar office. The radar would scan at 6–10 rpm, with a 17-deg beam (190–215 MHz, 3.8-microsec pulses, gapless vertical cover, range 100+ nm on a 20-m² target). U.S. trials of 200 vs. 400 MHz radars (resulting in the adoption of the SPS-17 and then -28/29) were cited in support of this frequency choice; and the Dutch LW-02 was rejected because it would not meet the range requirement and because its high frequency would prevent detection of streamlined aircraft. In 1955 the aerial was expected to be 24 $\times$ 7 ft (beam 17 $\times$ 45 deg); LW-02 used a 19.5 $\times$ 9.75 ft antenna (2300 vs. 1800 lb, the latter figure including IFF). LW-02 would require a separate IFF antenna, special venting arrangements, and adaptation to British requirements (Anglicization).

Type 965 (AKE-2) on board a "County"-class missile destroyer, with Type 904 in the foreground. (R. Cheung)

Type 965 radar (AKE-1 antenna, seen from behind). The "candlesticks" on the yardarms are UHF radio antennas, in this case either receiving or transmitting (the double candlestick carries both antennas). (Author)

A third alternative, the U.S. SPS-6C, was considered but rejected.

The 2-array version was developed to meet a 1957 Staff Requirement for a radar-picket/missile-destroyer set, using the Type 965 transmitter and a new antenna. This version was to have been capable of detecting a Canberra bomber flying at 70,000 ft at 200 nm (150 could be accepted), with a 10 rpm data rate. The proposed antenna was about 24 $\times$ 20 ft (weight no more than 2 tons, probably 1–1.5 tons). If the aerial were not ready in time, the existing 965 (small-ship air-warning) could be used temporarily. The Staff was not happy with the Type 965 beam (17-deg beamwidth), wanting 2 deg. DND wanted no more than 10 deg.

It appears that the choice was to feed each of the 2 superimposed arrays in AKE(2) to a separate receiver (channel) and, in effect, to compare the 2 so that the result lay somewhere between the broad beam of the original 965 and the narrower beam achievable by 2 antennas side by side.

Type 965 is being superseded in British service by Type 1022.

◆ Type 967/968

Type 967:

Band: L (1260–1360 MHz) **Beam:** 4.6×68.6 deg (est)
Peak Power: 50–60 kW **Pulse Width:** 6 microsec
PRF: 7320 staggered

Type 968:

Band: S (2950–3040 MHz) **Beam:** 2×30 deg
Peak Power: 3 MW **Gain:** 30 dB **Pulse Width:** 2 microsec
PRF: 750 pps **Scan Rate:** 30 rpm (max)
Antenna Dimensions: 4 $\times$ 1 m

The Sea Wolf search-and-acquisition radar consists of 2 units arranged back to back that designate to the Type 910 target tracker. Type 967 is an L-band pulse-doppler air-search radar; Type 968 is an S-band radar for low air cover and surface search. The Type 967 antenna contains the IFF interrogator. Signals from both radars are fed into a common Ferranti FM 1600B computer, which evaluates targets, decides to engage, and feeds target coordinates into the tracker.

The antenna mounting is fully stabilized, and detection and tracking are automatic.

In 1987 Type 967M was described as a special self-adaptive pulse-doppler radar for automatic detection of small targets.

These systems are manufactured by Marconi.

Type 968 is basically a repackaged 992 with a different antenna; Type 967 is a pulse-doppler radar comparable in principle to SPS-58. This system uses a Ferranti FM 1600 series computer for track formation, threat evaluation, and director assignment. It has an integral IFF. In the new "Duke"-class frigates (Type 23), the more compact 996 was selected over 967/968.

Back-to-back Type 967/968 radars at the masthead of the British Type 22 frigate HMS *Cumberland*, 1990. The antenna halfway down the mast is a Type 1007 surface-search set. The flat oblong visible near the base of the mast is used to calibrate the ship's forward Sea Wolf director. The array of directional antennas surrounding the mast beneath the 967/968 platform serves the UAA-1 ESM system; several small radomes on yards are omnidirectional antennas (for IFM) for the same system. Near the base of the mast is a DS-30B gun. (Author)

◆ Type 975

Band: X **Beam:** beamwidth 1 deg **Peak Power:** 50 kW
Antenna Dimensions: 6 or 10 ft

Kelvin-Hughes's surface-search and seaward-defense radar was replaced in British service by Type 1006. Minimum range is less than 35 yd. Type 975ZW is a minehunter radar with true motion display and with provision for marking sonar contacts on its PPI. The only surviving examples are on board the Bangladeshi frigate *Umar Farooq* and the Portuguese *Cacine*-class patrol boats.

◆ Type 978/979

Band: X **Beam:** beamwidth 1.2 deg **Peak Power:** 20 kW
Pulse Width: (i) 0.1 (ii) 1.0 microsec
PRF: (i) 1000 (ii) 500 pps **Scan Rate:** 24 rpm

Obsolescent and being replaced, Type 978 uses a double cheese antenna (outfit ATZ), whose upper half transmits and lower half receives. This radar is based on the Decca 45, details of which are given above.

Type 979, first installed on board the survey ships *Echo* and *Vidal* in 1969, consisted of 978 plus an additional B-scope display.

Surviving examples of 978/979: Australia (River class, *Stalwart*, and "Ton" class), Bangladesh (*Leopard*-class frigates), Chile ("County"-class and *Leander*-class frigates), India (*Leander*- and *Leopard*-class frigates and "Ham"-class minesweepers),

Indonesia (former "Tribal"-class frigates), Malaysia (*Hang Tuah*), New Zealand (frigate *Waikato*), Pakistan ("County"-class destroyer), South Africa ("Ton"-class minesweepers), and the United Kingdom (some *Leander*-class frigates, "Ton" class, *Fearless* class).

◆ Type 982

Band: S **Beam:** 1 deg **Scan Rate:** 0–7 rpm
Antenna Dimensions: 26.5 × 3 ft

The sole surviving example of this long-range air-control radar is on board the Bangladeshi frigate *Umar Farooq*. Even so, this set makes an interesting comparison with Type 1022, which was intended to combine 982's sort of directional accuracy with long range. In British service, 982 often operated with a height-finder, Type 983, to provide a composite 3D radar picture.

Altitude coverage is limited by the "squint" of the waveguide feed: the waveguide produces, not a narrow fan beam, but rather a cone, so that aircraft at different altitudes register at somewhat different bearings. Squint results from internal reflections within the waveguide.

Range scales are 40 nm and 80 nm (accuracies 250 and 500 yd).

◆ Type 992

Band: S **Beam:** 1.25 × 15 deg **Peak Power:** 2 MW
Gain: 30 dB **Pulse Width:** 2.0 microsec
PRF: 750 pps **Antenna Dimensions:** 6.4 m
Antenna Weight: 640 kg

Data are for 992Q. The improved Type 992R has a peak power of 3 MW.

This target-indicator radar is the last of a long series of high-precision short-range S-band air-search radars. All the earlier ones had cheese antennas; but the current version, 992Q, employs a slotted waveguide instead. 992 is the target designation radar in Type 42 destroyers (working with 965/1022) and is the principal air-search radar in Type 21 frigates. In larger ships, 992 can be synchronized with other radars in pulse and in rotation, for quick correlation with their targets. 992 is manufactured by Marconi. Effective range on an air target is about 80 or 90 nm; 992 is the primary source of radar data for the AIO, since the longer-range Type 965 has such poor definition.

Type 992 was originally designed as a very high data rate set (scanning at 90 rpm) to feed the GDS 3 WDS. In service, this high scan rate turned out not to be very useful, and sets operate

Type 992 on board HMS *Ark Royal*, 1990, with the UAA-1 DF array below it. The 4 small radomes at the ends of the short yards below the antenna platform are the omnidirectional antennas of UAA-1, for IFM. The "candlesticks" on the longer yards are UHF radio antennas. (Author)

at 15 or 30 rpm. The original high scan rate may have been used only on board the *Tiger*-class cruisers, now defunct.

Work on the original version began in 1948 and was completed in 1952. Type 992Q/R is now being replaced by Type 996.

◆ Type 996/AWS-9

Band: 2850–3100 MHz **Peak Power:** 60–80 kW
Pulse Width: 1.8–2.2, 20 microsec **PRF:** 700–800 pps
Scan Rate: 12.5–20 rpm

Type 996. (Plessey)

Data are unofficial estimates.

Type 996 is the 3D S-band radar of the new Type 23 ("Duke"-class) frigate. 996 is replacing Type 992Q (target-indication radar) in Type 42 Sea Dart destroyers and on board the *Invincible*-class carriers. The carriers will be fitted with 2 radars, 1 for Sea Dart and 1 for Sea Wolf. Type 42 destroyers are fitted with a single degraded version, shared between both functions. The staff requirement (Cardinal Points Specification) called for 2 versions, 996/1 and 996/2, the total likely order (as of 1982) being 19 Type 996/1 for retrofit and 24 Type 996/2 for new Type-23 frigates. Both were conceived as 3D radars. Technical proposals for Type 996 were submitted in January 1983. The other contenders were a Marconi 1800-series dual-beam radar (reportedly using Martello height-finding technology), the Thorn X-band *Stix* pencil-beam radar with back-to-back phased-array antennas (based on Searchwater), and a version of the Signal SMART.

Plessey won the design contest in 1983; 996 is based on the Plessey AWS-5, reportedly incorporating the 3D signal-processing technology developed for the Plessey AR-320 radar. The commercial version, announced in 1985, is designated AWS-9. AR-320 uses an S-band FM pulse that scans in elevation (over a 30-deg range) by frequency-scanning. The radar determines target elevation by measuring the frequency of the reflected signal. Phase shifting is also used, so that the radar can alternate between frequency bands (the phase shifters are interposed between the serpentine feed and the antenna proper). The AR-320 transmitter operates at 125-kW peak power (average power 5 kW), and its pulses are of 2 types: 65 microsec (5 subpulses at differing frequencies) for low angles, 31.5 microsec (5 subpulses) for high angles, in each case with pseudorandom phase coding (31-bit at low angles, 15-bit at high angles). Pulses are sent at intervals of 550–3000 microsec (i.e., 0.55–3.0 millisec), depending on the elevation angle. The AR-320 array itself is much larger than that of Type 996 (5.1×4.3 m, tilted back at 10 deg, consisting of 76 slotted-waveguide arrays, and with a gain of 41 dB; beam dimensions are 1.4×1.5 deg).

Phase coding within the long pulses provides pulse-compres-

Type 996 seen from behind and below. (A. Raven)

sion operation without interfering with frequency-scanning for height-finding. Multimode operation (in this case, controlled by software) was important because 996 had to replace both 992 and 967/968, radars operating in very different modes and over very different ranges.

The radar has 3 operating modes: normal, a combination of long-range surveillance for air-picture compilation and target indication for Sea Wolf missiles (a fighter can be tracked beyond 115 km); missile mode, optimized against sea-skimmers; and long-range mode, in which power is concentrated in long pulses in the bottom beam (a maritime-patrol aircraft can be tracked beyond 150 km). There are 2 alternative frequency-management modes, and MTI processing is used to reject rain and land clutter. IFF Type 1010(5) is mounted with the 996 antenna.

Type 996 is described as incorporating Falklands experience, particularly in the provision of a moving target indicator (MTI) to detect aircraft popping up from over nearby land.

AWS-9 is the commercial version. Scan rate is 30 rpm; mast-head weight is 1090 kg, and below-decks weight 2700 kg; the power requirement is 52 kW. In the long-range mode, a maritime-patrol aircraft can be detected beyond 150 km.

◆ Types 1002/1003

These types are the standard British submarine radars. Type 1002 is the X-band (9650 MHz) radar for *Porpoise*-class and later diesel-electric submarines. Type 1003 is the standard surface-search radar on board British nuclear submarines of the *Valiant*, *Swiftsure*, and *Resolution* classes. Compared to Type 1002, 1003 omits the periscope-attack (range only) and limited-air-search features. Recent British diesel-electric and nuclear submarines are equipped with the later Type 1006 (see below) or with the new Type 1007.

Type 1002 is descended from a series of experimental postwar British submarine radars, Types 973, 1000, and 1001. They were developed to replace the late wartime Type 267PW, which used 2 separate antennas, a P-band (214-MHz) air-search (airguard, in British parlance) antenna and a separate X-band (seaguard) unit. There was no periscope ranging radar. A postwar project for an X-band periscope radar, initially modeled on the U.S. ST, led to the design of Type 973, tested in October 1951. This radar was rejected because the transmitter/receiver at the base of the per-

iscope was unsatisfactory. The next stage was to integrate Type 973 with Type 267PW (using a common control panel, but different transmitters) as Type 1000, which was tested on board HMS *Thermopylae* in November 1952. The next step was to replace both the air- and sea-search antennas of 267PW with a new X-band antenna, so that the previous pair of radar masts could be replaced by a single mast. This new set, which was intended for the first postwar British diesel-electric submarines, was designated Type 1001. Type 1002 has better range accuracy and uses a new display and ranging system.

Operational requirements, as stated in 1952, were: detection of a 15-m² air target at a range of 8 nm at 5000 ft (the requirement had been 15 nm at 10,000 ft); bearing accuracy of 0.25 deg; range accuracy (for the periscope radar) of 25 yd at 6000 yd, with information transmitted directly to the torpedo's fire-control computer. The main antenna was not to exceed 4 ft in width, and it was to be stowable while the submarine proceeded at periscope depth at 12 kt. In 1952 it was expected that the 4 ft × 8 in cheese antenna, which would be tilted up at an angle of 3 deg, would have a gain of 33 dB.

◆ Type 1006

Band: X (9445 MHz) **Beam:** (a) 1 × 18 deg (b) 0.75 × 18 deg
Peak Power: 25 kW **Gain:** (a) 31 dB (b) 34 dB
Pulse Width: (i) 0.8 or 0.25 (ii) 0.75 microsec
PRF: (i) 1600 (ii) 800 pps **Scan Rate:** 24 rpm
Antenna Dimensions: (a) 2.4 m (b) 3.1 m

The navalized Kelvin-Hughes 19/9A replaces Type 975. Type 1006 was developed beginning in 1969, in response to an Ad-

miralty request for a solid-state successor to vacuum-tube systems, with sea trials in 1970 on board HMS *Grenville* and *Otus*. Production began in 1971. This radar is now being replaced by Type 1007.

Both antennas, Outfits AZJ and AZK, are slotted waveguides, and there is also a submarine version. The PPI can also display helicopter transponder data, for ASW. Range scales are 0.5, 0.75, 1.5, 3, 6, 12, 24, 48, and 64 nm.

◆ Type 1007

Band: X (9410 MHz) **Beam:** (i) 1.0 × 18 (ii) 0.75 × 18 deg
Peak Power: 25 kW **Pulse Width:** (a) 0.08 (b) 0.3 (c) 0.8 microsec
PRF: (a) 1600 (b) 800 (c) 800/400 pps **Scan Rate:** 26 rpm
Antenna Dimensions: (i) 2.4 m (ii) 3.1 m
Gain: (i) 31 dB (ii) 33 dB
Antenna Weight: (i) 58 kg (74 kg dual version) (ii) 64 kg

Replacement for Type 1006, Type 1007 is a Kelvin-Hughes Series 1600 + Red Pac, a navigational radar with a manual plot. Type 1007 was developed in 1971, adopted by the Royal Navy in 1984 (production began in 1986), and also bought for Norwegian *Ula*-class submarines. There are 9 range scales ($\frac{3}{8}$ –96 nm), and the radar can display target track history and guard zones; it can operate in sector-scan mode. Besides the 2 conventional slotted-waveguide antennas, there is a dual-array for use with a helicopter transponder and Outfit RBB.

Kelvin-Hughes offers an alternative 25-kW S-band transmitter for use with this radar.

◆ Type 1010

Type 1010 is a Cossor IFF interrogator (Mk X system). It can be mounted either independently or on the antenna of a radar, such as Type 965. A typical Cossor interrogator antenna, CS.381, is 3.35 m long. The combination of Types 1010 and 1011 supersedes the earlier interrogator-transponder combination, Types 944 and 954.

A *Leander*-class frigate shows a Type 1006 surface-search radar (the slotted waveguide) below her Type 994 "quarter cheese" short-range air/surface-search antenna. The masthead array is UA-13, and below it are UA-8 and -9. The "sword" on the right just below Type 994 is a standard Anglo-American intercept antenna. This photograph was taken in 1986. [Author]

Some British warships carry an independent IFF interrogator, Type 1010. This slotted waveguide is visible atop the mainmast of a *Leander*-class frigate. The radome alongside contains a SCOT satellite antenna; below it is a Corvus chaff launcher. [Author]

◆ Type 1011

Type 1011 is an IFF transponder (Mk X system).

◆ Type 1013

Type 1013 is a lightweight, nonmagnetic IFF Mk X transponder, the Royal Navy version of the Cossor IFF 2720 airborne set. Type 1013 is carried by British minecraft.

◆ Type 1022

Type 1022 was described as a STIR, a combined Surveillance-and-Target-Indication Radar, to replace both 965 and 992Q.

Type 1022 on board HMS *Ark Royal*, 1986, seen from below and behind. The squintless feed array of horns is visible. [Author]

Type 1022 from the front. [A. Raven]

1022 combines a new Marconi antenna with a Dutch LW-08 L-band radar transceiver. Type 1022 was first installed on board the carrier *Invincible* in 1979. An all-British STIR, Type 1030, was scheduled for operation in 1985, using a very similar antenna, but that STIR was canceled, with the associated Sea Dart Mk 2 (GWS.31), in the summer of 1980.

The Marconi antenna is probably Outfit AZV, with a squintless feed (an array of 40 feed horns) and a single-curvature reflector. Beamwidth is 2.3 deg (the vertical beam is csc^2). The feed is derived from that of the land-based S625 radar, although the reflector is different. Reportedly, Type 1030 would have used 2 such antennas arranged back to back, and a single-sided Type 1031 was proposed. This antenna was first tested on board the frigate *Grenville* and was first installed on board the Type 42 destroyer *Exeter* (the first Batch-II ship) in 1978.

◆ MESAR

MESAR is an ARE/Plessey single-array electronically scanned S-band radar. The designation means Multifunction Electronically Scanned Adaptive Radar. MESAR is an octagonal array of 1060 radiating elements, 918 of which can be elementary radiators rather than the usual phase shifters. The array is inclined at an angle of 15 deg, and the beam (3.1 deg on transmit, and 3.4 deg on receive at broadside) scans through 45 deg to each side in bearing and between -35 and $+37.5$ deg in elevation; and the array can compensate for a 15-deg roll. Individual elements are $40 \times 95 \times 10$ mm (weight 135 g).

MESAR. (Plessey Siemens)

MESAR operates over 20% of S-band, using pulse compression with a duty ratio of up to 25%. Pulses are between 0.1 microsec and 1 millisecc long (i.e., over a range of 10,000), and the pulse compression ratio is 256:1 (with an extension to 500:1 planned). Range discrimination is 30 m. MESAR can handle target velocities of up to 1000 m/sec, and clutter is rejected using coherent and noncoherent MTI and pulse-doppler processing. Target position is determined by 2-channel monopulse measurement. Each module transmits at a minimum peak power of 2 W, for a total of about 2-kW peak power. Higher power is planned.

See also TRISAR, below.

MESAR is a technology demonstrator rather than a prototype for an operational radar. Development began in 1982, and trials were scheduled for 1989. The key future technology, as reflected in the MESAR design, seems to be the active array. In theory each element of the antenna should be provided with its own receiver, for the fullest sort of monopulse operation. That provision is impractical; in MESAR, low-power microwave networks combine groups of array elements into the 16 subantennas actually used for adaptive beam-forming. Each such subarray has its own receiver controllable in both amplitude and phase, and monopulse patterns can be formed by comparing the outputs of the subarrays.

Beams are formed digitally; Plessey claims that MESAR will be unique in its ability to null (shut out) jamming signals, even in the main beam, and that MESAR can reject up to 15 jammers per face.

◆ OTH Radar

ARE has tested a shipboard OTH radar system on board the Royal Fleet Auxiliary *Grey Rover*, achieving ranges as great as 100 km. Reportedly, that range was achieved by coupling special signal processors to the ship's high-frequency radio system. HF

signals commonly propagate well beyond the horizon, and there is always some back-scatter. Reportedly, the trick is to set up an interference pattern between the outgoing and back-scattered waves. That interference might indicate the presence of a target, but apparently no ship is large enough to provide sufficiently accurate beams for much more than sheer warning.

Existing HF OTH radar arrays are far too large for ship installation; typically, too, the receive and transmit arrays have to be widely separated because wavelengths are so long that otherwise they interfere. Reportedly, the British experiments are proceeding toward a bistatic mode in which reception and transmission would be on board separate ships.

Long-wavelength radar is now attractive because it is unlikely that any stealth technology can be effective at such wavelengths. It is not clear that OTH radar wavelengths are needed, although some years ago Australian scientists claimed that the Jindalee OTH radar could surely detect incoming stealthy aircraft. It is entirely possible that the longer (but still quite conventional) wavelengths from a system that can be practicably installed on the hull of an airship would suffice. That argument was made in 1988 in support of continuing the U.S. Navy's airship program.

The British program is not a ducting or surface-wave radar, which can detect targets at but not well above the sea surface. Stealthy aircraft and missiles might well approach at high, rather than low, altitude, to enjoy the aerodynamic fruits of their design. Many navies currently use ducting to target anti-ship missiles beyond the horizon, but that phenomenon is associated with short wavelengths such as X-band.

See also the discussion of the Marconi HF radar, below.

◆ AWS-1/AWS-2

Band: S (2880 and 3020 MHz) **Beam:** 1.5×40 deg
Peak Power: 750 kW **Gain:** 32 dB
Pulse Width: (i) 0.35 (ii) 1.5 microsec **PRF:** (i) 1000 (ii) 400 pps
Scan Rate: 10–12 or 20 rpm
Antenna Dimensions: 16 ft $\times$ 6 ft 6 in **Antenna Weight:** 576 lb

These private-venture Plessey air-search radars are based on the land-based AR-1 and AR-15. The first prototype AWS-1 appeared in 1960. The very similar AWS-2 was begun in 1965, the prototype appearing in 1970; it is described as the first radar to go to sea with a digital MTI processor. Claimed range on a "small aircraft" is 60 nm.

AWS-2 is a frequency-diversity radar with modular signal processing, so that more sophisticated versions could be built up for larger ships. In the simplest form, AWS-2 had 2 transceivers feeding a single display. A more sophisticated version used a stabilized antenna. Either version could be fitted with a digital MTI signal analyzer, to compensate for ship motion and to help reject low-altitude (or overland) clutter. Plessey described the antenna coverage as gapless, from low altitude (vs. sea-skimmers) to relatively high altitudes (because of the shape of the fan beam).

These radars sometimes appear with very different antennas. The Danish *Peder Skram*-class frigates combined AWS-1 transmitter-receivers with different Selenia antennas fore and aft; in their case, the antennas are cross-connected so that the ship can

The Ghanaian corvette *Kromantse* uses AWS-1 as her air-search radar. The small slotted waveguide serves a Type 978 navigational set. This ship and her sister are armed with single 4-in and 40-mm guns and with Squid. (U.S. Naval Institute)

CWS-3 antenna. The minelayers have CWS-2, whose antenna resembles that of the Italian RAN-10S but is wider. (U.S. Naval Institute)

continue to use both in the event 1 transmitter breaks down. The Danish fishery protection frigates use a single AWS-1 with a Selenia antenna. The Chilean *Almirante Riveros* has AWS-2 feeding the old slotted waveguide antenna originally installed for her Marconi SNW-20 radar. These ships have AWS-1 (with the standard antenna) aft.

◆ AWS-4

Band: S **Beam:** 1.9×30 deg
Pulse Width: (i) 1 (ii) 0.3 microsec **PRF:** (i) 680 (ii) 1360 pps
Scan Rate: (i) 10 (ii) 20 rpm **Antenna Dimensions:** 3.8×0.8 m
Antenna Weight: 990 lb (unstabilized version) or 2640 lb (stabilized version)

AWS-4 is a further development of the AWS-1 series with a new antenna, a wide-band tunable magnetron transmitter, and pulse compression. There are 2 receivers, 1 matched to plot extractor requirements and 1 with various ECCM fixes. The radar can also be fitted with 2 parallel transmitters, for frequency diversity. AWS-4 was intended to provide AWS-2 performance at half the weight. Claimed detection range is 80–110 km on a 4-m² helicopter, using the long pulse (maximum range).

The Danish frigate *Herluf Trolle* shows 2 different air-search antennas, manufactured by Selenia for an abortive RAN-7S radar, but serving Plessey AWS-1 receiver-transmitters. In Danish service these radars are designated CWS-2 and -3. The fire-control radars are Signaal's M-46s. (U.S. Naval Institute)

Using the short pulse for best resolution, AWS-4 can detect the same target at 85 km (height 9000 rather than 12,000 m).

Combined with the Type 993 antenna, this radar forms Type 994; and combined with the World War II Type 293 antenna, AWS-4 forms the commercial Type 294. There is also a light-weight (450-kg) linear-array antenna for installation in fast patrol craft (as AWS-4B). Maximum range is 70 km (8200 m target altitude). AWS-4BH has a high data rate (1 sec, i.e., 60-rpm scan rate) to detect sea-skimmers; typical aircraft detection range is reduced from 54 to 24 nm. It has a noncoherent digital MTI processor.

As of 1990, the old quarter-cheese antennas of existing Type 994 radars are being replaced by AWS-4 antennas.

This radar is currently in service with the Royal Navy, the Royal New Zealand Navy, the Royal Norwegian Coast Guard, the Sultan of Oman's Navy, the Republic of Kenya Navy, and the Royal Canadian Navy. Britain and New Zealand use Type 994.

◆ AWS-5

Band: S

Beam: High beam is 1.5×30 deg, directed upward at 45 deg; low beam is 40 deg wide in elevation, directed upward at 5 deg. AWS-5B antenna: 1.5×32 deg (azimuth squint less than 1 deg over the operating range).

Peak Power: 58 kW (mean power 1.3 kW)

Pulse Width: (i) 0.4 (ii) 20 microsec (typically transmitted in sequence) **PRF:** 1100 pps

Scan Rate: 15 or 30 rpm **Antenna Weight:** 2640 lb

AWS-5 at the foremasthead of the Danish frigate *Peter Tordenskjold*, with a NATO Sea Sparrow fire-control radar (Mk 91) aft. The 2 slotted waveguides are probably Decca TM 1229s (Skanter 009). (L. Van Ginderen)

Transmitter data are estimated from those of the Watchman ground radar (see below).

AWS-5 incorporates a new dual-beam (high- and low-cover) stabilized antenna, essentially the AWS-4 double-curvature unit plus a squintless linear array canted back to provide cover above 60-deg elevation. With the low beam, a 4-m^2 target can be detected at about 85 nm and 50,000 ft; a 0.1-m^2 target (such as an antiship missile) at about 40 nm and 25,000 ft. Like AWS-4, AWS-5 is a pulse-compression radar (for good range resolution). Pulses are coded for clutter and jamming resistance. AWS-5 has programmable frequency agility, and the IFF is integrated with the main antenna (IFF signals are fed directly into the antenna). The transmitter is coherent, so the radar can extract digital MTI information from returning pulses.

There are 2 pulse lengths: 0.4 microsec for high resolution, and a longer 20-microsec pulse that is compressed to 0.4 microsec on reception. The 2 signals are separated by using a different frequency for each.

The TWT transmitter allows for considerable frequency diversity. One advantage of the dual-beam design is that the high beam is clutter-free: unlike a conventional fan beam, the

high beam does not touch the sea. Processing features include skew correction for fast targets (i.e., correction of the error in bearing because of the motion of the antenna while the echo is returning).

AWS-5 is available in 3 basic versions: medium-power, AWS-5(MP); high-power, AWS-5(HP); and long-range, AWS-5(LR). The MP version has an instrumented range of 240 km; the high-power version uses the more powerful AWS-9 transmitter; and the LR version uses a high-gain, linear-array antenna for target indication to 200 km and long-range surveillance to 400 km. The MP version uses the same transmitter as the Watchman coast-defense radar. It has 3 operational modes: target indication for a point-defense system, and medium- and long-range surveillance. All antennas are stabilized, and all of the radars have ADTs with a capacity of up to 250 tracks.

AWS-5A was sold to the Danish and Nigerian navies. A light-weight version, AWS-5B, employs a stabilized linear array antenna (1280 lb, 1.5×32 -deg beam). Claimed performance: detection of an aircraft at 40 nm at 100,000 ft. AWS-5C is a land-based version using a low-beam horn and reflector (range 60+ nm, because of the higher gain of the antenna, and elevation up to 40 deg). AWS-5D is a stabilized version of AWS-5C for ship installation, with 2-speed scanning.

Development began in 1972, and design work in 1975, when the radar was announced. These radars have been installed on board Danish *Nils Juel*-class corvettes and 1 Nigerian frigate. The new British Type 996 (AWS-9) is partly based on this radar.

◆ AWS-6 (Dolphin)

Band: C **Beam:** beamwidth 1.5 deg (See below.)

Peak Power: 49 kW **Gain:** 29/26 dB (low/high beams)

Pulse Width: 0.1 and 4.3 microsec **Scan Rate:** 30 or 60 rpm

Antenna Dimensions: 2.6 m wide [102 in]

Antenna Weight: 520 kg, including mounting [1150 lb]

AWS-6 (Dolphin). (Plessey)

Like AWS-5, AWS-6 is a dual-beam frequency-agile radar that uses a coherent (TWT) transmitter. Its beam is narrow enough for target indication, and the radar can be used for that purpose in conjunction with a very long range air-search set. The transmitter has a very broad band frequency agility. Radar contacts are automatically extracted, using CFAR processing. The pulses are frequency-coded and pulse-compressed; a high pulse-compression ratio was chosen for better target detection in chaff. The long pulse width listed above (4.3 microsec) is a frequency-swept pulse for target indication; the short pulse is for navigation and splash spotting. There is also an optional long-

range mode using a 10-microsec pulse, in which the radar scans at 30 rpm. Pulse patterns include fixed frequency, scan-to-scan frequency agility, burst-to-burst agility, and pulse-to-pulse agility. There are 4 operating modes: 2 for antimissile defense, and 2 for extended-range surveillance using the optional 30/60 rpm dual-rotation-rate version of the basic radar.

The main reflector is center-fed by a squintless linear array, as in Type 1022; a second squintless array provides a high beam. This combination provides much smaller sidelobes than a conventional horn-fed reflector because radiation at the antenna edges is better controlled. The manufacturer claims further that the use of independent beams makes jamming difficult, and that random frequency agility forces the jammer to spread out its power. The main beam of the radar covers all angles between 0 and 20 deg, with csc² shaping up to 40 deg. The separate illuminator extends coverage to 70 deg of elevation. The antenna as a whole is stabilized against roll (within 25 deg) and pitch (within 10 deg). Total weight of antenna and mounting is 520 kg; below-decks weight is another 1340 kg [2953 lb]. Average power input is 21.9 kVA.

Under the designation Dolphin, AWS-6 is part of the Plessey-Contraves Seaguard anti-aircraft system (see the entry under Switzerland, above). A larger-antenna version (in a radome) was supplied for Danish fishery-protection vessels, and there is also a single-beam target-indication version.

AWS-6 at the masthead of the Danish frigate *Ingolf*. (Gilbert)

AWS-6 has developed into a family of 4 radars. The suffix A indicates 2 beams; B indicates a simpler radar with a single beam. A suffix number indicates relative range. All radars in the series are intended to detect low-flying missiles out to 35 km, and steep divers (at up to 70-deg angles) to 20 km; medium-range air surveillance out to 70 km; area air surveillance to instrumented ranges of 200 or 400 km (depending on model); splash spotting to 20 km; navigation to 20 km; and helicopter control. The main versions, as of 1989, are:

Dolphin scans at 60 rpm and has an instrumented range of 30 km; it has 2 beams. The tabulated data refer to this version.

AWS-6A/100 is for both Sea Guard and general search. It scans at 30 rpm for long- and medium-range search and for target indication. Once a missile has been detected, the radar scans at 60 rpm to provide an adequate data rate. Instrumented ranges are 30/70/200 km.

AWS-6A/200 is a pure search radar with a scan rate of 30 or 15 rpm and instrumented ranges of 35/70/200 km.

AWS-6B/200 has a scan rate of 30 or 15 rpm and instrumented ranges of 60/120/240 km.

AWS-6B/300 is the Danish fishery-protection radar (*Danfish*), scanning at 20 or 10 rpm, with instrumented ranges of 60/120/240 km.

As of 1989, over 30 AWS-6-series radars had been sold. Plessey attributes this success to their better-than-expected ability to track missiles.

AWS-6 introduced stripline feed into Plessey naval radar practice.

◆ AWS-7

This Plessey S-band radar was announced in 1985 as the first fully solid-state radar (i.e., using neither magnetron nor TWS) in its frequency range. AWS-7 can be supplied with either a single- or a dual-beam antenna.

The power-amplifier stage consists of 40–70 identical modules operating in parallel, each supplying 20 kW, for a total peak power of about 800 kW to 1.4 MW. The modules are mounted in a carousel, and they can be replaced even while the radar is operating. They need no special high-voltage power supply and no special liquid cooling (as is the case with a conventional single high-powered tube).

The AWS-7 designation was applied earlier to an AWS-2 with a higher-gain antenna. It attracted no sales.

◆ AWS-10

AWS-10 is TRISAR (see below).

◆ Decca TM 1226C/1229C/RM Series

Band: X (3 cm: 9410 MHz) **Beam:** 1.2 deg **Peak Power:** 25 kW

Gain: 30 dB **Pulse Width:** (i) 0.05 (ii) 0.25 (iii) 1.0 microsec

Scan Rate: 28 rpm

Antenna Dimensions: 72 in slotted waveguide (The same radar, with a 108-in antenna, is TM 1229C; beamwidth is then 0.8 deg.)

This Decca commercial pulse-compression radar is used as a small-ship search/target-indication set and as a secondary (surface-search) set on board larger ships. Decca's system is the basis of the Norwegian MSI-80S system. There is also an alternative S-band 30-kW version using a 12-ft antenna. In the designation, TM means true motion (display) and C means clearscan; 1226 means a 12-in PPI and a 6-ft antenna. Similarly, AC1629C would be an anticollision radar with a 16-in clearscan display and a 9-ft antenna. Clearscan itself is a form of clutter suppression. There are 9 range scales: 0.25–48 nm, with short pulse on 0.25 nm, short or medium on the next 3 scales, medium or long pulse on the next 3, and only long pulse on the last 2. Resolution is 10 yd on the 0.5-nm scale with a 10-m² target. Bearing accuracy is better than 1 deg.

Radars designated RM (e.g., RM1226C) show relative rather than true motion and are, therefore, somewhat simpler and less expensive. Many warships combine a TM and an RM radar.

Users (for main radars on patrol boats) include the navies of Abu Dhabi, Argentina, Belgium, Brunei, Ecuador, Egypt, France, Iran, Indonesia, Libya, Malaysia, the Netherlands, Nigeria, Norway, Oman, Peru, Thailand, and Turkey. This series is one of the world's most widely used radars.

◆ Marconi 400 Series (and Sea Cobra)

Band: X (8–16 GHz) **Beam:** 3.5 deg **Peak Power:** 2.5 kW

Scan Rate: 60 rpm in surveillance mode

Antenna Weight: 168 kg (350 kg overall)

This new series of gunfire-control radars was announced in 1983. The antenna is an offset front-fed parabola that uses vertical polarization. A frequency-agile TWT transmitter provides MTI, and tracking is by monopulse. Marconi has employed a patented method for reducing angular errors due to multipath reflection off the sea surface; that method may be similar to

Sea Cobra combines a Marconi 400-series radar with a Breda gun mount. (Marconi)

that described by Thomson-CSF in connection with Crotale Navale (see entry under SAMs below).

The transmitter is unusual in that it covers a full octave in frequency, pulse-to-pulse frequency agility over this range being used to reduce multipath effects.

In the surveillance mode, the radar scans at 60 rpm. It tracks with an accuracy better than 1 mrad in angle (RMS) and 5 m in range (RMS). Elevation is -30 to $+85$ deg.

Instrumented range: surveillance, 12 km; autotracking, 10 km. These ranges can be increased to 30 km if the radar is used to control medium-caliber guns.

The Breda-Marconi Sea Cobra integrates the Breda twin 30-mm gun with a Marconi 440 radar fire control.

◆ Marconi HF Radar

Since 1980 Marconi has been working on a long-range OTH radar that uses the ground (actually sea) wave instead of the sky (ionosphere-reflected) wave employed by more conventional OTH types. A vertically polarized HF signal will follow a conducting surface path, extending between the surface and the ionosphere. For example, it can detect icebergs as gaps in the conducting sea surface. This principle can be used both for very long range detection over the sea (from a large land site) and for shorter-range detection by a ship. Because the signal fills the space between the sea and the ionosphere, the radar can detect aircraft (such as airliners at 60,000 ft) and even low-flying missiles. Range depends on the frequency chosen, and the choice in turn depends in part on the available base length for reception. At 2 MHz, a typical range is 500 nm; at 10 MHz, this figure drops to about 200 nm. The lower the frequency, the more susceptible the radar to the movement of the ionosphere. The higher, the greater the attenuation of the signal. The appropriate balance will vary with the application.

The basic idea is not new: early World War II radars, which transmitted at relatively low frequencies, were credited with both ground- and sky-wave ranges. Similarly, wartime shipboard HF/DF sets generally detected the ground waves of U-boats transmitting beyond the horizon. The great barrier to using this physics for radar purposes was the long wavelength used by a system with a worthwhile range, hence the sheer size of the antenna required. That ceased to be a problem when electronic switching (for beam-forming) became cheap and reliable.

Some years ago Marconi, working with ARE, put receiving loops over the side of a frigate, using the usual vertical wire antennas to transmit signals. In effect, the entire length of the ship became the antenna aperture. This arrangement achieved better than 3 times the usual microwave range, albeit with less precision. As of 1989, Marconi estimates that a shipboard production version would have the following characteristics:

Transmitter Antenna:	single whip
Receiver Antennas:	8 port, 8 starboard
Mean Power:	500 W
Frequency:	3–12 MHz
Detection Ranges:	
Frigate in sea-state 4:	180 km
Fighter (low):	120 km
Small iceberg:	150 km
Accuracy:	2 km, 5 deg

A coastal site could be spread out over a larger area, and thus could operate at lower frequency. Typical parameters:

Antenna:	1000 m array
Mean Power:	40 kW
Frequency:	5–14 MHz
Detection Ranges:	
Large ship:	300 km
Frigate:	250 km
50-ft vessel:	70 km
Large aircraft (high):	350 km
Fighter (low):	150 km
Large iceberg:	350 km
Growler:	35 km
Accuracy:	2 km, 1 deg

Marconi has been operating a land site since 1980, its transmitter derived from the company's H1141 10-kW unit. As of 1989, the company regarded the ground-wave HF radar as about 2 years from development, should a customer appear; there were several possibilities, and Marconi expected that this system would be in service somewhere by about 1993. The prototype had already demonstrated an accuracy of 2 km and 3 deg, and it had detected aircraft flying at altitudes of 90–40,000 feet. On this basis Marconi saw the HF radar as a useful and much less expensive substitute for AEW radars.

Since the returning signals are necessarily weak, the bulk of the effort has gone into a combination of signal coding and signal processing. The associated computer is a DEC PDP-11 with an AP120B floating-point array processor (10 MFLOPS). Targets are detected via their doppler shifts; the processor carries out 4096-point FFTs to achieve a frequency resolution of $\frac{1}{16}$ Hz. That makes it possible to filter target velocities with a resolution of about 2 kt.

This system uses 4 transmitters to emit at a peak power of 40 kW, at 300 pps, each pulse being 200–300 sec long, to achieve sufficient average power. For aircraft signals, the radar uses an integration period of up to 16 sec (a longer period, which might make for better velocity discrimination, is impractical because the signals lose their phase coherence). A typical system would operate at 4–10 kHz, i.e., at wavelengths of about 30 m.

For a production radar, Marconi would use CW FM signals (without gaps between pulses) and a wide floodlight beam; the receiver would have 16 beams, processed in parallel (which would require a total computer power of 500–1000 MFLOPS). There would be 2 alternative displays: 1 showing the amplitude of all doppler components in a given range cell (a range cell corresponds to a set delay after transmission) or a synthetically generated equivalent to a PPI. This PPI would be refreshed every 4 sec, and it would show 3 previous positions for each target, for tracking.

A typical transmitting array would consist of 4 masts, each with a top-fed cone array. Four similar masts behind the transmitter provide a reflector; the result is a 30-deg beam, which can be slewed to cover a 90-deg sector. The corresponding receiver is 2 lines of 8 masts, for a 15-deg beam.

◆ Marconi SNW-10

Band: P (1.5 m) **Beam:** 19 deg
Peak Power: 450 kW **Pulse Width:** 3.8 microsec
PRF: 250/500 pps **Scan Rate:** 10 rpm
Antenna Dimensions: 14 × 7 ft **Antenna Weight:** 336 lb

The mattress antenna carries 12 dipoles (4 × 3) in front of a reflecting screen. SNW-10, developed in the 1950s, survives only on board the Egyptian destroyer *El Fateh*.

◆ Marconi SNG-20/21

Band: X (9200–9280 MHz) **Beam:** 2.3 deg
Peak Power: 160 kW **Pulse Width:** 0.35 microsec
PRF: 3000 pps **Antenna Dimensions:** diameter 45 in
Antenna Weight: 1400 lb

This fire-control radar is found only in the Chilean *Almirante Riveros* class. The original SNG-20 was a monopulse tracker used with a Vickers director. The Chileans replaced its original vacuum-tube electronics with solid-state units, redesignating it SNG-21; that was the naval fire-control radar displayed at ASMAR 1984. Ericsson components may have been installed in the front end of the radar about 1988–89.

The original SNG-20, details of which are given in the table above, was designed to detect targets at 35,000 yd and track them at 25,000. Minimum range was 300 yd. SNG-20 was a monopulse tracker that could search in elevation and bearing to acquire a target indicated by another radar (SNW-20). In the elevation-search mode, the radar nacelle could be scanned at 8 deg/sec. In bearing-search mode, it scanned over a 12-deg range, at 4 Hz. Range accuracy was 25 yd at 700+-yd range; range resolution was better than 100 yd. The radar could track targets moving at up to 600 kt, and range-rate accuracy was 2 yd/sec.

◆ Marconi ST802

Band: X **Beam:** 2.4 deg
Peak Power: 150 kW (100 kW at PRF 4400) **Gain:** 36.5 dB
Pulse Width: (i) 0.33 microsec (ii) 0.67 microsec
PRF: (i) 4400 (MTI) (ii) 3000 (non-MTI) pps
Antenna Dimensions: aperture 1 m (1.4 m in ST858)
Antenna Weight: director 550 kg; double-bay cabinet 690 kg; weapons-control console 450 kg

An Egyptian 6 *October*-class missile boat (with her Otomat racks empty) shows an S810 search radar (in the big radome) and an ST802 fire-control radar (atop the superstructure). (L. Van Ginderen)

ST802 is one of a series of Marconi radars (ST802, ST858 land mobile tracker, ST858 instrumentation radar, S810 and S820 shipboard surveillance radars). ST802 and S810 share a 200-kW X-band transmitter; S820 has a 400-kW S-band transmitter. All share a common digital MTI processor.

ST802 is the tracker associated with the S800-series surveillance radars (S810 and S820, below). ST802 is a fully automatic lightweight monopulse tracker; a television camera is mounted alongside. The antenna is a stabilized twist Cassegrain, and

there is a second radar channel for shell spotting. Frequency is variable over 900 MHz (i.e., about 10% of the base frequency). Peak power is increased to 200 kW in one version.

In the search mode, the radar rotates at 20 rpm, stepping upward by a full beamwidth (2.4 deg) under computer control to perform low, medium, and high scans. The radar can detect an aircraft at 10,000 ft at 20 km. If any target does appear on the target allocation panel, a button allows the radar to shift to tracking mode.

ST802 is the radar associated with the Sapphire FCS (see separate entry). There is also a land-based equivalent, ST850, and an ST858 range instrumentation radar. ST801 is an alternative version designed for direct interface with a ship's weapons-system computer. See also the Sapphire fire-control system.

◆ Marconi 805 Series

This series of privately developed tracking radars is designed for a variety of weapons: 805SW, lightweight Sea Wolf (adopted by the Royal Navy as Type 911); 805SD, lightweight Sea Dart; 805AS, Aspid; and 805SS, Sea Sparrow. Each radar can also control medium- and small-caliber guns. 805SW is a dual-frequency tracker that includes a missile command link. 805SD is a tracker-illuminator incorporating Type 909 and S1800 series components. 805AS was developed in cooperation with Selenia and uses a Selenia illuminator; 805SS uses a Raytheon illuminating transmitter and can control either vertically or horizontally launched missiles.

◆ Marconi S810/S811

Band: X (8.6–9.5 GHz)
Beam: 2.2 × 25 deg (S810P: 2.2 × 4.7 deg; S810: 1.5 × 25 deg beam with alternative 1.8-m antenna)
Peak Power: 180 kW (MTI: 135 kW)
Gain: 29.5 dB (S810P: 33.5 dB)
Pulse Width: 0.67 or 0.33 microsec
PRF: 1500 (4400 for MTI) pps **Scan Rate:** 24 rpm (S810P 40 rpm)
Antenna Dimensions: 1.2 m wide (radome diameter 1.7 m; 2.3 m with 1.8-m antenna)
Antenna Weight: 250 kg at masthead (plus 695 kg transmit/receiver)

This lightweight surveillance radar is used on board the Egyptian *October* class (Egyptian-built Komars). The antenna is mounted inside a radome. There is an alternative 1.8-m radome

Marconi S810, without its radome. (Marconi)

[1.5-deg beam, masthead weight not including radome 300 kg rather than 180 kg).

MTI is by a double canceler using shift register storage, i.e., by pulse-to-pulse comparison. In this mode PRF is staggered around 4400 pps to eliminate blind speeds. Instrumented range is then either 10 or 20 km. The transmitter is a tunable magnetron, the operating frequency being motor controlled (i.e., the transmitter is not frequency agile but is adjustable).

S811 is a version without provision for MTI.

Estimated ranges against a 5-m² airplane: 28 m at 2000 m altitude (1.2-m antenna), 20+ km at 6000 m; with a 1.8-m antenna, 32 km at 3000 m and 25+ km at 8000 m. S810P (for better low-altitude coverage) will detect a 0.1-m² target at 15 km.

These radars were announced about 1974.

The companion large radar (S820) did not sell. See the last edition for details.

♦ Marconi ST1802

Band: X (8.9–9.5 GHz) **Beam:** 2.4 deg
Pulse Width: 0.67, 0.3, or 1.0 microsec
PRF: 3000 (non-MTI); 4400 (MTI) pps
Peak Power: 50 kW (average 150 W) **Gain:** 37 dB
Antenna Dimensions: aperture 1 m
Antenna Weight: 550 kg (director weight)

ST1802 is the weapons-control radar for the S1800 series of small-ship weapons systems. ST1802 employs a fully coherent (TWT) transmitter (for pulse-doppler MTI) and enjoys truly random frequency agility. MTI can be switched on and off; presumably that selectability means there are alternative high and low PRF modes, corresponding to the 2 rated tracking ranges given below.

Data above apply to the 1802AS radar, for Aspide missile control (part of the Albatros 10/0 system), which employs a twist-Cassegrain antenna and a side-mounted television tracker. The radar uses monopulse tracking, and the CW guidance beam is injected directly into its antenna. Maximum tracking range is 40 km (24 km if MTI is used), and maximum slewing rates are 120 deg/sec in train and 50 deg/sec in elevation. Continuous elevation rate (for target acquisition from a 2D search radar) is 20 deg/sec. Elevation limits are –30 and +85 deg. Above-decks weight is 550 kg, plus a total of 1200 kg below decks (including a 650-kg transceiver and processor). These data were released in 1985.

ST1802SW is a Marconi commercial Sea Wolf director radar; at 1900 kg, it is about half the weight of the 805SW that became the Royal Navy's Type 911. Even so, ST1802SW's characteristics are a measure of the requirements imposed by the Sea Wolf system. The tracker uses a gregorian offset feed and is mechanically counterbalanced (for quick tracking) by an optronics head.

ST1802 fire-control radar, with optronic backup. (Marconi)

ST1802SW. (Marconi)

The separate missile-command transmitter, in a drum-shaped radome, is on the antenna's left side. Antenna and transmitter characteristics match the figures above. Acquisition range is 32 km against a 3-m² target, and 13 km on a 0.1-m² target.

The associated thermal imager has a 3 × 2-deg FOV.

A Samsung-built version of ST1802 equips some Korean frigates (*Ulsan* and *Donghae* classes).

♦ Marconi ST1805SW Multifire

This advanced Sea Wolf tracker, conceived as a phased-array version of Type 911, was originally developed as part of the British GWS 27 program, now canceled. Multifire is now (1988) a Marconi private venture. ST1805SW operates at X-band (3 cm), using 5000 phase shifters to form an agile 1.5-deg beam scanning through 45 deg. The stabilized antenna itself can elevate to scan from the zenith down to the horizon. This radar might be used either for low-altitude surveillance or as a multiple target illuminator for semiactive missiles. Total weight is 4500 kg (1500 kg above decks).

♦ Marconi S1810

Band: 3 cm (X-band: 8.6–9.5 GHz) **Beam:** 1.1 × cos² 5–30 deg
Peak Power: 50 kW **Gain:** 36 dB (midband)
Pulse Width: (i) 2 microsec compressed to 0.1 microsec (chirp);
 (ii) 1 microsec for air search; (iii) 0.2 microsec for surface search
PRF: (i) 2000 (ii and iii) 4000 pps
Scan Rate: 24 (standard, with radome) or 20/60 (lightweight, no radome) rpm
Antenna Dimensions: 2.44 × 0.84 or 1.2 × 0.42 m
Antenna Weight: 640 or 250 kg

S1810 is a small-ship frequency-agile surveillance radar intended for use as part of an S1800 series integrated weapons system. This radar can also be used for coastal surveillance. Typical detection ranges are: aircraft at 45 km (limited by the horizon) and small surface craft at 30 km; free space detection range is 60 km. Marconi claims that the radar can easily detect low-fliers and surface-skimming missiles well beyond engagement range. The lightweight (GRP sprayed with a metallic coating) antenna is fully stabilized.

Beamwidth data refer to the larger antenna. The smaller antenna, referred to as a compact system, scans at 24 rpm. Both the standard and the compact radars are housed in spherical

The Egyptian patrol boat *El Yarmouk* shows a Marconi S1810 radar in a radome on her foremast and a Cygnus jammer in the smaller radome on her mainmast. At her fore masthead she carries Cutlass and Matilda ESM, and she also carries 2 Protean chaff mortars. (L. Van Ginderen)

Racal-Decca 2459 F/I radar on board the Dutch replenishment ship *Poolster*. (Racal)

radomes. The TWT transmitter is capable of both pulse-burst agility and pulse-to-pulse agility; the transmitter can also be turned on and off easily, to permit radar silence without losing the ability to switch back on. Signal processing includes digital MTI, and the ship's motion (including velocity) is automatically compensated for.

ECCM features include low sidelobes, frequency agility, the ability to discriminate between signals of different PRF (as well as variable pulse length and PRF, and PRF stagger and jitter), sector transmission, a wide-dynamic-range receiver (with image rejection mixer), instantaneous automatic gain control, Dicke fix, and forward or reverse swept gain.

S1810 is the primary radar of the Egyptian *Ramadan* class. It also equips 2 Korean *Ulsan*-class frigates and some of the *Donghae* class. The S1800 radar series was first publicly discussed in 1978.

◆ Marconi S1820/1821

This S-band search radar uses a TWT transmitter for coherence (digital MTI) and frequency agility; pulses are compressed, so that peak power is only 20 kW (average power is 800 W). S1820 is the minimum configuration, with a 2.4-m stabilized antenna, and dual rotation rates. S1820 is the minimum configuration in the series. S1821 has a larger (4.7-m) but unstabilized antenna; S1822 has a stabilized antenna. The Canadian SPS-503 is derived from S1821. All 3 antennas have csc² coverage to 30 deg and scan at 24 rpm. Approximate ranges: 105 km for S1820, 145 km for S1822. These radars incorporate below-decks equipment originally developed for the abortive Type 1030 STIR radar, which Marconi had hoped to market as S1800. Type 1030 would have had a back-to-back antenna, to achieve a high data rate without sacrificing range.

S1826 was a derivative offered for the British Type 996 requirement. It used a Cassegrain main antenna (feed pointing forward and up into a secondary reflector) with a secondary squintless feed (slotted waveguide) antenna pointed up to achieve 70-deg coverage against high divers.

◆ Racal-Decca 2459 F/I

Band:	S (3.2 cm)	X (10 cm)
Beam:	2 × 30 deg	0.8 × 20 deg
Peak Power:	30 kW	25/75 kW
Gain:	26 dB	32 dB
Pulse Width:	(i) 1 microsec (ii) 0.25 microsec (iii) 0.05 microsec	(i) 1 microsec (ii) 0.25 microsec (iii) 0.05 microsec
PRF:	(i) 825 pps (ii) 1650 pps (iii) 3300 pps	(i) 825 pps (ii) 1650 pps (iii) 3300 pps
Antenna Dimensions:	12 ft	9-ft aperture

2459 F/I is a dual-band air/surface-search and navigational radar; the designation derives from the ECM band names (F and I). Returns on both bands appear together on the single display, and a master controller feeds the most appropriate combination of processed video to the weapons-control stations, which may include both surface and antiaircraft (and helicopter control). The use of a single rotating unit (X-band antenna atop S-band antenna) saves weight on top and makes for a clear arc for both frequencies. Timing and pulse length (and gain, swept gain/sea clutter, and rain differentiation) are provided by a frequency-independent unit, both antennas feeding into a single signal processor.

The S-band beam is centered on an elevation angle of 15 deg, the X-band beam pointed horizontally (for surface search). An alternative horizontal scanning S-band antenna can be provided.

Estimated range: 25 nm on a large airplane, 15 nm on a medium airplane.

This radar, and the associated Racal-Decca Command Tactical Console and 2690 Brightrack color ARPA, were selected in 1989 (announced in January 1990) for the 4 new Spanish coastal-patrol cutters.

◆ Racal-Decca 2490/2690 Series

Band:	X	S
Beam:	(i) 1.3 × 23 deg (ii) 0.8 × 23 deg	— —
Peak Power:	25 kW	30 kW
Pulse Width:	(a) 0.05 microsec (b) 0.25 microsec (c) 1.0 microsec	(a) 0.05 microsec (b) 0.25 microsec (c) 1.0 microsec
PRF:	(a) 1300 pps (b) 1300 pps (c) 650 pps	(a) 1300 pps (b) 1300 pps (c) 650 pps
Gain:	(i) 30 dB (ii) 32 dB (iii) 26 dB	(i) 30 dB (ii) 32 dB (iii) 26 dB
Scan Rate:	25 rpm	22–26 rpm
Antenna Width:	(i) 6 ft (ii) 9 ft (iii) 12 ft	(i) 6 ft (ii) 9 ft (iii) 12 ft
Antenna Weight:	(i) 34.3 kg (ii) 44 kg (iii) 219 kg	(i) 34.3 kg (ii) 44 kg (iii) 219 kg

These radars are the natural successors to the 1629 and similar Decca radars, which are so often used on board both fast patrol boats and larger vessels. These radars can be switched with the Master Series radars (see below). Alternative forms of signal processing include ARPA (automatic radar plotting aid) and AC (true motion, i.e., anticollision). The ARPA versions can carry up to 20 tracks, acquiring targets at ranges of 0.5–20 nm and tracking between 0.25 and 20 nm. Targets are continuously tracked after they are acquired and are retained on the display for 5 out of 10 consecutive scans. Plots are extracted by

a limited-area analysis system (a preset window), the gain within the window being set according to expected target size (i.e., target strength) and the local measured noise level. The track table is assembled in true motion format.

The first 2 digits in the designation refer to the size (diagonally measured) of the rectangular raster-scan display. Like the Japanese Furuno radars described with the U.S. entries, this Racal-Decca series employs a multilevel display, providing synthetic graphics in combination with the rastered PPI. The 24-in display is monochrome; the 26-in display is in color. In both cases, the display is a standard high-resolution television type (819 lines, 64-Hz raster). The image is refreshed often enough to eliminate all apparent flicker. In place of the afterglow of conventional PPI tubes, these radars generate trails of specific duration to assist in picture interpretation. The operator selects true or relative motion, and this type of display does not "smear" when the operator changes mode, e.g., from "north up" to "ship's course up." Tracks are displayed as vectors.

Eight video maps are stored in the system's memory.

Minimum range is 30 m on a 10-m² target using the short pulse, with the antenna at a height of 4.5 m (14.75 ft). Range discrimination is 30 m on the 0.75-nm scale. Scales are 0.25, 0.5, 0.75, 1.5, 3.0, 6.0, 12.0, 24.0, 48.0, 96.0, and 192.0 (optional) nm.

◆ Racal-Decca Master Series (1290 and 1690 Series)

These X- and S-band radars preceded the 2490/2690 series. The first 2 digits indicate the diameter of the circular PPI. As in the 2490/2690, the X-band radar operates at a peak power of 25 kW and uses either a 6- or a 9-ft antenna. The S-band radar operates at 30 kW, with a 12-ft antenna. Prefixes indicate the display chosen: AC for anticollision (true motion), RM for relative motion, and ARPA for automatic plot extraction (surface ATD). The system can carry up to 20 target tracks, and up to 9 markers can be positioned to monitor the bearing of a potential threat vessel. The markers are all short constant-bearing lines pointing back to own-ship: an echo that remains on the marker is closing at constant bearing and is on a collision course. The system also easily measures CPA.

There are 10 range scales, from 0.25 to 96 nm.

Racal-Decca offers a bright color PPI, the color being used to denote echo characteristics, e.g., orange for targets, black for tracks, white for ancillary data, and red for a guard zone. This display is raster scanned using digital scan conversion (DSC) and refreshing the picture 30 times a second, so fast that the eye detects no flicker. The color PPI is bright enough to be used in daylight.

Racal 1690/9 radar equips the Dutch *Karel Doorman* (M-class) frigates.

◆ Trisar

Trisar is a Plessey development of MESAR, a rotating active phased-array radar with 3 independent active-array faces. Their pictures are integrated by software. Each face is to contain 2560 independent transmitter/receivers. No prototype has been built, but Plessey expects Trisar to be ready for production by 1994, in time to succeed Type 996. Current efforts are concentrated on reducing the size and cost of the active elements, including reducing their cooling requirements. The current (late 1989) arrangement is the quadpack, in which 1 controller runs 4 GaAs modules. Ship installation is simplified, in that the system requires neither chilled water nor a below-decks transmitter. There are no rotating high-power RF joints, and since each transmitter operates at relatively low power, the radar uses no high voltages. System reliability is increased further in that the radar can continue to function with only 1 or 2 faces.

Trisar is expected to operate over a wide range in S-band, rotating at 10 rpm. Because there are 3 faces, this slow rate (making for a good probability of target detection) is equivalent, in data-rate terms, to the 30 rpm of 996. A diagram displayed at RNEE 1989 showed a fourth (zenith) face atop the rotating array, for full hemispheric coverage. Missile uplinks (for com-

mand guidance) can be accommodated in the narrow areas between the main faces. A 3-face X-band active-array multichannel illuminator can be mounted above the main faces, a system Plessey calls TRIXAR.

Plessey argues that pointing errors in a single phased-array face (such as that in EMPAR) increase sharply as the target moves away from broadside. Providing 3 faces limits this error, because a target is never very far from the broadside position. Multiple faces also make for a high data rate at a low scanning rate. The latter increases the number of pulses hitting the target and so can reduce the effects of clutter and ECM. Plessey also claims that the very wide bandwidth and special monopulse algorithm of Trisar will improve angular accuracy. Frequency agility should also help eliminate multipath effects.

Like EMPAR, Trisar promises a combination of long-range (low-PRF) and horizon search (high-PRF) operation, in each case with the variable dwell time permitted by electronic beam steering (in a conventional radar, dwell time is determined by the rate of rotation). To indicate performance against stealthy targets, Plessey estimated radar range against a pigeon (0.008 m²: 105 km, or 57.4 nm), a sparrow (0.0016 m²: 70 km), and against a worker bee (0.0002 m²: 42 km), all in clear conditions.

Like MESAR, Trisar would overcome jamming by steering its nulls into the jamming beam.

◆ Sentinel

Marconi coast-surveillance radar is for surface and low air cover out to 30 km against a 5-m² target. It uses an S1810 antenna and a standard marine radar transceiver, probably that of the Type 1007 radar. Peak power is 25 kW (90 kW optional), and the antenna scans at 20 rpm. Pulse widths: 0.08, 0.3, 0.8 microsec (PRFs 1600, 800, 400 pps, respectively). The 2.44 × 0.84-m antenna produces a csc² beam over 5–30 deg in elevation.

◆ Watchman/Guardsman

Watchman and Guardsman are Plessey's coast-defense radars. Watchman has been selected by the British Ministry of Defence, and Guardsman has been exported. The S-band Watchman can detect a 1-m² target at 148 km (30 km at low altitude), and it can track over 100 targets simultaneously. The Watchman's transmitter is a high-powered TWT using pulse compression. Characteristics of the air-search version: peak power 58 kW; pulse pattern 0.4 microsec short pulse followed by 20 microsec long pulse (compressed to 0.4 microsec); average power 1.3 kW (implying a PRF of about 1100 pps; there is also an 840-pps mode); scan rate 12 or 15 rpm. Range on a 1-m² target is 100 or 110 nm. The air-search version uses a dual-beam antenna similar in form to early AWS-series naval radars. There are also a transportable air-search version and a coastal version with special signal processing for surface and low-flying targets.

Watchman was first ordered, for the RAF, in June 1983 (33 fixed and 6 transportable units); the first was handed over in September 1986. Current users include the Finnish air force, Bahrain, Dubai, China (PRC), Ghana, Oman, Portugal, and Spain; it is not clear whether any of these radars is being used for coastal surveillance.

The C-band Guardsman is based on the Plessey AWS-6, and in at least 1 form Guardsman uses much the same antenna as that in the Contraves Skyguard system. Scan rate, however, is 15, 30, or 60 rpm. Maximum range on a 3-m² target is 55 nm, and the beam is 1.5 deg wide.

There is also a Guardsman S, in which the Watchman radar electronics are combined with the Guardsman transportable cabin and mast. In this case the mast is 10 m high (15 m optional), compared to 9.5 m in the standard Guardsman.

RADAR INTEGRATION

◆ British Radar Plot Extractors

Radar plot extractors are, in U.S. parlance, radar-video converters. Those in current service are the Ferranti LFX and LAX intro-

duced in the early 1970s, associated with radars of Types 965, 992, and 1006. These systems are all semiautomatic: as in the U.S. NTDS, the associated combat system performs rate-aided tracking based on a series of initial plots, which the operator confirms. Further details of LAX can be found in the discussion of the British ADAWS combat system in the Surveillance and Control section of this book.

The great drawback of the British systems is that the operator must still process large numbers of individual radar contacts, deciding which subsequent ones are properly associated with earlier ones to form tracks. That association can be difficult in a very cluttered environment: hence the need for automatic correlation of individual contacts to form tracks. The Royal Navy calls such systems radar automatic track extractors (RATES), which are equivalent to the U.S. ADT.

The first experimental British RATE system was developed by Thorn-EMI and ARE Portsmouth in the late 1970s; that experiment led, in turn, to 3 production systems: LFA (for Type 996), LFB (for Type 1022, for which a contract has not yet been awarded), and LFC (for Types 1006/1007). These RATES will appear on board ships now under construction and will also be retrofitted to ships already in service. At least in the case of LFC, the system combines radar plots with information from the radar transponder (Outfit RRB) used to track the ship's ASW helicopter.

ADIMP, the ADAWS improvement program, includes a Thorn-EMI track combination system comparable in theory to the U.S. SYS series. Previously, ADAWS had selected the radar providing the best track information, rejecting all the rest.

OPTRONIC SYSTEMS

◆ DAS

Defence Equipment and Systems (Laurence Scott) director aiming sight is a line-of-sight-stabilized unit carrying a pair of binoculars, with provision for 2 other sensors (e.g., FLIR and laser range-finder) alongside the seated operator. The operator can control the training and elevating servos by joystick, or they can be slaved to the associated fire-control system. The director can also be remotely controlled. Outputs are target bearing, elevation, and range (if a range-finder is fitted), sent either directly to a gun or missile launcher, or via an associated fire-control system.

Maximum balanced sensor load is 150 kg, and total weight is 650 kg. Elevation limits are $+70/-20$ deg, and train (elevation) rates are 90 (100) deg/sec; corresponding acceleration rates are 245 (400) deg/sec². Training slew time over 180 deg (rest to rest) is less than 3.5 sec; over 60 deg elevation (rest to rest) is less than 1.5 sec. Overall height is 1.82 m, the binocular axis is 1.735 m above deck, and the swept radius is 0.64 m. Below-decks weight is 182 kg.

◆ DIMITIS

Barr & Stroud's Director-Mounted Thermal Imaging System is being developed for use on a RADAMEC Type 409 director. The imager is an IR26, a development of the earlier Barr & Stroud IR18 family. It uses a cryogenically cooled SPRITE detector (8–13 micron band). FOV is 13.6×9.1 or 4.75×3.18 deg. The sensor head weighs 19.9 kg.

◆ EOSS/Series 1000/HK 409-010/EPO 409-010

Radamec Electro-Optical Sighting System was bought by the Royal Navy for Type 22 frigates and Type 42 destroyers operating in the Persian Gulf. There is no other designation. It was first installed in 1988, the first batch of 2 being delivered in 5 months. As of the fall of 1989, 5 ships had been fitted (2 EOSS each), and 1 was still to be fitted. EOSS was initially bought to detect floating sea mines and was then used to identify ships and aircraft. It is, then, broadly comparable in role to the U.S. mast-mounted sensors installed on board *Perry*-class frigates. EOSS proved successful in Sixth Fleet exercises.

Series 1000 is the current Radamec designation for the sta-

Radamec Series 1000 electro-optical director. (Radamec)

bilized electro-optical surveillance system, which is mounted on an HK 409 dual-axis stabilized director (the HK 409 designation was used in the past). In this case the director carries a Radamec daylight television camera and a GEC thermal imager. As of late 1989, over one hundred 409 directors were in service in various navies, including over 60 in the Royal Navy. Apart from the current EOSS, Royal Navy 409s carry Series 2000 sensors (see separate entry below).

Series 1000 is itself a recent designation, but this equipment is used (under other nomenclature) by the Royal Danish Navy, by the Finnish Coast Guard, by the Hong Kong police, by the Spanish Navy, and by a Middle Eastern customer. Series 1000 is designed for surveillance and for limited fire control (it can incorporate a lead computer for 30-mm and 40-mm guns). Series 2000 (see below) is a larger equivalent, enjoying substantial commonality with Series 1000.

A typical Series 1000 director weighs 150 kg, including typical sensors; it is 0.5 m high, and swept radius is 1.2 m.

Some of the applications described as Series 1000 surveillance may be more recent versions of the EPO 429 or HK 429 first displayed at RNEE 1983, carrying a Marconi day or low-light-level camera and a FLIR. The Series 1000 fire-control device was also described as the Optical Fire Director (OFD).

The Radamec surveillance/tracking television camera is designated HK 202-002. It has a 16–160-mm zoom lens (FOVs range from 21×16 to 2.1×1.6 deg). The sensor is a CCD (6×4.5 mm) with 604×576 active elements, to produce an image with a resolution of 450 lines horizontally and 420 lines vertically (scan rate 625 lines at 25 frames/sec or 525 lines at 30 frames/sec). The boresight remains stable within 1 mrad at full zoom (10 mrad nominal) as the lens zooms. Total maximum camera weight is 8 kg. Dimensions: 178×450 mm.

Radamec also produces a low-light-level camera (HK 203-001). It, too, has a 16–160-mm zoom lens (FOVs 48×36 to 4.8×3.6 deg). It can tolerate levels of illumination from starlight to full sunlight, a dynamic range of 80 dB. The sensor is a CCD

carrying 604×576 elements; resolution and frame rate match those of the daylight camera. Maximum weight is 12 kg.

These cameras can feed an IDT 2000 video tracker (described under Radamec Series 2000, below).

Series 1000 is derived from manned fire-control directors and surveillance systems; it is a low-cost system for small vessels. Several related manned systems have recently been installed on 30-m patrol craft carrying twin 30-mm guns.

See also Radamec Series 2000, below.

Radamec was formerly Evershed Power Optics (EPO), and HK 409-010 was formerly EPO 409-010.

◆ Ferranti Electro-Optic Multi-Sensor

This is a spherical turret with 2 windows, carrying a Ferranti Type 118 laser (NdYAG, 0.4-mrad beam, 100-mJ power). It can be joystick or auto-track controlled and can be linked with a Ferranti helmet acquisition and tracking indication system (HATIS), so that targets can be designated by someone on a ship's bridge. Targets are passively tracked by infrared (8–14-micron band) and a television with a zoom lens. Typical FOVs for the latter are 8 and 30 deg. The turret is stabilized in 4 axes and can turn through 220 deg. Elevation limits are $+90/-60$ deg. The accuracy of angular (track) outputs is within 3 mrad. Laser range accuracy is 5 m. The turret slews at 1 rad/sec. Auto-tracking circuits keep the target within a 2-pixel area (150 mrad in narrow FOV). Turret diameter is 425 mm (height 520 mm); weight is 32 kg.

◆ GP250

Ferranti's new (1990) gunfire predictor is based on its Series 500 command/control system; it is the element recently sold to Denmark for coastal defense. The most basic form of the system is the predictor proper (GP250P), consisting of software resident (as EPROM) on a series of extended double Eurocards that can fit a customer's computer. The associated microprocessor in the existing GP250P is the Motorola 68020; the Eurocards fit a standard VME bus. The system is programmed in ADA, and the algorithms used are based on those developed for Ferranti large-ship systems, the 400- and 500-series.

GP250P initializes the gun system, predicts ship and target motion, filters/smooths the data it receives both from own-ship sensors (wind and log, gyro and vertical reference) and from the target tracker (e.g., a radar), and calculates aim points. The system can accommodate ballistics for guns from 25-mm up to 5-in or 155-mm. Target-track prediction is based on Kalman-filtered data, and the method of prediction can be either a straight line (SLP), goal-oriented prediction (GOP, for initial engagement of long-range air targets), or SLP with maneuver detection. The system is sensitive to pop-up targets, and it takes into account such corrections as deck movement (roll and pitch), the curvature and movement of the earth, and sensor and gun offsets (parallax). Ship velocity, wind, air temperature, humidity, and air pressure are all taken into account automatically. Splash spotting is inserted via a manual data entry, and fixed gun aim-offs can be provided for warning shots. One or more guns can be controlled.

GP250M is GP250 with full color-graphic MMI (man-machine interface).

GP250T is the total predictor, with its own operator workstation, capable of controlling the principal tracking source. This is the prediction General Processing Unit of the Ferranti WS500 (Series 500) command/control system. GP250T is GP250P plus a control/display unit, a gun synchro drive, and gun tellbacks (feedback to indicate gun status to the system).

GP250L is the land-based version for coastal defense.

◆ GSA 200/300 Series

Ferranti gyro-stabilized lead-computing sights for medium-caliber guns. In Series 200, the gunner selects 2 gyro sensitivity ranges, e.g., 1 to accommodate distances around the maximum gun range and 1 to accommodate the minimum range at which a target can be manually tracked; or 1 for computed tracking

mode and 1 for preliminary slew mode (the gyro is caged for quick slew toward the target). There are 2 displays, a fixed reticle (left-hand side) for slower targets, and as a standby, and a gyro reticle (right-hand side) for lead prediction, showing 40 and 10 mrad circles. Approximate weight is 17 lb.

Series 300 has 3 factory-preset gyro sensitivities, to suit the type of gun and ammunition (for long/medium/short ranges), plus a slew position. Ranges are selected in the sequence slew/long/medium/short, by means of a hand- or foot-push button. The displays match those in Series 200, and weight is about 17 lb.

◆ Laser Dazzle System (LDS)

ARE's laser gun is intended to dazzle, and thus to drive off, approaching pilots. Typically, 2 are mounted on tripods abaft the bridge of a frigate. They are portable and may be cross-decked. LDS was first tested on board HMS *Euryalus* in the Irish Sea in 1981, and several ships (reportedly including the 2 carriers and the frigates *Brilliant*, *Broadsword*, and *Argonaut*) carried it during the Falklands War. It may have caused the loss of several Argentine aircraft, including 1 whose pilot reported that intense glare had driven him away from an attack on HMS *Argonaut*. LDS has also been fitted to (and reportedly used by) British frigates on the Armilla Patrol in the Persian Gulf. The existence of LDS was not reported until January 1990 because of British security restrictions.

Current units may be a second-generation version directed by the Sea Wolf director; LDS seems to be associated with Sea Wolf. The advent of LDS may be associated with the shift, in the Sea Wolf system, from a combined radar/electro-optical to a fully radar-controlled director.

LDS is manufactured by Irwin Desman Ltd.

Possibly because of the existence of LDS, the official British Institute of Aviation Medicine developed antilaser goggles for pilots, using reflecting filters.

◆ NTIS/TIGS

Thorn-EMI's Naval Thermal Imaging System/Thermal Imaging Gun Sight is an application of their Thermal Imaging Common Module Class 1, which was originally developed as a direct-view night-observation device. It in turn evolved into a Multi-Role Thermal Imager (MRTI). The detector is a cadmium-mercury-telluride array (8–13-micron band) scanned across a scene in series-parallel mode; outputs are displayed by means of a scanned red LED array. The same electronic output can be fed into a television. The detector array is cooled to 80°K. There are 2 FOVs (NTIS 1: 4.3×2.8 and 11.1×7.4 deg; NTIS 2: 3.3×2.2 and 8.1×5.4 deg).

NTIS may be integrated with a director, such as Sea Archer. Weights: director and imager 100 kg, compressor (for cooling) 115 kg, console 130 kg. Total travel in azimuth is 190 deg; elevation limits are $+65/-35$ deg. Maximum slewing speed (bearing) is 120 deg/sec.

The much smaller TIGS weighs only 5 kg. TIGS FOV: 20×6.6 deg with $2 \times$ magnification, 8×3.4 deg with $5 \times$ magnification. There is also a hand-held version (HHTI) of TIGS, using hybridized modules to reduce weight.

Both NTIS and TIGS are, reportedly, in current British naval service.

Thorn-EMI is currently under contract to produce an IR naval threat warner to complement ESM systems. The naval requirement was formulated about 1987, and the device will use a dual-band detector. The near band (3–5 microns) is considered preferable in very humid weather and is used to detect missile and aircraft exhaust plumes. The far band (8–13 microns) is used to detect aircraft and helicopters by their skin friction. The threat warner includes a processor that classifies targets, prioritizes them, and indicates their azimuth to operators, automatically pointing the sight and auto-tracking in azimuth and elevation. Thorn-EMI is already developing an analogous single-band (8–13-micron) system, ADAD (air-defense alerting device), for

the British army. It is used to alert and to point hand-held anti-aircraft missiles such as Javelin. ADAD consists of a tripod-mounted scanner, a separate signal processor, and up to 4 remote terminals, typically lying on the ground near the missile operators. As of late 1989, ADAD was scheduled to enter British service in 1991.

◆ OFD

Defence Equipment and Systems (Laurence Scott) Optical Fire Director is the director chosen for the Royal Navy GSA 7 (Sea Archer) system. The operator stands on a ring around the base of the director, observing the target through a pair of binoculars, and controlling the director using a 2-axis joystick. In the alternative remote-training mode, the OFD is manually controlled in elevation only. There is also a full remote-control mode, the operator presumably acting to check the tracking of the remote sensor. Like the same manufacturer's DAS (described above), OFD can carry 150 kg of electro-optical sensors (the Royal Navy leaves the sensors on the separate Sea Archer pedestal).

Total weight is 485 kg, and overall height is 1.95 m (binoculars are 1.858 m above deck); swept radius is 0.795 m. Elevation limits are $+70/-20$ deg, and train (elevation) rate is 96 (67) deg/sec; corresponding elevations are 120 deg/sec² for both train and elevation. Tracking accuracy is better than 1.5 mrad, and MTBF is greater than 1100 hr.

Users include the Royal Navy (in OPVs), Brunei, Egypt, Hong Kong, Kenya, Nigeria, and Oman.

◆ Radamec Series 2000/HK 409-029

Series 2000 includes both fire-control and surveillance systems. Current applications include the Korean KCX/KFX corvettes and frigates and British warships. The stabilized director can carry a variety of electro-optic sensors, normally a daylight or low-light-level television (see the descriptions under EOSS/Series 1000), a FLIR, and a laser range-finder (Series 1000 lacks the laser range-finder). The video tracker is the IDT 2000, below.

Series 2000 includes an integral gun predictor, carrying ballistics in its ROM (and thus requiring no program loading prior to battle), and it can include a special Radamec lead-angle processor. Targets can be designated optically. The display console includes the tracker electronics and also the fire-control (predictor) electronics and, thus, can serve as the basis for a small-ship WCS. This system can include an optional Ka-band tracking radar. Radamec also offers a manned version, in which the pedestal carries an optical sight and, for example, a laser range-finder. The optical line of sight is motion-stabilized; a FLIR can be added (with a small monitor on top of the director).

The intelligent digital tracker (HK 250-001) or IDT 2000 is carried on a VME bus-compatible extended double Euro-card (and expected to be available shortly on an IBM PC/AT-compatible circuit board). The video signal is digitized at 10 MHz, giving 512×512 -pixel resolution. The board carries dual $128 \times 128 \times 8$ -bit (the latter for shades of gray) high-speed image memories, which can be reconfigured as $512 \times 512 \times 1$ -bit memories to cover the full FOV. Alternatively, the image may be digitized at 5 or 2.5 MHz, so that a larger (but less distinct) image may be stored. The board also carries a $256 \times 256 \times 4$ -bit overlay memory to store graphics and text. Six "areas of interest" in the image can be captured and/or processed independently. Some frequently used image-processing functions are realized directly in hardware, and the board is provided with a 20-MHz 32-bit processor and 64 kbytes of program and data memory. Outputs are Video 1 (raw video with superimposed graphics) and Video 2 (digitally enhanced video without graphics); target position and size output; servo tracking outputs; and target and scene data output to a master control processor in a multisensor application.

Besides the basic Type 409, Radamec offers 4 other stabilized director mountings: 429, 449, 459, and 469 (mirror mount; direct drive). Slewing rates are up to 360 deg/sec.

◆ ROD

Laurence Scott's Remote Optronicon Director is a remote-controlled device stabilized in line of sight. Control is by joystick, or ROD can be slaved to another director for target acquisition. ROD incorporates memory tracking for use in bad or interrupted visibility. The stabilized platform can carry 150 kg (75 kg on either side of the training head) of sensors, typically an Ericsson laser range-finder, Ericsson IR camera, and Marconi TV tracker. Total weight exclusive of sensors is 155 kg, and elevation limits are -30 and $+85$ deg.

ROD was first displayed in 1980.

A very lightweight development of the Laurence Scott ROD was announced in 1981. The director weighs 45 kg and carries a 45-kg optronic payload, typically an Ericsson laser range-finder and a Marconi LLLTV. Height is 620 mm, and typical train and elevation rates are 45 deg/sec. Elevation limits are -30 and $+85$ deg.

Like ROD, this director is joystick-controlled and can auto-track.

◆ SLC-001

This new twin-axis, stabilized, optical, lead-computing sight was announced by Astra Holdings (Laurence Scott) at the 1989 RNEE show. It is intended for 12.7-mm (0.50-caliber) to 40-mm guns. SLC-001 automatically computes the lead in both azimuth and elevation and projects them electronically in the form of a cross wire in the gunner's FOV. The gunner can select a fixed display for a stationary target. Because SLC-001 operates electronically, Astra claims that it shows significantly less recovery and prediction time than electro-mechanical sights. It also requires fewer precision parts, and Astra estimates that it should cost only a quarter to a third as much as a conventional sight (which costs £ 15,000–20,000).

The sight can be powered either externally or by its own 4-hr battery. The battery cuts in automatically when external power is lost, and in this case the usual electronically generated display is replaced by a fixed-graticule display. The sight is aligned to the gun boresight by a dovetail fitting, which slides into a universal alignment bracket, and is clamped by 2 thumb-screws. The FOV is 50×17 deg, and the aperture is 100×35 mm. Focal length is 75–100 mm. SLC-001 incorporates Reactolite Rapide optics, as are used in commercial sunglasses that react to changes in light level. In the sight, the effect is to darken a very bright sky so that the bright graticule generated within the sight remains clearly visible. Other sights use pop-up filters.

Total weight is 3 kg.

The SLC-001 lead computing sight on a 20-mm gun. (Astra Holdings)

As of September 1989, development was almost complete, and Astra hoped that its sight would be tested for application to the new British twin 30-mm gun. Chile and Ireland had also shown interest. SLC-001 began Royal Navy tests in May 1990. The Royal Navy has asked that the sight be arranged so that its ballistics can easily be changed (the sight might be shifted from weapon to weapon). That is done by changing the gain of the internal amplifier (which is used to compute the lead angle); the production sight will presumably incorporate a switch controlling the amplifier. SLC-001 may also be coupled with a thermal imager and with a laser range-finder in future.

♦ TDS

Target Designation Sight, manufactured by Defence Equipment and Systems, Ltd. (formerly Laurence Scott). TDS is the standard Royal Navy target designator, comparable in function to the U.S. Mk 24. It is also in service with 9 other navies. The head, to which a standard pair of binoculars is fitted, is counterbalanced for easy tracking in elevation, and height can be adjusted to suit the operator; an illuminated bearing scale atop the pedestal allows the operator to align the sight with a given target bearing. The target-designation switch is in the right hand grip. The pedestal (less binocular) can be extended from 1.52 to 2.03 m in height, and swept radius is 0.3 m; total weight is 77 kg. Training limits are ± 170 deg, and elevation limits are $+85/-15$ deg. Transmission accuracy is ± 30 minutes of arc.

The Laurence Scott LASS (Look-Out Aimer Stabilized Sight) has been made for the Royal Navy since about 1964.

♦ V3800

GEC Sensors thermal imager is part of the Ferranti fire-control system for 4 new Brazilian corvettes, and also for Seaguard, for Thai naval systems, and for Hong Kong patrol craft. It is based on the UK Thermal Imaging Common Module Class II (TICM II), and has a zoom lens (2×3 –to 8×12 -deg FOV). TICM II uses a SPRITE detector and operates in the 8–13-micron band, with alternative FOVs (60×40 deg, for 625 lines at 50 Hz, or 48.4×32.5 deg, for 525 lines at 50 Hz). Resolution is 2.27 mrad (60-deg FOV), and pupil diameter is 10 mm. The detector uses 8 parallel CMTs. The scanner head weighs 9.5 kg.

FIRE-CONTROL SYSTEMS

♦ FPS 5

This Flyplane Predictor System, developed as an interim alternative to MRS 3, survives on a few ex-British frigates. It can be recognized by the presence of a large Mk 6M director carrying the twin nacelles of the Type 275 radar. The original Mk 6 was considered inadequate, and Mk 6M was entirely different in configuration. Unlike previous British directors, which measured the direction to the target (goniometry), Mk 6M followed U.S. practice in measuring target rates of motion (tachymetry). Also unlike Mk 6, Mk 6M had no optical range-finder, although it did have a dome for the Director Officer. All-up weight was 3 tons less than that of Mk 6 (total 8 tons, 5 of it revolving weight). Targets could be indicated either blind or visually.

Elevation limits are $+75/-15$ deg. The anti-aircraft predictor (computer) can handle range limits of 500–15,000 yd, and shell time of flight of up to 30 sec. Target speeds can be up to 700 kt (70 kt for surface targets). The tracker can handle rates of train and elevation up to 10 deg/sec; the predictor (GRU) can generate 45 deg/sec in bearing and 25 deg/sec in elevation. Maximum effective range of the associated 275 radar is 36,000 yd.

There was also an FPS 3, now extinct, with very similar components.

♦ GDS Series

These Gun Direction System designations were applied at the end of World War II. GDS 2 was the standard destroyer system. Particular GDSs were associated with Target Indication Units (TIUs) and with particular radars. In theory, a GDS was the basis

of an integrated gun-control system, with a target designation display on the bridge or in the operations room. These concepts carry over directly to the later GSAs and WSAs. Similarly, a GDS would correspond to the somewhat later U.S. WDS, each having a limited number of analog target-tracking channels. GDS 2* survives on board old ex-British frigates equipped with FPS 5 fire-control systems. The few even older ex-British destroyers equipped with Mk 6 directors are probably fitted with GDS 2.

In each case, the TIU provided a form of TWS performance to the basic target indication (i.e., short-range air-search) radar, and insufficient data rate (to handle fast aircraft) was a major problem.

In this series, GDS 1 was the old visual-only system.

GDS 2 used Radar Type 293. It was associated with TIU 2, which could handle 3 or 5 targets simultaneously.

GDS 2* used Radar Type 293Q; it was also associated with TIU 2. GDS 2* was conceived as an interim system pending the development of the ultimate GDS 3, to be available in time for installation on board the new postwar frigates. GDS 2* was ultimately limited because Radar 293 could not rotate at any rate higher than 30 rpm (and more commonly at 15 rpm). For 400–600-kt targets the preferred data rate was 1 sec (60 rpm) or less. GDS 2* could detect a medium bomber at 55,000 yd and a fighter at 35,000 yd; net accuracy was 2 deg in bearing and 150–400 yd in range. It used 2 operators, 1 for range and 1 for bearing. The blind indication channels fed directly to the weapons systems.

GDS 3 used Radar Type 992; it was associated with TIU 3 (4 or 6 channels). GDS 3 was chosen as the ultimate GDS in 1948. Unlike 293Q, 992 could scan at 90 rpm. A medium bomber could be detected at 70,000 yd and a fighter at 45,000 yd; accuracy was $\frac{3}{4}$ deg and 200 yd, irrespective of range. The system incorporated auto-following circuits (which could not function in heavy clutter; operators used joysticks under such circumstances to track targets). Target channels could be flexibly assigned to various weapons. GDS 3 was massive (it weighed 19 tons, compared to $4\frac{1}{2}$ tons for GDS 2*, and cost £ 148,000 in the early 1950s, compared to £ 25,000 for the simpler system). It was a prerequisite for successful Sea Slug missile operation. A 6-channel version was tested in 1956, and GDS 3 was the British equivalent of the early U.S. WDS, for the first series of County-class destroyers. In effect, it was replaced by ADAWS. GDS 3 was used largely for missile control, although it was installed on board the 3 *Tiger*-class cruisers.

Type 992's effective range was 25–30 nm, but the original Sea Slug required radar data out to 100 nm, despite its much shorter range. The existing small-ship air-search radar, 965, had too broad a beam to provide sufficient long-range detection. Two Signaal radars, LW 02 and VI-01, could have provided sufficient performance, but they were rejected because of the expected cost of Anglicizing them. In theory, given a target approaching at 600 kt, the missile system required 15–40 nm for evaluation and 10–30 nm for target indication to the Type 901 fire-control radar, for a total of up to 70 nm before the Sea Slug missile could be fired.

When the County class were designed, there was little hope of providing them with better radar coverage, and the proposed solution was DPT, the digital plot transmitter. Destroyers would operate in company with a ship carrying a high-capacity 3D radar (Type 984), which would transmit its plot data to consoles in their operations rooms. The carrier would have a computer track-keeping system, CDS (the comprehensive display system), but the destroyers lacked any corresponding computer; they acted as out-stations of the carrier's CDS. At best, CDS could carry 48 tracks, to an accuracy of 1:1000. Each track was specified by a number (1–48), a category (1–9), a raid-size indicator (1–9), and an altitude (2 digits, for height in thousands of feet), plus X and Y coordinates. Each missile destroyer had 2 intercept positions, which could use CDS data to cue the Type 901 missile-engagement radar and increase the available engagement time by 15%. The CDS track repetition rate, equiv-

alent to a data rate, was 20 targets/sec, i.e., a data rate of 2.5 sec on each target.

This solution was adopted partly because the DPT reception consoles and other equipment were much the devices that would later be needed for the successor system, then (1955) called DTE, or digital translation equipment. DTE was, presumably, the terminal associated with the digital ADA system, which replaced CDS. It required a digital computer on board the destroyer. The DPT solution was adopted for the first series of County-class missile destroyers, which never were fitted with tactical-data-system computers. The great limitation of the system was that it used a line-of-sight (UHF) data link, so destroyers had to remain within 12 nm of the parent carrier. There was also some question about the timeliness of CDS data; processing was slow because there were (in the 1955 version of the system) 4 operators who could process 2 targets per minute. Thus, individual plots could be as much as 6 minutes late, far too stale to be accurate as a target came within 992's range.

In 1955 the British also considered an alternative plot-transmission system, the Dutch Teleplot. It automatically displayed raw radar video to plotters over a VHF analog link. Teleplot was probably fitted to contemporary Dutch warships.

GDS 4 was an abortive system, intended to meet a 1949 Staff Target for a system capable of providing a 3D solution to fire-control problems, with complete sky cover up to 50,000 ft. The associated radar was an unspecified TWS type, and GDS 4 was considered superseded by the 2D GDS 3. It was canceled in 1955.

GDS 5 was the intended successor to GDS 2*, using a 293Q or 992 radar, and TIU 5 (3 or 4 channels). Originally, 2 other radars, the U.S. SPS-6C and a new Type 976 (a composite air/surface/gunnery set), were alternatives. GDS 5 was planned for installation from 1958 on, using a new universal PPI scope, and 3 operators with electronic markers who could designate targets to specific weapons. Thus it was similar to the simpler U.S. TDS systems. This is the GDS employed in British frigates and missile destroyers prior to the adoption of automated digital systems such as ADAWS and CAAIS. For example, GDS 5 survives on board the Pakistani County-class destroyer and Indonesian Tribal-class frigates. The radar in the Indonesian ships is 293Q; in the Pakistani ships, 992.

◆ GWS 20/21/22

These are Sea Cat directors of increasing sophistication. GWS 20 carries only a pair of binoculars. The aimer elevates and trains the binoculars, and 1 of the pistol grips carries a joystick

Sea Cat and 2 of its guidance systems: the launcher, with missiles, is at left; the GWS 22 director (Type 904 radar) is at the center of the photograph; and a Dutch M40-series director is at the right. This equipment was on board British and Dutch *Leander*-class frigates lying alongside at Portsmouth, 1979. The big radar at the left is Type 965, and that at right is the Dutch LW-02, which the Royal Navy considered buying instead of 965. (Author)

controlling the missile. GWS 21 uses the Type 262 close-range radar; it is equivalent to MRS 8. The director is an open-topped cylinder carrying an aimer and a director officer, and there is a secondary optical sight. GWS 21 was an interim development pending availability of GWS 22, the full blind-fire director.

GWS 22 is an adapted MRS 3, with a Type 904 radar. The enclosed director-officer's blast hood of MRS 3 is replaced by an open platform carrying binoculars, and there is no director-aimer's position; the sole occupant of the director slews it into tracking position. GWS 22 entered service in 1962.

◆ MRS 3

This medium-caliber fire-control system was adapted from the U.S. Mk 56. The standard postwar British medium-gun control system, MRS 3 is distinguishable by the projection rising from its roof, the director-officer's blast hood. The window on the front of the director indicates the director-aimer's position, with the Type 903 antenna alongside.

MRS 3 was conceived as a version of the U.S. Mk 61 director, but when that was canceled the project was recast as a British version of the larger and more complex Mk 56. It was Anglicized, using standard British components, and thus was not a direct copy. When the full range of British fire-control systems was reviewed in 1949, the long-range type (LRS 1) was canceled; and it was decided that, since MRS 3 was the only surviving type with a useful blind-fire capability, it would be expanded at the expense of other prospective long- and medium-range systems. The development effort was cut by substituting an electro-mechanical predictor (like the one developed for Flyplane) for the U.S. mechanical linkage. This choice carried a space and weight penalty, but it also made for easier changes in ballistics. This predictor still used the same basic formulae as Mk 56, and its empirical solution was most effective between 3000 and 5000 yd. The result was a 2-operator director with a 903 radar, an electro-mechanical predictor and plane converter, and a gun data unit for separation corrections (corrections due to the difference in location between gun and director) and outgoing transmissions. Maximum range error was 500 yd, and maximum angular error 6 deg in spiral-search mode.

There were several modifications. The addition of Fire Control Box Mk 10, for better surface fire, resulted in the AA/SU 1 system. For blind-fire, GRU Stabilizer Mk 3 was added (AA/SU 2). A splash-spotting radar, Type 932, could be added for

MRS 3 director, HMS *Diamond*, resembles the U.S. Mk 56. The radar is Type 903. (A. Raven)

improved spotting in surface fire (this was AA/SU 3, in the *Tiger*-class cruisers, now extinct).

The first contract was awarded to Sperry in 1947, and work on MRS 3 (as a Mk 56 derivative) began in 1948. The director entered service in 1958, and work on the related GWS 22 began in 1959. In all, over 120 MRS 3/GWS 22 were manufactured, for 8 navies. An MRS 3 update program (Mod 3) began in 1962. Finally, 60 MRS 3 were updated with solid-state electronics in 1974–78.

Of other systems in the MRS series, MRS 6 was a cruiser secondary battery control system using the Mk 6 director, with radar Type 275; it is now extinct. MRS 7 was another system using the Mk 6 director, but to control 4.5-in rather than 4-in guns, i.e., for destroyers (modernized *Battle* class). It, too, is now extinct. Both systems used electric computers (SEDC, the Simple Electric Deflection Calculator). MRS 7 also incorporated a range-control fuze unit and firing-control unit, an electric cross-level calculator and cross-level-angle calculator, and a tangent elevation unit. The main weaknesses of the original Mk 6 had been poor deflection computing by the old fuze-keeping clock, the absence of an automatic fuze predictor and transmitter (which made for excessive dead time), limitations of the cross-level stabilizer, and the excessive number of hand follow-ups (which were slow and could be inaccurate).

The SEDC used a simple solution, which was not always accurate because some constants were used to replace variables. Two sets of constants were provided, for target speeds of 110–150 kt ("practice values") and 250–450 kt ("operational values").

The automatic fuze transmitter replaced a hand follow-up used in earlier directors to transmit future ranges (i.e., fuze time delays) calculated by the fuze-keeping clock. In the earlier system the fuze number still had to be called out to the fuze transmitter, who transmitted manually to the gun. The result was excessive time lag and error. The replacement was a Range Control Fuze Unit (RFCU). Typical RFCU parameters would be target speed 450 kt, future range 3500 yd, and dead time 4 sec.

◆ MRS 8

This short-range anti-aircraft fire-control system uses the Type 262 radar and evolved from the earlier CRBFD (close-range blind-fire director). MRS 8 could control 40-mm, 4-in, or 4.5-in guns. MRS 8 was essentially a CRBFD with its predictor replaced by a below-decks computer (single or dual ballistic unit, depending on which guns were being controlled). The dual ballistic unit also automatically opened fire when a target came within effective range.

As these directors became obsolete, they were converted into GWS 21s for Sea Cat control.

◆ Sea Archer 1 (GSA 7)

Sea Archer is the Sperry (UK) manned optronic weapons-control system. Sea Archer 1A adds below-decks controls. Sea Archer uses a modified Laurence Scott optical fire director (OFD). Applications include the Omani landing ship *Al Munassir*. As GSA 7, Sea Archer 1 controls the 76-mm gun of the British *Peacock*-class patrol vessels. A GEC V3800 thermal imager was added to their GSA 7s in 1986.

As supplied to the Royal Thai Navy in 1986, Sea Archer 1A had an LLLTV (dual 12/3 deg FOV), a GEC V3807 thermal imager (LST version only), and a laser range-finder.

A Sea Archer 1B version, announced in 1983, has an unmanned director and autotrack.

The director is line-of-sight stabilized. The associated predictor turns the director into the direction of the target; the operator searches only in elevation to acquire the target. The operator tracks it by using a joystick with a pistol grip that contains controls for slew, for doubling the director rate. There is also a rate memory. Once the target has been acquired, the operator releases the director from predictor control and triggers

the range-finder. The latter may be either a range-only radar or a laser. Because the laser has so narrow a beam, the operator needs an indication that the beam has in fact pointed at the target; when the laser finds the target, the operator is given an audible click in the earphone. The operator's binoculars can be replaced by a trillite image intensifier or by an LLLTV. It is also possible to replace the binoculars with a day/night scope, which allows the operator to view a scene either in natural light or in IR.

Sea Archer development began in 1974; Sea Archer 1 was ordered by the Royal Brunei and Omani navies in 1976. Sea Archer 1A Mod 0 was ordered for Oman and for the Royal Navy (as GSA 7) in 1980. Mods 1 and 2 were ordered for the Royal Thai Navy in 1985–89.

◆ Sea Archer 30

This optronic gunfire-control system was developed by Sperry (UK) and then taken over by British Aerospace. First displayed at RNEE 83, Sea Archer 30 was adopted in 1985 by the Royal Navy to control 4.5-in guns on board Type 22 and 23 frigates, under the designation GSA 8/GPEOD (Gun System Automation 8/General Purpose Electro-Optical Director). It is the first entirely autonomous digital Royal Navy gunfire-control system.

Sea Archer 30 was conceived as a follow-on to the original Sea Archer 1 and the abortive Sea Archer 2; it was initially to have been marketed as Sea Archer 3. The development of an autotracker and a remote optical director (1980) led to work on an entirely new system. In 1982 BAe developed a General-Purpose Electro-Optic Director (GPEOD), and Sea Archer (GSA 8) followed in 1985. An entirely new unit was needed because Sea Archer 1A was clearly at the end of its development potential; Sea Archer 30 uses a new single-board computer and a data bus. It can accept inputs from a tracking radar, tactical data system, or 1 or 2 bridge pedestal sights. The fire-control system can be directed onto an urgent target by a special externally generated ALARM AA signal; the system can also be used for passive surveillance.

The above-decks director is spherical, both to reduce wind loading and to reduce radar cross section. It has a swept radius

Sea Archer 30. (British Aerospace)

Sea Archer 30s atop the bridge of the British frigate HMS *Cumberland*, with a Sea Wolf director between them. (G. Arra, 1989)

of 448 mm and weighs about 200 kg. The internal power unit weighs another 45 kg, the gun-control console 230 kg, and the predictor unit 110 kg. Elevation limits are $+75/-35$ deg; training and elevation rates are both 90 deg/sec. Designed MTBF is 175 hr.

The spherical director carries an IR camera, a laser range-finder, and a daylight television. The IR camera operates in the 8–12-micron band and has a zoom lens giving magnifications of 3.6–20 (corresponding FOVs are 16.7×11.1 deg and 3×2 deg). Resolution is 512 lines. The detector is a Stirling-cooled Mullard SPRITE. The Ne-YAG laser operates at a wavelength of 1.06 microns, with maximum peak power of 10 MW and maximum PRF of 12.5 Hz. Range accuracy is less than 4 m for ranges of less than 5000 m, and less than 5 m for longer ranges. The daylight television uses charge-coupled devices (CCDs) and has a zoom lens with resolution and FOV similar to those of the IR camera; horizontal FOV is continuously variable between 17 and 3 deg, with a 4×3 aspect ratio. It has a remotely operated focus control.

The 2 below-decks units are a predictor (ballistic computer) and a console with a joystick and firing switch. Data buses connect the electro-optic director to the console (desk unit), and the console and predictor are connected by data bus. The predictor is itself connected to the guns and to the target-designation sight. The predictor has 2 filtering and prediction channels so that it can control guns of up to 2 calibers. The

prediction programs are held in read-only nonvolatile memory and, thus, can survive power failure.

There are 3 automatic tracking modes: edge, centroid, and correlation. Centroid is automatically selected for air targets and correlation for surface (i.e., for targets in strong clutter), but the operator can override these choices. The tracking gate around the target automatically adapts to target size and shape, to avoid confusion with decoys such as flares. The point of aim can be moved manually while the system is autotracking, e.g., while tracking a crossing air target. In the correlation tracking mode, the system automatically coasts at the last known target angular rate if track is lost, e.g., if the target disappears behind clutter. The optional auto-acquisition feature marks and tracks detected targetlike objects within the sensor's FOV.

The Royal Navy initially expected to order 2 separate systems, 1 for gunfire control (GSA 8) and the other for electro-optic surveillance. The GSA 8 specification demanded 4 director functions: naval gunfire support, antiship engagement, anti-aircraft engagement, and chaff shell firing for both distraction and wind-finding. The BAe system competed against 1 based on the Ferranti WSA 500 Modular Combat System.

BAe proposed that the 2 requirements be merged, using common modules from the UK Common Module Thermal Imager program. The resulting system has a very large (240-mm) object lens (with a 3-deg FOV at maximum zoom) and a 20-power telescope, and the manufacturer claims that it can detect targets beyond 20-km range. At 10 km, IR resolution is less than 1 m.

In the British competition, BAe won primarily because of the quality of the EO director, and particularly its stability and resilience to vibration. The Royal Navy also imposed very stiff

The DES Target Designation Sight, on display at RNEE 1989. The bulbous object is a handhold (the target side of the designator is visible). (DES)

weight, size, and power constraints. The Royal Navy ordered Sea Archer 30 in 1985. It is fitted to Type 22 Block III frigates (1 on each side) and to Type 23 frigates (1 per ship); as of October 1989, 20 were on order for the Royal Navy. BAe has developed the necessary software for 76-mm, 57-mm, 40-mm, and 30-mm gunfire control, in addition to the basic Royal Navy 4.5-in requirement.

The Royal Navy did not want automatic target acquisition, but the Sea Archer system can accommodate such a system, and it was tested in the U.S. trials mentioned below. Further planned improvements include an anamorphic lens for greater range.

BAe offers Sea Archer both as a full-up EO/GFCS system and also as a pure IRST, the latter in competition with equipment such as the Canadian SAR-8.

With the failure of the U.S. Seafire program, BAe proposed Sea Archer as an interim substitute. It does lack some of the features of the U.S. system, particularly the long-range laser-designation capability (stability and beamwidth) required to control laser-guided 5-in shells at maximum range; but Sea Archer is much lighter, and it does provide a valuable IR surveillance capability.

Sea Archer 30 was tested at NSWC Dahlgren between mid-September and mid-December 1988, under the Foreign Weapons Evaluation program. The targets were A-4, A-7, and F/A-18 airplanes, helicopters, surface craft, and moving shore targets. In a typical run, an A-7 flying at 1000 ft was first seen at 32,300 yd and acquired at 23,000 yd. Image processing was very important for such performance. For example, images could be edge-enhanced to make them stand out at long range.

Late in 1990 McDonnell Douglas Helicopters and GEC Sensors proposed an alternative optronic system based on the U.S. mast-mounted sight (see the U.S. section) and the GEC search/track system. Reportedly, the proposal was made after production problems were encountered with Sea Archer 30s for new Type 23 ("Duke"-class) frigates.

◆ Sapphire

The Marconi/Sperry (U.K.) Sapphire radar fire-control system employs a Marconi ST802 or ST1802 radar, the predictor (the Sperry Digital Weapon Controller [DWC 100], consisting of a Sperry 1412 Computer and its interface and power supply) developed for the Sea Archer system, and a 1-operator control console. The system can function against air targets (in direct or coasting mode), against surface targets at relative speeds of up to 60 kt, and for naval gunfire support (including fuze computation for starshell and chaff). The AA coasting mode is extrapolation of target motion in the event that a target fades, e.g., passes behind terrain or chaff. Normally engaging targets designated from a search radar, Sapphire can also search autonomously, particularly against low-flying targets. In the horizon-search mode, a 0.1 m² sea-skimming missile can be detected at 12–15 km.

Typical system reaction time, including slewing to a designated target, is 7 sec. The ST802 radar director accommodates a television camera, which automatically becomes the main tracker if the target drops below an elevation angle of 1.5 deg, to eliminate multipath effects. Full radar tracking resumes automatically when the target passes above this angle. In a mass stream attack, the television can be used to acquire a second target while the first is being engaged, the radar being used to track the target being engaged.

The associated Sperry 1412A computer has a capacity of 16 kwords. It recalculates gun orders 64 times per second and provides new output 512 times per second.

Sapphire was evaluated for the Royal Navy in 1975 and announced in 1976 (and first sold that year); and an improved version was announced in 1985 (using the ST1802). The first Sapphire entered service about 1979. As of 1989, sales were: single systems in each of 6 Egyptian 6 *October*-class fast attack boats and 6 *Ramadan* class and 2 Kenyan *Nyayo* class.

UNITED STATES

RADARS

◆ BPS-5/12/14

Band: X **Beam:** 2.6 × 16 deg **Peak Power:** 75–110 kW
Gain: 29 dB **Pulse Width:** 0.5 microsec
PRF: 600 pps **Scan Rate:** 0–8 rpm
Antenna Dimensions: 3 × 0.75 ft
Antenna Weight: 300 lb (total weight 2050 lb)

Data apply to BPS-5.

Lockheed Electronics's submarine surface-search radar was originally designed for special target submarines (SSTs) but later installed on board *Permit*-class attack submarines. Reliable range on a destroyer was 12 nm, and accuracy up to 60,000 yd was 25 yd ± 0.1% (to 120,000 yd, accuracy was 2% of range). Bearing accuracy was 0.25 deg. Range limits: 200 and 160,000 yd.

BPS-12 is a redesigned version, by Fairchild Camera and Instrument, using both a periscope antenna and a conventional one. Peak power is 75 kW and range limits are 400 and 80,000 yd. BPS-14 is very similar, except that its antenna drive is designed for use from within the submarine.

◆ BPS-9

Band: X **Beam:** 2.6 × 16 deg **Peak Power:** 75–110 kW
Gain: 36 dB **Pulse Width:** 0.5 microsec **PRF:** 600 pps
Scan Rate: 0–8 rpm **Antenna Dimensions:** aperture 16 ft
Antenna Weight: total installation weight 4000 lb

This submarine surface-search radar is a modernized equivalent of the early postwar SS-2. BPS-9 was developed by Western Electric and first delivered in December 1958 (for SSBNs).

BPS-9A has a retractable antenna.

◆ BPS-11

Band: X **Beam:** (i) 2.6 × 16 deg (ii) 30 × 10 deg
Peak Power: 75–100 kW **Gain:** (i) 29 dB
Pulse Width: 0.5 microsec **PRF:** 600 pps
Antenna Dimensions: (i) parabolic (ii) periscope antenna

BPS-11 is a redesigned BPS-1/4 for the SSBN 616 class, similar to BPS-5 except for the antenna. BPS-11 uses a horn (parabolic in BPS-11A). Range limits are 200 and 160,000 yd.

◆ BPS-15/16

Band: X **Beam:** 3 × 13 deg **Peak Power:** 35 kW **Gain:** 29 dB
Pulse Width: (i) 0.1 (ii) 0.5 microsec **PRF:** (i) 1500 (ii) 750 pps
Scan Rate: up to 9.5 rpm **Antenna Dimensions:** aperture 40 in
Antenna Weight: 168 lb

Sperry's surface-search/navigational radar uses a horn-array antenna. Minimum range is 25 yd, and range resolution is 30 yd in the short-pulse and 100 yd in the long-pulse modes.

BPS-15 radar, USS *Hawkbill*. (Ships of the World)

BPS-16 is the successor to BPS-15. Radar performance will be very similar, the main improvement being in the mechanical reliability of the mast. The 2 bidders were Norden and Sperry Marine, Norden being awarded the contract for what was then called BPS-() on 29 April 1987. The contract called for the development and production of 36 modular submarine radars. Sperry protested, and the contract was recompeted. Sperry ultimately received the contract, the radar now being designated BPS-16. First deliveries were due in 1990.

◆ SPS-5

Band: Xb (6400 MHz); C (5450–5825 MHz) in SPS-5C and -5D
Beam: 1.75×15 deg (csc² to 22 deg) **Peak Power:** 350 kW
Gain: 29 dB **Pulse Width:** 0.5 microsec
PRF: 680 pps **Scan Rate:** 17 rpm
Antenna Dimensions: 101×52.5 (including pedestal) $\times 101$ (depth) in
Antenna Weight: 205 lb including pedestal

Raytheon's small-ship surface-search radar was first delivered in 1952. Data above are for SPS-5C, introduced about 1960, which shifted from Xb- to C-band and used the AS-1002 antenna. Earlier versions used the AS-511 and -651 antennas.

USS *Bronstein* shows an SPS-5C surface-search radar, above her SPS-40 air-search set. Comparison with ships carrying SPS-10 will show how much smaller the -5C's antenna is. (U.S. Navy)

◆ SPS-6

Band: L (1250–1350 MHz) **Beam:** 3.5×30 deg
Peak Power: 500 kW **Gain:** 27 dB
Pulse Width: (i) 4 microsec (ii) 1 microsec
PRF: (i) 150 (ii) 600 pps **Scan Rate:** 2.5–15 rpm
Antenna Dimensions: $204 \times 95 \frac{7}{8}$ in
Antenna Weight: 924 lb (including pedestal)

SPS-6 was the first of the postwar generation of L-band air-search radars. These data apply to the SPS-6C version commonly installed on board destroyers and frigates. This radar could detect large high-altitude aircraft at 70–140 nm and fighters at 60–80 nm. SPS-6D omitted the integral IFF of SPS-6C, and -6E had a better receiver. Some sets may have had a peak power of 750 kW. The antenna was deliberately designed with a beam broad in its vertical dimension so that the radar could reliably detect high-altitude jets.

In U.S. service, SPS-6 remains on board only the *Thomaston*-class amphibious ships, but it is also in service on board destroyers, frigates, and similar vessels in foreign navies.

Although SPS-6 is virtually extinct in the U.S. Navy, many survive abroad. This photograph was taken in 1950, but current installations use the same antenna, typically at the masthead. (U.S. Navy)

◆ SPS-10

Band: C (5450–5825 MHz) **Beam:** 1.5×16 deg
Peak Power: 500 kW **Gain:** 30 dB
Pulse Width: (i) 0.25 (ii) 1.3 microsec
PRF: 625–650 pps **Scan Rate:** 15 rpm
Antenna Dimensions: $126 \text{ in} \times 76 \text{ in}$ (with pedestal)
Antenna Weight: 442 lb including pedestal

Data are for SPS-10B (AS-936 antenna).

SPS-10 was the standard U.S. surface-search radar; it has been superseded, to a limited extent, by SPS-55 and is being replaced

USS *Whipple* has an SPS-10 surface-search radar and an SPS-40. The tall antenna above the SPS-10 is her LAMPS data link. (U.S. Navy)

by SPS-67. In 1976 SPS-10 was considered the most reliable U.S. surface-search radar, with an MTBF of 150 hr (but with 5–6 hr MTTR because of the absence of automatic fault-finding equipment). The latest version is SPS-10G.

SPS-10 had a 285-kW transmitter; -10B introduced the current 500-kW type. SPS-10E introduced a new antenna (1.9 × 16-deg beam, 17 rpm), and -10F a new PRF (625–660 pps). The 2 pulse widths make for resolutions of, respectively, 41 and 213 yd. During trials in 1956 SPS-10 showed that it could detect a continuously exposed snorkel in sea-state 2 at an average of 9630 yd (maximum reliable range 12,100 yd) and could track a periscope (with 6 ft exposed) in sea-state 1 at 16,000 yd. Maximum reliable tracking range on a 3-ft attack periscope in sea-state 1 was 10,100 yd. These trials showed that the radar could reliably detect a submarine attack periscope intermittently exposed during an attack in sea-state 2 and below.

The associated IFF is integrated with the basic radar, and the IFF beam is 6 × 22 deg.

Some versions of this radar used the AS-1161 lightweight antenna, identical with the AS-1002 of SPS-5C. SPS-10 and -10A used AS-615; later versions use AS-936, which is essentially the same antenna with a 440-volt 3-phase drive instead of the earlier 110-volt single-phase drive. AS-936B adds an extension to the bottom of the antenna and "blinders" on the sides of the feed horn, to reduce sidelobes and minor interference with other ship antennas.

Deliveries began in October 1953. See also SPS-58, which sometimes uses the same antenna, and SPS-67.

◆ SPS-12

Band: L (1250–1350 MHz) **Beam:** 30 × 3 deg
Peak Power: 500 kW **Gain:** 25 dB

SPS-12 and SPS-10 radars on the foremast of the Canadian destroyer *Fraser*, 1989. (G. Till)

Pulse Width: (i) 4 microsec (ii) 1 microsec
PRF: (i) 300 (ii) 600 pps **Scan Rate:** 2.5–15 rpm
Antenna Dimensions: 205 × 92 in
Antenna Weight: 990 lb (with pedestal)

SPS-12 was, in effect, an improved SPS-6. Total weight was about 4600 lb compared to 2550 lb for SPS-6B. Although peak power did not increase, long pulses could be emitted at a higher rate, for twice the average power of the earlier radar.

SPS-12 was first delivered in September 1953. This radar was also manufactured under license in Italy. The Canadian SPS-501 consists of a Dutch LW-03 antenna combined with an SPS-12 transmitter. The last U.S. set was removed from the training carrier *Lexington* in 1984.

◆ SPS-29/37

Band: P (215–225 MHz) **Beam:** 19 × 25.5 deg
Peak Power: 750 kW **Gain:** 18 dB **Pulse Width:** 10 microsec
PRF: 300 pps **Scan Rate:** 7.5 or 15 rpm
Antenna Dimensions: 210 × 102 in (140 with pedestal)
Antenna Weight: 1275 lb including pedestal (below-decks weight is 8700 lb)

Although extinct in the U.S. Navy, this P-band radar survives in some foreign ships. The mattress antenna, AS-943, consists of 28 folded dipoles spaced a half wavelength apart vertically and horizontally, and about a quarter wavelength in front of a flat reflector.

This radar was first delivered in 1958; in all, 89 were made.

A few ships had SPS-28, whose antenna was virtually indistinguishable from that of SPS-29. SPS-28 operated in the same frequency band, but peak power was only 300 kW, pulse length 4 microsec, and PRF 120 pps; gross weight was 4440 lb, compared to 7510 for the much more powerful SPS-29. The antenna was AS-839.

A few U.S. destroyers had SPS-37, externally indistinguishable from SPS-29; some of these sets may also be in foreign service. SPS-37 is a pulse-compression radar with a peak power of 180 kW; pulse width is 200 microsec (compressed to 6), and PRF is 230–250 pps. The improved version, SPS-43, is now extinct. See the previous edition of this book for details.

SPS-29 antenna, USS *Intrepid*. (A. Raven)

◆ SPS-39/42/52

Band: S (2910–3100.5 MHz)
Beam: 1.1×2.25 deg. (1.9×2.25 deg in SPA-64)
Peak Power: 1000 kW **Gain:** 39.5 dB (37 dB in SPA-64)
Pulse Width: (i) 2.5 (ii) 4.6 (iii) 10 microsec
PRF: (i) 1850 (ii) 925 (iii) (see notes below) pps
Scan Rate: (i) 15 (ii) 6 (iii) 6 rpm (SPS-39A: 5, 7.5, or 15 rpm)
Antenna Dimensions: 165×167 in (including pedestal) (SPA-64: 165×160 in including pedestal)
Antenna Weight: 3200 lb (including pedestal) (SPA-64: 2950 lb)

These 3D radars are scanned electronically (frequency scanned) in elevation and mechanically in bearing. SPS-39 originally had a cylindrical-section antenna, but all ships now have the planar array, with a serpentine delay line on 1 side. Stabilization is achieved electronically. The antenna itself consists of a stack of 60 linear arrays. The early planar-array antenna (SPA-64) used 63 radiating slots per array; the later SPA-72 (for which most of the data above are given) uses 98. In each case, the antenna is tilted back at 25 deg, and total vertical coverage is 42 deg (41.6 deg for SPS-52B).

These radars use klystron transmitters. All have low-power modes (peak power 16 kW; but 14.4 kW, with 900 kW maximum, in SPS-52B) and variable pulse rates. SPS-39 and -39A have only 2-microsec (PRF 1850 pps) and 4-microsec (PRF 925 pps) pulse widths. SPS-39A's PRF is 488–2000 pps. In the order given above, SPS-52A's PRFs are 1220–2000, 488–2000, and 329–1050 pps. Presumably, the figures above are the usual values corresponding to the given pulse widths. Below-decks weights: SPS-52, 15,500; SPS-52B, 15,934 lb; SPS-52C, 14,040 lb.

The original SPS-39 was credited with a maximum range of 160 nm and a maximum altitude of 75,000 ft. The pulse data above refer to an improved (Series III) version introduced in 1963, with the planar-array antenna. The 3 modes were high-data-rate mode (i), with an instrumented range of 60 nm; high-angle mode (ii), 160 nm; and long-range mode (iii), 245 nm. Maximum elevation in the high-data-rate and high-angle modes was 42 deg (with an alternative limited angle of 13 deg in these

modes and in the normal long-range modes), and there was an alternative limited long-range mode with a 4.5-deg maximum elevation. The improved SPS-52 is credited with a maximum range of 240 nm and a maximum altitude of 100,000 ft (maximum elevation 42 deg).

SPS-42 was an SPS-39 modified to provide data directly to NTDS.

SPS-52 introduced the planar-array antenna now standard for both types, as well as a parametric amplifier and a wide-pulse feature for longer range. Stabilization is digital rather than analog. The computer was originally the Hughes H3118, but SPS-52B is generally credited with a standard navy UYK-15. SPS-52B introduced clutter rejection.

The current SPS-52C employs a UYK-20 computer. It is responsible for stabilization and beam control, target processing, and the interface with SYS-1. For ATD, a video extractor and control group (VECG) were added for radar-beam-control conversion functions, as well as a radar video converter (RVC) for SYS-1. The VECG can store up to 9 consecutive detections of the same object, find their centroid in 3 dimensions, and then pass that centroid's location to the IADT as a single target report, thus reducing the IADT's workload and increasing the overall system's accuracy. SPS-52C is also more reliable than its predecessor, with an MTBF (as reported in 1979) of 216 hr, compared to a requirement for 170 hr: a 14% improvement over SPS-52B.

SPS-52C has 4 modes: high-angle (moderate range and data rate); long-range (high-energy pulse); high-data-rate (quick detection and rapid update of close-in targets); and MTI (clutter rejection). For medium range, the radar has a 6-sec data rate (scan at 10 rpm); for long range and MTI, 8 sec (7.5 rpm); and for short range, 4 sec (15 rpm).

SPS-39 was first delivered in January 1960; it was the first operational U.S. frequency-scanning 3D radar. -39 suffered from limited reliability (in 1960–62 MTBF was only 14.3 hr, although figures as great as 67.4 hr were achieved on board some ships). SPS-52's development began about 1963.

SPS-52C's design began in 1973, and it (with SYS-1) was tested on board USS *Towers* beginning in December 1977; approval for service use was granted in 1978.

For details of the associated IFF antennas, see the entry for SPS-48 below.

SPS-52C was planned for installation on board all surviving U.S. ships equipped with the earlier SPS-39/52 (the frigates have SPS-52 or -52B; the destroyers may have retained SPS-39 or -39A). However, in August 1981 it was deleted from the planned modernizations of the *Brooke* and *Adams* classes (except for the 3 heavily upgraded *Adams*-class destroyers). It has been installed abroad, on board Australian and German *Adams*-class missile destroyers. The French *du Chayla* retains her SPS-39, as do the Italian *Caio Duilio*s and *Impavido*s. The Italian *Vittorio Veneto* apparently has SPS-52B, but the *Audace*- and *Animoso*-class missile destroyers appear to have SPS-52C. The Japanese *Hatakaze* class have SPS-52C, but the older missile destroyers have SPS-52B, as do the Spanish *Baleares* class.

Foreign navies did not always buy the same package, including the same computer, as the U.S. Navy. The Spanish SPS-52B (on board the *Baleares* class) is midway between a U.S. SPS-52B and -52C, with a Spanish-developed radar-integration system. The Japanese SPS-52C has special features. It also uses a new antenna, physically indistinguishable from its predecessors, but with its elements embedded in plastic (like the parts of a surfboard) rather than covered by a thin plastic sheet.

SPS-52C production ended in 1989, but several navies (including those of Australia and Canada) have since shown interest in purchasing it, and Hughes may yet license foreign production of a solid-state version, e.g., for modernization of the *Brooke*-class missile frigates and *Adams*-class destroyers now being transferred to foreign navies. Hughes decided to cease production because its improved version of TAS Mk 23 enjoyed much the same range performance as SPS-52, but with a much better data rate; it saw ITAS as the natural successor to SPS-52.

An SPS-52C antenna, on board USS *Tattnall* (DDG 19), the first ship so fitted. The bar above is an IFF interrogator. (Hughes)

◆ SPS-40

Band UHF: (400–450 MHz band) (10 channels)
Beam: 11×19 deg **Peak Power:** 200 kW (pulse compressed)
Gain: 21 dB **Pulse Width:** 60 microsec (compressed to 1.0)
PRF: 300 pps (jittered)
Scan Rate: 7.5 or 15 rpm (6 rpm in SPS-40 and -40A)
Antenna Dimensions: $216.0 \times 116.8 \times 111.0$ (deep) in
Antenna Weight: 1425 lb, including pedestal (1728 lb for SPS-40B and later versions) (3200 lb below decks; 3400 lb for SPS-40A; 3474 lb for later versions)

This radar and SPS-49 are the current standard U.S. 2D sets. SPS-40 is in effect a compromise between very long range (achieved by using low frequency) and reasonable definition; 400 MHz is about the minimum acceptable frequency for a current set, because the next lower band, around 200 MHz, cannot provide enough information.

The original SPS-40 was manufactured by Lockheed Electronics. SPS-40A, an improved version by Sperry, introduced a broad-band transmitter and some solid-state receiver changes. Peak power was increased to 255 kW. SPS-40B, by Norden, incorporated a new IFF (AIMS), for air control of friendly aircraft, a low-flyer-detection mode (LFDM), digital MTI (DMTI), and an automatic target detector (ATD) that allows the radar to feed into an automatic combat system (SYS series). DMTI provides clutter rejection over land. ATD employs a radar-video converter (RVC), which automatically detects targets and provides range and bearing data to the central combat-system computer. There are also ECCM improvements. SPS-40B and later versions have an alternative 3-microsec (short) pulse and alternative PRFs of 278 and 300. SPS-40C is a modified SPS-40A (to -40B standards), incorporating LFDM and reliability improvements. SPS-40D is a modified SPS-40A corresponding to SPS-40C standards. An improved antenna is under development, and Norden has developed a frequency-agility (FA) module. It selects an unjammed frequency and shifts frequency on a pulse-to-pulse basis. Other possible improvements are main and sidelobe cancelers; at present the antenna has fairly fat sidelobes (27 dB horizontal, 10 dB vertical).

Data above apply to SPS-40B; some models may compress the 60-microsec pulse to 0.6 microsec. Minimum range is 0.25 nm. Current MTBF is 252 hr; MTTR is 45 min. The transmitter is a tetrode tube.

The latest version, SPS-40E, incorporates a new Westinghouse solid-state transmitter (SSTx), intended for 90% probability of maintenance-free operation for 90 days, with no more than 11% reduction in range performance. The SSTx can also power up very fast so that the ship can operate with her radar shut down when in EMCON without risking loss of radar capability when it is needed. In addition, the SSTx automatically protects itself from damage due to battle damage to the waveguide or antenna; it shuts down, then powers up to the level allowed by the other components. Westinghouse offers a less expensive, lightweight (half power) SSTx for coastal defense.

◆ SPS-48

Band: S (2900–3100 MHz) **Beam:** 1.5×1.6 deg
Peak Power: 2200 kW **Gain:** 38.5 dB
Pulse Width: 3 microsec (per beam: 27 total)
PRF: 1250–2000 pps **Scan Rate:** 7.5 or 15 rpm
Antenna Dimensions: 194×228 in (including pedestal)
Antenna Weight: 4495 lb (including pedestal) (below-deck weights: -48, 18,211 lb; -48A, 19,651 lb; -48C, 20,548 lb) SPS-48E: 5684 lb above-decks (24,018 lb below-decks).

SPS-48 is the most sophisticated U.S. frequency-scanning radar, scanning multiple beams in elevation to combine long range with high data rate and multiple-pulse (i.e., high-probability) detection. Each stream of 9 pulses generates 9 beams, spread in frequency to give a total spread of 6 deg for the group. Successive groups elevate from 0 to 45 deg. In an alternative burn-through (antijam) mode, the entire 27 microsec are transmitted at 1 elevation angle, and pulse-compressed (with a ratio of 9:1). There is also a 9-microsec pulse. Instrumented range is 230 nm, and rated range is 220 nm, with a minimum ceiling of 100,000 ft. Vertical coverage is up to 45 deg. The transmitter is an amplatron.

SPS-48C incorporates ADT.

SPS-48E (formerly SPS-48NTU), the current version, doubles the effective radiated power, reduces sidelobes (sidelobe level is -33 dB, compared to -23 dB for earlier versions of this radar), and increases the receiver's sensitivity. Maximum elevation angle is increased to 65 deg. Because the antenna incorporates ferrite phase-shifters, SPS-48E can combine pulse compression (i.e., frequency-swept pulses) with vertical phase scanning in frequency. The ferrites are interposed between the serpentine feed and the slotted arrays, compensating for the frequency sweep within each pulse. Pulse width is 27 microsec (compressed to 3 microsec). Input power: -48, 65.8 kVA; -48A, 72 kVA; -48C, 74 kVA; -48E, 112 kVA.

Associated with the New Threat Upgrade (NTU: SYS-2) program, SPS-48E incorporates a new cross-field amplatron trans-

SPS-40, with SPS-10 below it. (W. Donko, 1987)

SPS-48 on board the USS Enterprise, 1990. (A. Chiffolo)

mitter with twice the average output and greater reliability (it can continue to function despite some subcomponent failures, a technique called fail-soft), a digital receiver/frequency control, and a combined programmer/processor with half the equipment racks of previous versions. There is also a new single unified display group. The new transmitter permits snap-on/snap-off operation for simpler and more complete EMCON. All of these improvements have greatly increased the system's reliability. Predicted MTBF was 268 hr; but in a 146-day Sixth Fleet deployment, SPS-48E achieved an MTBF of 586 hr. The first ship to be fitted was USS *Biddle*.

Improved reliability is, in part, a result of a redesign that reduced radar part count by over 50% (280,000 to 126,000). The number of required adjustments has been reduced from 768 to 70, and the operator typically chooses among only 4 scan modes, with adjustments of 4 controls.

SPS-48E has 3 transmitter power modes (high, medium, and low power). Energy coverage modes are: equal angle coverage (EAC), maximum energy management (MEM), and adaptive energy management (AEM). In EAC mode, the highest power is concentrated at the lowest elevation angle, so that detection range is greatest at the elevation angle at which most targets are likely to appear. Cover is provided from the horizon to 45-deg elevation, and out to 220 nm (instrumented range). MEM provides high power in the lowest 4 elevation groups and medium power in the upper 4. AEM is automatically activated when SYS-2 generates a priority track gate or surveillance priority gate around a target or expected target area of particular interest. The radar adapts its power to the jamming environment and target's cross section. There are both 5-deg (in elevation) and 2-deg (chirp) modes. Both of these modes can be steered, whereas the other modes merely involve the preset elevation channels. The beam can also be scrambled to complicate countermeasures.

SPS-48D was the engineering development prototype for -48E and was tested on board USS *Mahan* in 1982-83, including operations off Lebanon.

Data refer to the AS-1686 antenna. The antenna, electronically stabilized against pitch and roll up to 20 deg, consists of 76 linear horizontal arrays. The new SPS-48E antenna has 95 linear arrays, each 18 ft long, with a total height of 18 ft.

SPS-48 is manufactured by ITT-Gilfillan.

Several IFF antennas can be used with SPS-48: AS-1065, AS-1688, AS-2188, and AS-3430. AS-1688 is intended as an integral part of the SPS-48 antenna; the others can be mounted either independently or on the antenna. Beamwidths: 9×45 deg for AS-1688, 7×48 deg for AS-2188, and 7.5×50 deg for AS-3430. These antennas are also used for other major U.S. radars.

In 1985 ITT-Gilfillan displayed a new GaAs/fiber-optic technology (then in its early stages) for a future phased- (active) array radar. In such a radar, the waveform is created, and phases are shifted and then transmitted via optical fiber into the bank of GaAs RF transmitters in the antenna. That scheme greatly reduces the usual power losses in such a radar; in a conventional radar, the phase shifters themselves cost 1.5-2 dB (and faster phase shifting consumes more power), not to mention the DC power required to run the diode phase shifters (typically tens of kW). In the fiber-optic radar, phase shifting is done at very low power. The other alternative, phase shifting by frequency scanning (as in SPS-48), is limited by microwave frequency. For widebeam steering, the antenna must use time-delay beam-forming; the beam must be many wavelengths across and very precisely made. By doing the beam-forming and beam-steering in the cabinet rather than in the antenna, the fiber-optic radar can use cut lengths of fiber and integrated optical switches to create the necessary time delays. In theory, then, an individual optical fiber would be used for each element; but wavelength multiplexing can give as many as 10 elements/fiber, so that the apparent requirement for about 6000 can be reduced to 600. The result should be less expensive high-resolution beam-forming with adaptive weighting for better beam-shaping.

SPS-48 was designed because SPS-39 had insufficient range for the Talos missile system; development began in 1959. The first production set went to sea on board the cruiser *Worden* in March 1965.

◆ SPS-49

Band: L (851-942 MHz) **Beam:** 3.3×9 deg

Peak Power: 280 kW

Pulse Width: 125 microsec, compressed (ratio 83:1); there is also a 2-microsec pulse for short ranges

PRF: 280 pps for long range, 800 or 1000 pps for short range

Gain: 29 dB **Scan Rate:** 6 or 12 rpm

Antenna Dimensions: 288×171 in (including pedestal)

Antenna Weight: 3040 lb (including pedestal)

SPS-49, manufactured by Raytheon, is the best current U.S. 2D air-search radar. It is currently replacing the SPS-37/43 series. Based on experience with the SPS-40, Westinghouse was (1988) conducting full-scale engineering development of a solid-state transmitter (SSTx) to replace the SPS-49's existing klystron (vacuum-tube) transmitter.

The radar is mechanically stabilized in line of sight and is adapted to ADT. Total below-decks weight is 13,791 lb.

Versions of SPS-49 are denoted by (V) numbers. (V)1 is the original version, e.g., on board *Perry*-class frigates. (V)2 was the version for New Threat Upgrade (NTU) modernization of cruisers. (V)3 is the Canadian version, with an embedded tracker (i.e., with ADT). (V)5 is the current ATD version, with a digital signal processor that requires its own cooling system. (V)7 is essentially the same radar without the cooling package, for ships such as *Aegis*, which provide cooling.

The (V)5 version employs digital pulse-doppler processing to reject clutter; the system has parallel coherent and incoherent processing channels, a mean-level digital CFAR processor, 5 finite-impulse-response (FIR) doppler filters, and amplitude clutter-map compensation in each channel. To reject jamming through the sidelobes, the system uses a 4-loop coherent sidelobe canceler (CSLC), and jammers' bearings are automatically detected and reported digitally. The PPI shows a jammer-direction-finder (JDF) strobe. There is a special antichaff mode, in which PRF is increased to improve doppler processing.

SPS-49 on board the USS *Fahrion*, 1984. (A. Raven)

The beam can be elevated (up-spotted) to help reject main-lobe jamming.

Peak power is increased to 360 kW (average power is 13 kW, compared to 10 kW for earlier versions described above), and the beam is $3.4 \text{ deg} \times 30 \text{ deg csc}^2$; antenna gain is 28.5 dB. Range accuracy is 0.03 nm, and bearing accuracy is 0.5 deg. Estimated MTBF is greater than 600 hr, and MTTR is less than half an hour. Total above-decks weight is 3165 lb, and below-decks weight is 14,004 lb; the power requirement is 86 kVA of 440 volt power and 10.1 kVA of 115 volt power. The internal space requirement is about 200 ft².

For details of IFF antennas, see the entry for SPS-48 above.

SPS-49 was conceived as part of the same frequency-diversity program that produced SPS-40; the prototype was tested on board the destroyer *Gyatt* between July 1964 and June 1965. Although this radar figured in many U.S. warship designs of the late 1960s, it was not bought in numbers. However, it was revived in 1970 in much modified form and then evaluated on board the missile cruiser *Dale* in 1976. SPS-49 was first bought in quantity to equip U.S. *Perry*-class missile frigates. As a measure of improvement in reliability since the mid-1960s, the original prototype showed an MTBF of about 60 hr, a tenth of the current figure.

Work is currently proceeding on an IADT (i.e., SYS-type system) for *Perry*-class frigates, to tie their air- and surface-search radar pictures together. Operational evaluation is scheduled for FY89.

Several major SPS-49 improvements are being considered, some under a Naval Research Laboratory program, SENRAD. One is an SSTx. The other may be an antenna upgrade, possibly a planar-array 3D antenna. The 2 goals would be reduced side-lobes and an agile beam. Any future agile-beam antenna would probably employ phase shifting for beam steering since the transmitter would have to employ pulse compression and would probably be frequency agile. Phase shifting might be done either at low power (before the signal passes through the amplifier) or at high power (in the antenna itself). Phase shifting at low power might be easier, but in that case the radar would have to pass multiple signals simultaneously through its rotary joint (otherwise the signals are multiplexed in the antenna, e.g., by stripping them from a serpentine waveguide that imposes phase differences). Westinghouse recently received contracts for both the SSTx and a 20-channel UHF rotary joint.

Westinghouse has been developing low-sidelobe UHF planar-array dipole antennas for some time. FASR (Fixed Array Surveillance Radar) is a $31 \times 12\frac{1}{2}$ -ft array consisting of 2 rows of vertical strip-line elements (27 per row). It was developed under contract for NRL. Another dipole array antenna was developed for the SPS-65 radar (see that entry).

As of 1989, the navy is also considering an improved SPS-49 processor, to take advantage of the new antenna. All of these projects are still in the experimental stage, but the French navy expects to replace its standard long-range 2D radar, DRBV 26, which is broadly analogous to SPS-49, with a long-range 3D

radar. That process would seem to meet the threat of high-altitude, steeply diving missiles such as AS-4/6, which may pass over the coverage of long-range 2D air-search radars.

Full-scale engineering development of the SPS-49 SSTx began under the FY88 program. The FY90 program includes development of signal-processing modifications and also of a phased-array antenna for SPS-49.

◆ SPS-53/60

Band: X **Beam:** (a) $1.6 \times 20 \text{ deg}$ (b) $1 \times 20 \text{ deg}$
Peak Power: 40 kW **Gain:** 30 dB average
Pulse Width: (i) 0.5 (ii) 0.1 microsec
PRF: (i) 750 (ii) 1500 pps **Scan Rate:** 15 rpm
Antenna Dimensions: (a) 5 ft (b) 8 ft
 AS-1652: $59 \frac{7}{8} \times 22 \frac{3}{8} \text{ in}$
 AS-2321: $59 \frac{7}{8} \times 21 \frac{1}{4} \text{ in}$
 AS-2322: $96 \frac{1}{4} \times 21 \frac{1}{4} \text{ in}$
 AS-2645: $96 \times 22 \frac{3}{8} \text{ in}$
Antenna Weight: (includes pedestal)
 AS-1652: 100 lb
 AS-2321: 87 lb
 AS-2322: 97 lb
 AS-2645: 100 lb

Sperry's high-resolution navigational radar is used by both the coast guard and the navy. The antenna is a slotted waveguide. In some ships it replaced SPS-5. Minimum range is 25 yd; maximum range is 32 nm. The current version is SPS-53M. Four antennas, all slotted waveguides, are used, two 5-foot and two 8-foot. AS-1652 (5 ft) is used with SPS-53, -53A, B, and H; AS-2321 (5 ft) with -53D, F, G, K, and M; AS-2322 (8 ft) with -53E and L; and AS-2645 (8 ft) with SPS-53J.

SPS-60 is a solid-state version of the vacuum-tube SPS-53E and uses a standardized 8-ft navy antenna. SPS-60 survives in U.S. service on board minesweepers and auxiliaries.

◆ SPS-55

Band: X (9.05–10.00 GHz) **Beam:** $1.5 \times 20 \text{ deg}$
Peak Power: 130 kW **Gain:** 31 dB
Pulse Width: (i) 0.12 (ii) 1.0 microsec
PRF: (i) 2250 (ii) 750 pps **Scan Rate:** 16 rpm
Antenna Dimensions: $80 \times 28 \text{ in}$ (including pedestal)
Antenna Weight: 195 lb including pedestal

SPS-55 is the X-band successor to the C-band SPS-10; the frequency was chosen to avoid interference with C-band missile trackers. The antenna consists of 2 slotted waveguides arranged back to back, the operator choosing either circular or horizontal polarization. The former helped to overcome rain clutter, as the rain drops tend to reverse the circular polarization of the waves they reflect, and the radar can reject signals of opposite polarization. More complex targets do not reverse polarization in so systematic a way; and their echoes are, therefore, not entirely rejected (although some target echo is lost). Each antenna consists of an array of 80 narrow slots skewed in angle (with alternating skew angles for squintless feed). Minimum range (short-pulse mode) is 50 yd; it is 300 yd in the long-pulse mode. Resolution: 75 and 650 ft, respectively. Reliability: 500 hr MTBF were required, 1200 hr demonstrated.

FASR antenna. (Westinghouse)

SPS-55 antenna, showing its back-to-back construction. (Cardion)

SPS-55 was developed by Raytheon but produced by Cardion; the first contract was let in June 1971. This radar was first used in quantity on board the U.S. *Spruance* class.

◆ SPS-58/62/65

Band: L (1215–1365 MHz)

Beam: 6×16 deg (12 deg in SPS-58) **Peak Power:** 12 kW

Gain: SPS-58A and -65: 23 dB, SPS-58: 26 dB

Pulse Width: 5 microsec (SPS-65: 7 microsec)

PRF: 2290 or 3050 pps (SPS-58A: 2285 or 3048 pps; SPS-65: 2315 or 3064 pps)

Scan Rate: 20 rpm (SPS-58A and -65: 15 rpm)

Antenna Dimensions: 126×76 in, with pedestal; SPS-58: 234×120 in

Antenna Weight: SPS-58A: 425 lb, with pedestal; SPS-58: 1200 lb; SPS-65: 439 lb. Below-decks weight: SPS-58: 2100 lb; SPS-58A: 1300 lb; SPS-65: 1594 lb

These short-range air-search radars, manufactured by Westinghouse, share the antenna of the standard SPS-10 surface-search set, the air- (actually horizon) search employing C- rather than L-band emissions. The transmitter is a 3-stage coherent klystron, for fully coherent operation (e.g., for MTI).

SPS-58 was developed at high priority after a series of studies of antiship-missile defense conducted in 1967–68. At that time Sea Sparrow was not considered effective against low-flying missiles because the associated search radar could not pick them out of the surrounding sea clutter. Sea Sparrow's CW doppler illuminator, however, could overcome clutter.

Contrary to published reports, the stimulus for the antimissile-defense program was not the sinking of the Israeli destroyer *Eilat* in October 1967. Rather, work on counters to Soviet antiship missiles began in January 1967, and the main stimulus seems to have been the need to protect shore-bombardment ships (Sea Dragon forces) off Vietnam. Presumably, the new threat consisted of shore-based missiles that could not be countered by carrier-based aircraft, the main earlier missile threat, the ASM, could be destroyed on board the bomber carrying it. A Fleet Anti-Missile Defense Executive Committee was formed in June 1967. Work continued through 1967, and undoubtedly the *Eilat* sinking encouraged this effort. It seems to have inspired special efforts to counter Komar- and Osa-class missile boats.

In 1967 all U.S. low-altitude naval search radars were simple pulse types, limited more by clutter than by the radar horizon. Even in calm weather, maximum range was typically 70% of the radar horizon, or about 14 nm for a destroyer. In rain or even moderately rough weather, clutter could preclude detection of a low-flying missile. The possible solutions were doppler, pulse doppler, pulse compression, and MTI radar; the performance of

Comparative coverage of SPS-65(V)ER (top) and SPS-65(V)1 and 2 (bottom). (Westinghouse)

the Tartar tracker (SPG-51) showed that pulse-doppler operation could succeed. In 1967 the main alternatives were modified fire-control systems (Mk 86 and the Signaal M20 series), a Westinghouse MTI radar, the Siemens pulse-doppler radar, an experimental Sanders radar called FAAR, and a power-driven version of the Sea Sparrow designator/illuminator.

The Siemens mobile pulse-doppler air-search radar (MPDR-45) was selected, for development by Westinghouse as SPS-58.

SPS-65 was first procured in FY75. In 1980 it was decided that all pre-FY75 U.S. SPS-58/58A/62 would be upgraded to SPS-65(V) capability through transmitter replacement and other field changes; all new carrier installations would be SPS-65(V)1s. SPS-58 was essentially a stand-alone system, but SPS-65 could feed directly into NTDS. It had ATD and was more reliable since the klystron of the earlier version was replaced by a solid-state driver. This radar also enjoys better ECM resistance. It employs MTI to reject clutter.

Early SPS-58s (and SPS-58Bs) used a separate antenna (AS-1067), but SPS-58A, -58C, and the subsequent SPS-62 and SPS-65 used the SPS-10 antenna, the usual feed horn of the surface-search device being replaced by a dual-feed waveguide horn. Maximum range is about 25 nm. SPS-58B and -58D have no displays but feed directly into NTDS, to trigger missile firing.

In 1979, Honeywell advertised the H-930 combat system, which incorporated an SPS-58 that automatically detected any target flying faster than an 80-kt MTI threshold. In this installation, the SPS-58 would have been mounted back to back with an SPS-55 surface-search radar. This SPS-58V radar had a 26-dB antenna (4×18 -deg beam) and an instrumented range of 125

SPS-65(V)ER antenna. (Westinghouse)

nm; scan rate was 15 rpm. Minimum range was given as 1 nm, and a 1-m² target could be detected at 66.4 nm. Azimuth accuracy was 0.5 deg, and range accuracy 1%. This version operated on any 1 of 6 selectable frequencies.

The Taiwanese Navy uses a stand-alone SPS-58, without any associated back-to-back antenna, as the missile detector for the Honeywell H930 fire-control system. This radar incorporates both MTI and ADT; the operator has only to press the firing switch. H930 Mod 1 has 3 channels, 1 Mk 35 optical system, and 2 CS/SPG-24 (similar to RCA HR-76) tracking radars. Reportedly the 2 SPG-24s are to be fitted with coaxial TV/IR trackers so that they can deal more effectively with sea-skimmers. These radars can also be used for low-level air search, to make up for the low data rate (19 rpm) of the SPS-58.

Westinghouse currently offers 3 versions of SPS-65: (V)1 for self-defense, (V)2 for fire control, and (V)ER for long (extended) range. All can be fitted with the company's solid-state L-band transmitter (SSTx), and all can be provided with a special anti-jamming frequency-agile mode (the radar automatically changes frequency based on its detection of the least-jammed frequency). (V)1 and 2 have a 25-nm instrumented range mode. The ER version has 3 range modes: 25, 50, and 100 nm.

As in the original SPS-58, these transmitters and signal processors can use the SPS-10 antenna. However, Westinghouse offers 2 alternatives. One is a dual-beam antenna for missile guidance, to detect high- or low-flying targets; this antenna requires additional signal processing. Another is a dipole-array antenna. In addition to the normal scan rates (15 rpm) for the 3 range modes, both the dual-beam and the dipole-array can be provided with an alternative high-speed mode.

(V)1 is the direct successor to the version originally developed as an acquisition radar for the Basic Point-Defense Missile System (SPS-58). (V)2 adds a fire-control interface group (FCIG) to (V)1, for ADT, manually initiated autotracking, NTDS symbology, target centroids, track history, and outputs suitable for gun and missile control. The (V)ER version, formerly SPS-58(LR), was announced in 1987. It has a higher-power solid-state transmitter and an enhanced signal processor. (V)ER can operate in short-, medium-, or long-range modes, and these modes may be timed for alternate scans. In long-range mode the radar uses a pulse-coded stretched pulse (pulse-compressed on reception); full MTI is provided out to 100 nm. The short-range mode is optimized for sea-skimmer detection within 25 nm.

SPS-65(V)1 and 2 use a 12-kW transmitter (average power 260 W); the ER version uses a 25-kW transmitter (average power 1200 W). Detection ranges on a 1-m² (Swirling case 1) target are, respectively, 23 and 61 nm. The ER version has an instrumented range of 100 nm, and it is frequency agile on a burst-to-burst basis. It employs digital MTI for clutter rejection. Elevation coverage is up to 16 deg in the (V)1 and 2 versions and up to 30 deg in the ER version. Accuracy is 1500 ft and 0.5 deg in (V)1 and 2, 608 ft and 0.5 deg in (V)ER. Resolution is 3000 ft in both cases, but azimuth (beamwidth) is 5.8 deg in the (V)1 and 2 versions and 3.5 deg in (V)ER. In all cases, the MTI improvement factor is 60 dB. The ER version employs variable PRF (300 to 625 pps), and the antenna's rotation speed is 10 or 20 rpm. Horizontal beamwidth is 3 deg.

Current MTBF for SPS-65(V)1 is 350 hr, and MTTR is less than 2 hr.

The new L-band transmitter can use existing SPS-6, -12, and -58 antennas, as well as the modified dual-frequency SPS-10 antenna used for earlier SPS-65 radars.

Data apply to a modified SPS-10B antenna. SPS-62, described officially as an "alarm radar," shared many SPS-58 components but had a modified receiver-processor and a new planar-array antenna (114 in wide, beam 5.5 × 21 deg, 12-kW pulses, 5 microsec long, PRF 2280 or 3040 pps). Development was abandoned in 1973 in favor of advanced versions of SPS-58. The relatively long pulse was probably compressed, for increased average power.

In U.S. carriers, SPS-58s with special separate antennas are being replaced by TAS Mk 23s (see below for description).

◆ SPS-64

Band: X (9345–9405 MHz) or S (3025–3075 MHz)

Beam: 4 alternative X-band slotted-waveguide antennas: (i) 1.9 × 22 deg (ii) 1.25 × 22 deg (iii) 0.9 × 22 deg (iv) 0.7 × 22 deg S-band slotted-waveguide antenna: (v) 2 × 25 deg

Peak Power: 3 alternative transmitters: (i) 20-kW fixed or tunable X-band, (ii) 50-kW X-band, (iii) 60-kW S-band

Gain: 28 dB **Pulse Width:** (a) 0.06 (b) 0.5 (c) 1.0 microsec

PRF: (a) 3600 (b) 1800 (c) 900 pps **Scan Rate:** 33 rpm

Antenna Dimensions: (i) 4 ft X-band only (ii) 6 ft (iii) 9 ft (iv) 12 ft (v) 6 ft **Antenna Weight:** (ii) 140 lb (iv) 332 lb

Raytheon's navigational radar for the army, navy, and coast guard has 3 alternative transmitters and 4 alternative antennas (as shown above). The main elements are (i) a high-powered S-band radar to detect surface targets out to 20 or 30 nm (AS-3195 antenna, RT-1241A transmitter-receiver); (ii) a high-resolution X-band navigational radar (6-, 9-, or 12-foot antenna); (iii) an interswitch unit that can connect any indicator/receiver/transmitter combination (so that the 12-ft antenna can be used for X- or S-band, for example); (iv) a RAYCAS V CIC indicator; (v) a RAYPATH indicator; (vi) an ESM interface; and (vii) a fire-control interface.

The RAYCAS V 16-in PPI is intended for use in a CIC; it is used in the (V)6 and (V)10 versions below. It can track up to 20 targets within 40 nm automatically, with direct readouts of target range/bearing and course/speed. Target true or relative vectors can be displayed on screen. Intercept course/speed are automatically calculated. Up to 20 ground-stabilized true marks (to permit on-screen marking of datum or reference points) can be displayed, plus up to 16 ground-stabilized navigational line segments (e.g., boundaries, fairways, danger zones). The indicator has automatic CFAR. As an option, programmable fairways/mapping stores up to 1500 geographic data points.

RAYPATH (12-in PPI, in the (V)11 version) automatically tracks up to 20 targets within 20 nm; automatically displays target CPA (TCPA), course/speed, and bow crossing distance; provides automatic warning when a target violates the CPA/TCPA threshold set by the operator; displays target true or relative vectors; and has true-motion and trial maneuver (to analyze proposed evasive action) modes.

RAYCAS and RAYPATH correspond to devices classified elsewhere as simple tactical data systems (e.g., CANE). Fire-control data can be transmitted to these indicators, and they in

SPS-64 on board the Coast Guard cutter *Bear*. The egg atop the bridge is a Mk 92 fire-control system for the 76-mm/62 gun forward. Also visible is the box containing an SLQ-32 ESM system, on a platform just aft of the bridge windows. The flat object atop the mast is a TACAN aircraft beacon. (U.S. Naval Institute)

turn can transmit data to a ship's fire-control system. A synchronization mode slaves X-band navigational radar transmission to the fire-control radar to avoid mutual interference.

The ESM interface (AM-6933) provides blanking pulse outlets for the X- and S-band radars, to avoid self-detection.

Versions (with Raytheon commercial designations in parentheses, where applicable):

(V)1 for the Coast Guard, with 6-ft X-band antenna (20-kW X-band transmitter) (RM 1220 6X). This is the radar in *Reliance*- and *Diver*-class cutters, and in patrol boats.

(V)2 for the Coast Guard, with 6-ft X-band antenna (two 20-kW X-band transmitter-receivers and 3 displays) (RM 1220 6X, RM 1620).

(V)3 for the Coast Guard, with two 6-ft X-band antennas (two 20-kW transmitter-receivers) (RM 1220 6X, RM 1220 6X RM16).

(V)4 for the Coast Guard, with one 6-ft X-band antenna and one 12-ft S-band antenna (20-kW X-band and 60-kW S-band) (RM 1220 6X, RM 1660 12S RM16).

(V)5 for the army, with one 6-ft X-band antenna (20-kW X-band transmitter) (TM 1620 6X).

(V)6 for the Coast Guard, with one 6-ft X-band and one 12-ft S-band antenna (50-kW X-band and 60-kW S-band transmitters and 2 displays) (RM 1250 6X, RAY CAS 1660 12S). This is the radar in *Hamilton*- and *Bear*-class cutters.

(V)7 for the Coast Guard, with one 6-ft X-band antenna (20-kW X-band transmitter) (RM 1225 6X).

(V)8 for the Coast Guard, with one 6-ft X-band antenna (20-kW X-band transmitter) (RM 1025 6X).

(V)9 for the U.S. Navy, with one 6-ft X-band antenna (20-kW X-band transmitter) (RM 1220 6X).

(V)10 for the Coast Guard, with two 6-ft X-band antennas (two 20-kW X-band transmitters and 3 displays).

(V)11 for the Coast Guard, with one 6-ft X-band antenna (20-kW X-band transmitter) (RAYPATH 1225 6X).

(V)12 for the army, a 10-kW X-band set (1210 4X).

(V)13 for the army, a 10-kW X-band set (1010 E 4X).

(V)14 for the army, a 10-kW X-band set using a radome (1010 E D).

(V)15 for the U.S. Navy, with one 6-ft X-band antenna (50-kW transmitter) (RM 1650 6X, RAY CAS V).

(V)16 for the army, with one 6-ft X-band antenna (50-kW transmitter) (RAYPATH 1650 6X).

(V)17 for the army, with one 12-ft S-band antenna (60-kW transmitter) (RAYPATH 1650 12S).

(V)18 for the U.S. Navy, with one 9-ft X-band antenna (50-kW transmitter) (RAYCAS 1650 9X NWU-51).

◆ SPS-67

This Norden solid-state radar is intended to replace SPS-10 on a one-for-one basis. SPS-67 uses the same antenna, the improvements being confined to the electronics of the transmitter, receiver, and display. The magnetron is the same as that of the SPS-55. SPS-67 is the first U.S. Navy radar built of standard electronic modules (SEMs) for commonality with future radars; Norden claims 92% SEM construction (including 46 types already approved, and only 29 new types), and 80% commonality to current navy sonars and to potential navy radars. Designed MTBF is 600 hr, and designed MTTR is 29 min, the short repair time being achieved partly by means of built-in test equipment.

The design provides for future addition of an automation module (digital MTI/ATD) to feed data into a combat system (IADT, as in SYS-1).

A new harbor-navigation mode (using a 0.1-microsec pulse) allows clutter-free detection of targets (buoys and small craft) at shorter range than is common with SPS-10. Tests have shown that buoys and small obstructions can be detected at 75 yd.

SPS-67 currently exists in 3 versions. (V)1 is the original type, essentially duplicating SPS-10 with more modern technology. (V)1 has demonstrated an MTBF of considerably better than 1000 hr and an MTTR of only 29 min. (V)2 replaces the original SPS-10 antenna with a nuclear-survivable (and much more reliable and maintainable) linear-array antenna. (V)2 should per-

form much better under conditions of extreme roll and pitch (e.g., in northern waters), and bearing accuracy is improved. (V)3, now under development for the *Arleigh Burke* class, has a 2/4-sec data rate, digital MTI (DMTI), ATD, and TWS. (V)3 is designed to provide digital data directly to fire-control, command-and-decision, and SYS systems. (V)3 shares the new (V)2 linear-array antenna.

◆ SPY-1/FARS

Band: S (3100–3500 MHz) (sustained coherent bandwidth 10 MHz, instantaneous 40 MHz) **Beam:** 1.7×1.7 deg

Peak Power: 4–6 MW (average power 58 kW) **Gain:** 42 dB

Pulse Width: 51, 25.4, 12.7, and 6.4 microsec (pulse-compression ratio 128:1) **PRF:** variable

Scan Rate: 1 horizon scan/min, 12 scans/min above horizon

Antenna Dimensions: 12 ft hexagon

Antenna Weight: 13,030 lb per face; below-decks weight 131,584 lb

SPY-1A, manufactured by RCA (as of 1988, this RCA division had been taken over by General Electric), is the S-band phased-array radar of the Aegis weapons system. Each of 4 faces is a 12×12 -ft [3.65×3.65 -m] octagon containing 140 array modules, each containing 32 radiating elements and phase shifters (a total of 4480; actually, because some modules are empty, there are 4096 transmitting and 4352 receiving elements, plus 128 auxiliary elements) driven by 8 transmitters. Array modules are paired to form receiving subarrays, and 2 such arrays are paired to form a transmitting subarray. Finally, these subarrays are grouped to form 32 transmitting and 68 receiving arrays, with separate receiving and transmitting terminals. Operation is monopulse. Total weight per face is 13,030 lb. The multiple beams are controlled by UYK-7 computers. The computer-controlled beam can update target positions several times per second, and over 200 contacts can be tracked simultaneously. The basic transmitter uses 32 crossed-field amplifiers, each with a peak power of 132 kW. Required power input is 490.9 kVA, compared to 64 kVA for the various versions of SPS-52, 65.8 kVA for SPS-48A and -48C, and 112 kVA for SPS-48E. For com-

Microwave "plumbing" in the back of an SPY-1 panel. See the illustration for SPG-62 (the associated target illuminator) for the outside of the radar. (U.S. Naval Institute)

parison, typical power inputs for 2D air-search radars are: 94.4 kVA for SPS-49; 15 for SPS-29/29E; 45 for SPS-37/37A; 21 for SPS-40; 27 for SPS-40A; 33.5 for SPS-40B,C,D; 45 for SPS-43/43A; 7 for SPS-58 and -65; 8.5 for SPS-58A.

SPY-1B (the first of which is on board CG 59) uses lighter-weight phase shifters, and the total weight per face is reduced to 7900 lb, compared to 16,970 lb for SPY-1 and 12,000 lb for SPY-1A. SPY-1D uses SPY-1B electronics but occupies only a single deckhouse, with a single radar transmitter. Each face of a SPY-1A has 4352 elementary radiators (subantennas) organized into 32 transmit subarrays and 68 receive subarrays. SPY-1B/D faces consist of 4350 radiators, plus 2 sidelobe-blanking antennas, but more compact wiring made it possible to divide the face into 2175 subarrays. Reducing each subarray from 64 to 2 elements eliminates grating lobes, making for sharper radar beams. Elements have 7- rather than 4-bit phase-shifting ferrites, for smoother electronic beam motion. The new array itself is much more nearly circular than the old one. As displayed in 1983, SPY-1B was expected to have 15-dB lower sidelobes and a better signal processor. Its transmitter tube was redesigned for a double duty cycle (with the same peak power), so SPY-1B could transmit longer pulses or more energy at higher elevation angles to counter diving missiles (such as AS-4/6) and jamming. The reduced sidelobes should reduce the effects of standoff jamming. VLSI electronics saves considerable weight and reduces the number of electronic cabinets from 11 to 5 (and weight from 14,700 to 10,800 lb). Better software should also improve ECM resistance against threats such as self-screening jammers and sophisticated repeaters.

SPY-1B introduces a new signal processor, smaller and lighter than its predecessors, but with improved performance and reliability; it is also less expensive, thanks to increased electronic integration. The new signal processor uses a channelized (parallel) architecture. Signals are received and processed in 4 separate channels: the main antenna reference (sum channel), azimuth and elevation difference channels, and a sidelobe-blanking antenna channel. Each channel is further divided into 4 parallel subchannels. All signals are digitized and processed for MTI, pulse compression, monopulse angle computation, main/sidelobe indication, missile processing, burn-through (ECCM) processing, and ECM analysis. This type of processing requires the use of VLSI electronics (the total number of separate digital modules falls from 3806 in SPY-1A to 1606 in -1B or -1D). A total of 11 microcomputers (16-bit Mil-Std-1750 type) are used.

The new SPY-1B transmitter consists of a TWT feeding 3 sets of paired crossed-field amplifiers, which in turn feed 2 sets, each of 16 crossed-field amplifiers, multiplexed to feed each pair of antennas (ultimately there is only 1 beam at a time). In SPY-1D, the 32 final crossed-field amplifiers are multiplexed between all 4 antenna faces.

SPY-1B introduces a direct missile up-link through the radar antenna, in place of the separate transmitters and antennas of the earlier -1A. SPY-1D will be the first version using the UYK-43 computer, which replaces the UYK-7 of the earlier versions. It also introduces the new standard display, UYQ-21, replacing the UYA-4 of the earlier SPY-1A. Late-production SPY-1Bs will also have UYK-43s and UYQ-21s.

GE is currently planning a post-processor upgrade for SPY-1B and -1D, in which a single module replaces 11 current modules and triples net performance. The upgrade should greatly reduce radar dwell time, hence allow the radar to track faster-moving targets. It employs an RCA control processor (RCP IIC), a Mil-Std-1750A computer using a special GE chip (CPU-SC-1750).

DDG 82 and later ships will be equipped with SPY-1E, which is intended for greater effectiveness against sea-skimmers.

The effect of electronic steering in both azimuth and elevation is to produce a very narrow pencil beam that can be steered randomly across the entire hemisphere. The radar can, therefore, search steadily, taking time out to track targets of interest by going back to dwell on the area around their last appearance.

SPY-1 reportedly scans a hemisphere of 175-nm radius while

using a single beam to search the horizon out to 45 nm for sea-skimmers.

Development began in 1965, and the system was first tested at sea in 1974. SPY-1A is the current production version, and SPY-1B is improved and simplified for later-production Aegis cruisers (from *Princeton*, CG 59, onward). SPY-1C was a proposed version for aircraft carriers. SPY-1D is the lighter-weight version for Aegis destroyers (*Arleigh Burke*, DDG 51, class).

The associated IFF interrogator is also electronically scanned. It is the Lockheed AIMS (AS-3134/UPX), which consists of 64 elements in a 12.5-ft ring (16 in high). The interrogator can operate in continuous, sector-scan, or jump-scan modes, shifting from beam to beam in 50 microsec. Beamwidth is 7×44 deg in any one of 1024 directions (so that a signal can be localized much more accurately than the beamwidth alone might indicate). The associated system is UPX-24(V), a central IFF (by Litton) that can integrate the outputs of as many as 4 unrelated radars.

FARS (Frigate Array Radar System) is an RCA proposal for an S-band system based on SPY-1, but with arrays only a quarter as large and a 2- rather than 4-channel signal processor. The transmitter will be driven by a TWT instead of the crossed-field amplifier of SPY-1, since less power is required. FARS was originally proposed for the projected German 4500-ton missile destroyer (which has presumably become Type 123); the company (now a division of GE) claims that FARS can fit ships as small as 3100 tons. FARS has also been proposed for the various NATO AAW programs. This system is compatible with both vertically launched Sea Sparrow and SM-2, and in 1987 RCA suggested that a mix of the 2 (4 Sea Sparrows per cell) was ideal for the Baltic. The SM-2s would keep most intruders out, and the Sea Sparrows were numerous enough to deal with leakers and with pop-up attackers. GE describes FARS's range as about 54% of SPY-1 (literally, the same number of units of range, but km rather than nm).

See also the Aegis system and the SM-2 missile entries below.

◆ UPS-3

Band: S **Beam:** 8×17 deg **Peak Power:** 230 W

Gain: 22 dB **Scan Rate:** 60 or 90 deg/sec

Antenna Weight: 56 lb (plus 45.2 lb pedestal and 25 lb quadrupod)

This lightweight radar, by Lear Astronics, was developed to alert Stinger operators assigned to provide forward-area air-defense for the U.S. Army's Light Divisions. UPS-3 is included here because it has been supplied to the navy to support Stinger missile operators on board ships. UPS-3 is designated TDAR (Tactical Defense Alert Radar) and can be set up by 2 people in less than 10 min. Maximum range is 20 km, and maximum target altitude 10,000 ft. Solid-state electronics makes for very high reliability (MTBF is 2180 hr). The antenna is a slotted waveguide. The LED display identifies a target as either a fixed or rotary wing aircraft, presumably on the basis of a moving target indicator (MTI).

This radar was based on the Israeli EL/M-2106 point-defense alert radar.

◆ Advanced Surveillance Radar: B-1B Radar

Under the FY89 program, work began on a feasibility study to test the B-1B X-band radar (Westinghouse APQ-164) at sea. This radar uses the TWT transmitter of the APG-68 radar of the F-16 plus a new processor and a new phased-array antenna, developed under the U.S. Air Force EAR (electronically agile radar) program. APQ-164 has a synthetic-aperture ground-mapping mode. The antenna is a 2D phased array, 559×1118 mm, controlled by 1526 phase shifters. In the B-1B, the antenna can be locked into 1 of 3 positions, the FOV being about 105 deg wide when pointed to either side, or 120 deg wide when pointed dead ahead. It scans ± 60 deg in elevation.

Presumably the B-1B radar is attractive mainly as an example of a new phased-array system. It is also relatively stealthy. As used by the bomber, it stores successive terrain maps in its computer, pausing between updates (which are typically made

at 3- or 4-sec intervals) rather than continuously scanning the ground. The memory suffices for terrain-following.

In the B-1B, the radar consists of 2 separate units with a single antenna, 1 unit on standby. It was first tested in July 1984. The APG-68 is a development of the earlier APG-66 (see W-160, below) with a programmable signal processor, a dual-mode transmitter, and a single-unit all-digital processor, all instructions being stored in a 512 kword EEPROM memory. It has 22 radar modes, presumably including Doppler beam-sharpened ground mapping (for a claimed eightfold improvement in ground mapping resolution). As an indication of computer power, TWS capacity is 10 targets.

Westinghouse has proposed a derivative of the B-1 radar for the 2-face phased array of its NAAWS radar.

◆ FAST, FLEXAR, MBAR

None of these advanced radars has been adopted. For details, see the previous edition.

◆ Furuno Radars

The U.S. Navy now uses Japanese commercial (Furuno) navigational radars, as in the past it typically used Pathfinder 1500s. Furuno radars are now very common in commercial service (e.g., on board fishing boats). The great advantage of using standard commercial radars on board combatant ships is that ESM surveillance systems cannot distinguish ships navigating with such radars from noncombatants. It seems likely that the Furuno was the Japanese radar planned for the abortive SWCM, the special warfare craft, medium.

U.S. aircraft carriers use the Furuno 904. Some Coast Guard cutters have Furuno 1510s. These radars are on board at least the submarine *Sunfish* (SSN 649), the destroyer *Hewitt*, the submarine tender *Emory S. Land*, and the tanker *Monongahela*. Some of the smaller Furunos are used on board coastal (special warfare) craft, such as 65-ft patrol boats and 36-ft Sea Foxes. These standard commercial sets have not been assigned AN/SPS designations.

Radar characteristics are listed here because, although the radars are of Japanese origin, their main military user is the U.S. Navy.

Model:	8050D	904
Band:	X	X
Beam:	(i) 1.8×25 deg (ii) 1.23×25 deg (iii) 0.95×20 deg	2.4×25 deg
Peak Power:	5 kW	3 kW
Pulse Width:	(a) 0.08/0.3 microsec (b) 0.3/0.6 microsec (c) 0.6/1.2 microsec (d) 1.2 microsec	(a) 0.08 microsec (b) 0.5 microsec
PRF:	(a) 2100 pps (b) 2100/1200 pps (c) 1200/600 pps (d) 600 or 500 pps	(a) 2500 pps (b) 840 pps
Scan Rate:	24 rpm	24 rpm
Antenna Width:	(i) 4 ft (ii) 6.5 ft (iii) 8 ft	3 ft 5 in

In this list, 8050D is taken as typical of small-ship Furuno radars. There are 3 alternative slotted-waveguide antennas, denoted (i) through (iii). Some models have higher-powered (10- and 25-kW) transmitters. The 1500 series matches 8050 series characteristics.

These radars use raster-scan (TV-like) displays rather than the previous standard PPIs. They are digitized, with sufficient memory to store the radar picture and display it in flicker-free form. Echoes are sufficiently persistent to show target tracks, and the radar controls are typically provided in touch-pad form. Display options in the 1510 include an off-centered display, a zoom display (the area of interest can be doubled without changing radar range [i.e., PRF]), and echo trail (as much as 1 min of target history can be displayed). Echoes are sorted into 8 brightness categories; the manufacturer claims that this feature prevents

targets from fading in and out, as in radars with a single displayed brightness level. Signal processing includes echo stretching and echo averaging, plus a radar interference rejector.

The 8000 series has a 12-in diagonal CRT, equivalent to a 180-mm (7.1-in diameter) PPI. The 904 has a 10-in diagonal 3-color CRT. The 1500 series has a 15-in diagonal CRT, equivalent to a 10-in diameter PPI.

◆ Pathfinder 1500

This Raytheon commercial radar was very widely installed on board U.S. warships during and after the Vietnam War, supplementing standard naval surface-search sets for navigational purposes. At the time Pathfinder was also an extremely popular civilian radar, and its use may have been intended to confuse some hostile ESM operators.

Typical characteristics (1500B): X-band, 7 kW, pulse width 0.14 microsec, PRF 750 or 1500 pps, 48-in slotted-waveguide, 2×20 -deg beam.

Raytheon also produced a radome-enclosed 1900, which was installed on board many lesser craft. Typical characteristics: X-band, peak power 5 kW, pulse width 0.16 microsec, PRF 2000 pps, scan rate 20 rpm, reflector 33 in wide, beam 3×27 deg.

◆ Raytheon R20/R40/R70/R80/ST Series Navigational Radars/SPS-69/Radar B

Band: X (9380–9440 MHz) **Beam:** 4×25 deg
Peak Power: 4 kW
Pulse Width: (i) 0.08 (ii) 0.25 (iii) 0.5 microsec
PRF: (i) 2250 (ii) 1500 (iii) 750
Antenna Dimensions: 24 in **Scan Rate:** 24 rpm
Antenna Weight: 20.9 lb

Data above apply to R40X. Mode (i) is used for 0.125-, 0.25-, 0.5-, 0.75-, and 1.5-nm range scales; (ii) for 3- and 6-nm; (iii) for 12-, 24-, and 32-nm (12-, 24-, and 48-nm in R41X). R41X's beam is 2.2×30 deg. R40X uses a radome-enclosed antenna; R41X is an open array (slotted waveguide). R20X and R21X have the same characteristics but use smaller displays (7 in rather than 10 in on the diagonal, but with the same display resolution). They have shorter maximum range (24 nm for R20X, 32 nm for R21X). Data for the larger radars of the series (R70, R80, and Pathfinder ST series) are given below.

These radars are being purchased by the navy and coast guard, largely under the navy's Radar B program (Radar A is the full surface-search set, such as SPS-55 or -67). In mid-1990 the U.S. Coast Guard awarded Raytheon a 3-yr contract for 758 R41X radars, to replace existing SPS-66s and -66As (Pathfinder 3100s). This program was originally designated SPS-XX. It is now SPS-69.

The navy's B-series radar is a navigational set with true-bearing capability. It is intended as the primary radar for smaller units such as tugs (ATS), salvage ships (ARS), and minesweepers (MSO), and as a secondary radar for larger combatants (carriers, cruisers, destroyers, frigates). As of the spring of 1990, the only authorized class B1 radar was SPS-64(V)9, replacing Pathfinders, LN-66, and RAYCAS radars. SPS-64(V)15 has not been approved, and sets installed will be replaced by (V)9 as soon as SPA-25G consoles with collision-avoidance capability are installed. However, the Pathfinder ST display is being married to existing SPS-64s (see below).

Category B2 is a low-power relative-bearing radar for coastal units such as LCUs, YTBs, and YOGs. Unlike B1, it has not been subject to centralized purchase. Instead, this type of radar is bought independently by type commanders. There were 2 attempts to formalize the process with an RFP. About 1982–83 a source selection was abandoned when Furuno protested. Late in 1988 the Raytheon R70A was very nearly chosen, but the navy decided instead to decentralize the B2 program. Most such radars are now Raytheon R40 (with a 24.4-in radome antenna) or R41 (with an open 46.1-in slotted-waveguide antenna). The current versions, R40X and R41X, were announced in March 1990. Both share the same transmitter and receiver. The raster-scan display (610×496 pixels) is 10 in along its diagonal and

shows data in 8 levels of brightness. Range resolution is up to 30 m [32.8 yd], and bearing accuracy is within 1 deg. The presentation can be off-centered by up to 66% of radius (except in maximum range scale). There is also a zoom mode: any area of the screen can be enlarged to fill the screen. A unique "sleep mode," in which the radar switches on and off for a periodic check on its surroundings, would seem to be particularly useful for submarine applications (it is intended for sailboats, which have limited power resources).

R41 is typically chosen for harbor craft and small boats, but it (as well as the smaller R20 series) is also used on board submarines as a backup to their BPS-series radars. On a submarine, a commercial navigational radar is also valued because it provides no military-style electronic emissions.

About 1000 R70As (basically updated SPS-66) are in service as small-boat radars in the navy and the coast guard. The R70 series has a common 12-in raster-scan display (525 × 640 pixels, 16 video levels), with different transmitters and antennas:

	Power	Radome	Beam
R70A	4 kW	3 ft	2.8 × 25 deg
R71	4 kW	3.5 ft	2.4 × 30 deg
R72	10 kW	3.5 ft	2.4 × 30 deg
R73	10 kW	4 ft	1.9 × 25 deg
		6 ft	1.2 × 25 deg
R74	10 kW	8 ft	2.6 × 30 deg
		10 ft	2.4 × 30 deg

Maximum range is 48 nm for 4 kW, 72 nm for 10 kW. All but R74 (S-band) are X-band radars. Beamwidths are given above. As in the R20 and R40 series, pulse width and PRF vary with range scale. There are normal and long-pulse operating modes:

For the 4 kW X-band transmitter (R70A):

Pulse Width	PRF	Range Scale
0.08 microsec	3072 pps	0.25–1.5 nm
0.25 microsec	1500 pps	3–6 nm
0.7 microsec	750/500 pps	12–24/48 nm
0.25 microsec	768 pps	1.5 nm (long pulse)
0.5 microsec	512 pps	3–6 nm (long pulse)

For R71, PRFs corresponding to these pulse widths and ranges are, respectively, 2000, 1500, 750, 500, 1500, and 750. These figures also apply to the 10-kW R72.

For the 10 kW radars (R73 and R74):

Pulse Width	PRF	Range Scale
0.08 microsec	2000 pps	0.25–1.5 nm
0.4 microsec	1500 pps	3–6 nm (1.5 nm long pulse)
0.8 microsec	750 pps	12–24 nm (3–6 nm long pulse)
1.2 microsec	500 pps	48–72 nm

Range resolution is better than 30 m [99 ft], and bearing accuracy is better than 1 deg.

The next step up, R81/R82/R84, has a maximum range of 96 nm. A few of these radars are in naval service, for workboats, ocean-going tugs, and patrol boats. R81 is a 10-kW X-band radar, R82 a 25-kW X-band radar, and R84 a 10-kW S-band radar. Each has 4 or 5 pulse lengths plus 3 long-pulse modes. Antennas: R81, 4 ft or 6 ft (1.9 or 1.2 × 25 deg); R82, 6 ft or 9 ft (1.2 or 0.8 × 25 deg); R84, 8 ft or 10 ft (2.6 or 2.4 × 30 deg). The display is a 928-line raster-scan CRT (14 in diagonal, with 16 video levels).

Pulse modes for R81:

Pulse Width	PRF	Range Scale
0.08 microsec	2000 pps	0.25–1.5 nm
0.4 microsec	1500 pps	3–6 nm (1.5 nm long pulse)
0.8 microsec	750 pps	12–24 nm (3–6 nm long pulse)
1.2 microsec	500 pps	48–96 nm (12–24 nm long pulse)

Pulse modes for R82:

Pulse Width	PRF	Range Scale
0.08 microsec	2000 pps	0.25–1.5 nm
0.25 microsec	2000 pps	3 nm (1.5 nm long pulse)
0.75 microsec	1000 pps	6–12 nm (3 nm long pulse)
1.0 microsec	750 pps	24–48 nm (6–12 nm long pulse)

Pulse modes for R84:

Pulse Width	PRF	Range Scale
0.08 microsec	3104 pps	0.25–1.5 nm
0.4 microsec	1552 pps	3–6 nm (1.5 nm long pulse)
0.8 microsec	776 pps	12–24 nm (3–6 nm long pulse)
1.2 microsec	517 pps	48–96 nm (12–24 nm long pulse)

The most sophisticated radar in the series is Pathfinder ST. This radar is currently being evaluated on board the coast guard cutter *Reliant*. Pathfinder ST is a series of S- and X-band ARPA radars with 25- and 34-cm ARPA PPIs capable of tracking 20 targets automatically. Targets are manually acquired using a trackball or automatically acquired using true or relative acquisition zones. Target true wakes are used to indicate target speed and direction. The S-band version can be fitted with a 30-kW below-deck or a 10-kW above-deck transmitter, and with a 12-ft antenna. The X-band version uses a 25-kW transmitter and a 7- or 9-ft antenna. Other characteristics:

	S-band	X-band
Antenna:	12 ft	9 ft
Beam:	1.9 × 30 deg	1.0 × 25 deg
Gain:	28 dB	28.5 dB
Scan Rate:	(all) 22/26 rpm (50/60-Hz power)	
Pulse Widths:	(i) 0.75 (ii) 1.0	(i) 0.08 (ii) 0.25 microsec
PRFs:	(i) 1000 (ii) 750	(i) 3000 (ii) 2000

(aloft transmitter)	386 lb	158 lb
		148 lb
		161 lb

All use raster-scan displays (1024 × 768 pixels). Range scales: S-band: 6, 12, 24, 48, 96 nm; X-band: $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, $1\frac{1}{2}$, 3 nm. Minimum range is 27 yd in all cases, and range resolution is 0.3% or 4 yd, whichever is greater. Bearing accuracy is 1 deg, and bearing resolution is 0.3 deg.

The ST digital ARPA display is being married to SPS-64(V)10 radars on board several Atlantic carriers. At present the *America*, *Eisenhower*, and *Kitty Hawk* all have Pathfinder ST displays (M25 in the *Eisenhower*, M34 in the others).

◆ Danish Coastal Radar

ISC Cardion developed this unattended-site gap-filler radar for Denmark under a 1980 NATO contract. It searches for low-fliers and surface targets; its beam can be tilted by remote control. It has an 8 × 16-ft double-curvature reflector with an omnidirectional antenna for sidelobe suppression in the associated IFF. The transmitter is a TWT, and the waveform is coded for pulse compression. The transmitter (less than 100-kW peak power, 1% duty cycle) can operate at a fixed frequency, or in burst or frequency-agile modes; a different mode can be selected for any of 4 quadrant sectors. Processing includes digital MTI, and ADT can be added, and the radar can distinguish air from surface targets. As of 1988, 6 were in service and 2 more were ordered.

◆ Falcon

Falcon is ITT-Gilfillan's C-band pulse-compression (2 alternative compression ratios) coastal-surveillance radar. Development began in 1981, and by 1988 nearly 50 copies were on order (or had been delivered) for 5 countries. This radar was designed specifically for coast defense, the main desiderata being clutter rejection (against both rain and the sea surface) and reliability. High frequency and relatively short pulses make for high resolution so that the volume around the radar can be split into small resolution cells, to be processed individually. The man-

Cardion coastal radar. (ISC Cardion)

Manufacturer claims that relatively inexpensive solid-state electronics makes such processing economical. Dual feed horns (one 4 deg higher than the other) produce high and low beams simultaneously, for air and surface coverage. The high beam improves detection at short ranges and high elevation, where the

Falcon coastal radar. (ITT)

target would otherwise be in a low-gain part of the beam. Polarization can be chosen (horizontal or circular) to limit rain clutter, and doppler processing (biased toward low-velocity echoes) separates moving targets from background clutter. Targets are detected and tracked automatically out to 100 km (an optional extension to 160 km is available), and from sea level to 10,000 ft.

Falcon is frequency-agile over a 500-MHz band (48 channels). When doppler processing is being used, the radar hops in 4-pulse bursts. Radar characteristics: beam $1.25 \times \csc^2$ to 25 deg; peak power 60 kW (average 1.5 kW); instrumented range 100 or 160 km (corresponding to PRFs of 1500 and 9375 pps, respectively). Accuracy (resolution) is 20 (85) m, 0.2 (2.4) deg. Scan rate is 6 or 12 rpm. The system can maintain 100 target tracks simultaneously.

◆ UWB (Impulse) Radar

There was speculation that a new type of radar, UWB (ultrawide band), could be used to defeat stealth measures, following a June 1989 Los Alamos report prepared for NOSC. The premise of UWB is that, although an airplane or a missile may be stealthy over a limited band of radar wavelengths, any stealth scheme will break down if illuminated over a sufficiently wide bandwidth. Instantaneous radar bandwidth is inversely proportional to the width (duration) of the radar pulse, so a UWB radar is inherently a very short pulse radar, typical pulse widths being measured in picosec (thousandths of a nanosec, i.e., millionths of a microsec). Because its power is spread over so wide a frequency range, a UWB radar must produce a very high peak power, typically in the GW (thousands of MW) range.

Stealth shaping techniques, which are apparently inseparable from current stealth programs, defeat radars by diffusing their echoes. The echoing areas on the airplane or missile are several cm across, and the average shape suffices to limit direct reflection. A UWB would overcome this technique in 2 ways. At one end of its spectrum, its signals would have such short wavelengths that they would hit the inevitable small irregularities in the surface of the stealthy object, and some energy would be reflected. At the other end, they would be so large that their signals would be averaged over very large areas of the radar target, and they, too, would be reflected. The latter is an extension of the argument, made by stealth critics, that longer-wavelength radars will easily defeat stealth shaping and current radar-absorbing materials.

The UWB signal can, in theory, exploit any resonance or irregularity or edge in the target and, thus, may be able to return a large signal even from a carefully designed stealth aircraft or missile. Much depends, however, on how much energy is available in the usable radar band, and on how well the echo can be exploited. It might be argued that any particular stealthy object should be vulnerable to detection at particular unconventional radar frequencies and, therefore, that UWB is far too exotic to be worthwhile (at least for this purpose); however, it would be difficult to predict the precise characteristics of an enemy stealth airplane or missile.

UWB should have improved imaging capability because of its very short inherent range resolution (a result of its short pulses). The same characteristic should also make for reduced multipath through range-gating. Commercial UWB, which has been available for some time, has proven successful in penetrating foliage, earth, and even walls.

The principal technological issues in high-powered UWB (which does not yet exist) are probably the ability to switch very high power in a very short time (most likely using a short laser pulse) and the ability to exploit the resulting broad-band radar echoes, e.g., for imaging.

FIRE-CONTROL RADARS

◆ Mk 13

Band: X Beam: 0.9×3.5 deg Peak Power: 50 kW
Pulse Width: 0.3 microsec PRF: 1800 pps
Antenna Dimensions: 8×2 ft

The battleship *Iowa* shows her Mk 13 radar, in the long nacelle above her range-finder, 1986. The mast above carries SPS-49 and SPS-67 (for surface search). (Author)

The fire-control radar of the *Iowa*-class battleships is mounted atop their Mk 38 main-battery directors. Mk 13 is also installed on board the 2 reserve cruisers armed with 8-in guns. The antenna rocks back and forth inside its radome to scan in bearing over a 5.75-deg sector to either side (to achieve the 2D equivalent of conical scanning). Tracking range is 50,000 yd; range accuracy is 15 yd $\pm$ 0.1% of range. This radar (or Mk 8 Mod 3, its equivalent) also equips the Chilean cruiser *O'Higgins* (on her 2 Mk 34 main-battery directors).

◆ Mk 25

Band: X **Beam:** 1.6 deg **Pulse Width:** 0.25 microsec
Peak Power: 250 kW **Gain:** 39 dB **PRF:** 1320 pps
Antenna Dimensions: diameter 60 in **Antenna Weight:** 625 lb

Mk 25, the dish antenna radar associated with the World War II Mk 37 GFCS, employs spiral scanning (over a 12-deg cone) to acquire the target and conical scanning (over a 2.6-deg cone) to remain on target. Accuracy in bearing is 0.1 deg. For spotting, it has a 10-deg FOV. Angular resolution is 1.3 deg, and range accuracy is 15 yd $\pm$ 0.1% of range. Maximum tracking range is 100,000 yd. The antenna, but not the feed system, was also used in the later SPG-53.

Tests were completed in 1947, and over 400 of these radars were built. The only examples in current U.S. service are on board the 4 *Iowa*-class battleships, but Mk 25 equips many former U.S. destroyers in foreign service.

◆ Mk 26

Band: S (about 3000 MHz) **Beam:** 10 deg **Peak Power:** 50 kW
Gain: 26 dB **Pulse Width:** 0.5 microsec **PRF:** 540–660 pps
Antenna Dimensions: 36 in (truncated paraboloid)

Mk 26 is the range-only radar of the Mk 52 FCS, which survives on board some former U.S. destroyer escorts. Range on a bomber at 10,000 ft is 15,000 yd; range on a fighter at 1000 ft, 700–12,000 yd; range on a ship, 400–25,000 yd. Maximum tracking range is 27,500 yd. Range resolution is 200 yd (accuracy is 100 yd).

Mk 25 radar atop a Mk 37 5-in director on board the battleship *Wisconsin*, 1988. SRBOC chaff-launching mortars are visible to the right, on deck. (S. Terzibaschitsch)

◆ Mk 28

Band: X **Beam:** 6.5 deg **Peak Power:** 30 kW **Gain:** 27 dB
Pulse Width: 0.5 microsec **PRF:** 1800 pps
Scan: conical (2.3 deg) at 30 Hz
Antenna Dimensions: 45 in diameter

This U.S. World War II radar survives only on board the Chilean cruiser *O'Higgins* in her Mk 33 and Mk 57 (light anti-aircraft) directors. Mk 28 was a lighter alternative to the contemporary 5-in fire-control radar, Mk 12/22 (which was replaced by Mk 25). A fighter could be detected at 15,000 yd.

◆ SPG-34/Mk 34/SPG-50

Band: X (8740–9168 MHz) **Beam:** 2.5 deg **Peak Power:** 50 kW
Gain: 36 dB **Pulse Width:** 0.3 microsec **PRF:** 1800 $\pm$ 180 pps
Scan: conical (3.9 deg total coverage at 29 Hz)
Antenna Dimensions: 40 in diameter

SPG-34 is the radar of the World War II Mk 57 and Mk 63 FCSs; it appeared in 1953 as a revised version of the wartime Mk 34, with a larger antenna (40 vs. 30 in) and better facilities for target designation and acquisition. Targets are acquired using a 12.6-deg spiral scan (at 2 Hz). Tracking is by conical scan. Range resolution is 200 yd (accuracy is 15 yd $\pm$ 0.1% of range). Maximum displayed range is 60 kyd. Maximum range rate is 843 yd/sec (approximately 1500 kt). SPG-34 is similar to Mk 34 Mod 17 except for some repackaging below decks.

SPG-50 superseded SPG-34 in Mk 63s installed after about 1956. It has very similar characteristics, operating at a slightly higher frequency (8600–9600 MHz) and with a slightly shorter pulse (0.25 microsec) at a slightly higher pulse rate (2000 $\pm$ 200 pps). Total conical scan coverage for tracking is 4.1 deg, and targets are acquired by spiral scan over 12.6 deg. In contrast to SPG-34, SPG-50 uses a tunable magnetron as its power tube. Unlike SPG-34, it has automatic range designation and range

tracking; range and range rate are generated in the radar and sent directly to the gun sight. Typically, the ranging mechanism is controlled by a ship's target-designation system, but bearing and elevation data are inserted manually either by the director or the radar operator. Maximum range is 34,500 yd; minimum is 300 yd. Maximum range rates are -800 or $+350$ kt. SPG-50 has many components in common with SPG-53.

◆ SPG-35

Band: X (8.5–9.6 GHz) **Beam:** 2 deg **Peak Power:** 50 kW
Gain: 37.5 dB **Pulse Width:** 0.1–0.15 microsec **PRF:** 3000 pps
Scan: conical (3 deg) **Antenna Dimensions:** 48 in diameter

SPG-35 is the radar of the Mk 56 FCS. Accuracy is $20 \text{ yd} \pm 2.5\%$ of range. Resolution is 35 yd and 1.5 deg. Limits: tracking 100 deg/sec in train, 35 deg/sec in elevation. Maximum tracking range is 30,000 yd. In acquisition mode, the radar spiral scans over a 12-deg cone.

◆ SPG-51

Band: C (track) X (illuminate)
Beam: 1.6 deg (track)
 0.9 deg (illuminate) with 80 deg ancillary
Peak Power: 81 kW (track), 5 kW (illuminate)
Gain: 39.5 dB (track), 45 dB (illuminate)
Pulse Width: 2.1–3.2 microsec (track)
PRF: 4.1 kHz (surface mode), 9.5–16.7 kHz (air mode)
Antenna Dimensions: 92 in diameter

Data apply to SPG-51D (AS-2234 antenna). The radar consists of a C-band pulse-doppler monopulse tracker (with a 4-horn feed) and an X-band illuminator (CWI), both sharing a common reflector structure but using individual feeds and reflector surfaces (a horizontally polarized X-band wire-grid reflector embedded in dielectric material on its face). SPG-51 differs from other high-PRF radars in using multiple medium PRFs to combine conventional range tracking with doppler clutter rejection. The output of the monopulse cluster is fed into a rotating comparator, so in effect the radar tracks by conical scan on receive only (COSRO).

The ancillary antenna mentioned above provides the rear reference signal to the missile; it has a 12.5-dB gain.

The original SPG-51 had only a 2-kW CWI transmitter, which was marginal for the improved (17.5 nm) Tartar.

SPG-51A introduced a 5-kW CWI transmitter.

SPG-51B (1963) added a velocity tracking capability (speed gate) enabling the radar to track through clutter and at higher noise levels. The speed gate is an electronically tunable narrow-band filter (300 Hz rather than the original 7.1 kHz), which the

system uses to reject all signals outside a very narrow doppler pass band. Tracking range increases to 200,000 yd. SPG-51Bs in U.S. service were modified to SPG-51C standard. This radar survives on board the missile destroyer *Du Chayla* and on board the Japanese *Amatsukaze*.

SPG-51C introduced automatic acquisition and tracking, improved ECCM features, clutter rejection, and multiple target resolution as well as greater reliability. The data converter, which correlates all target information to make the logical decisions to acquire targets and maintain automatic 3D track, is solid-state rather than vacuum tube (as in SPG-51B) and has a new self-test feature. Maintenance adjustments are reduced from 83 to 6. The radar also has 2 new modes (reflecting contemporary concern with Soviet missile-attack boats and their weapons): surface acquisition and track, and horizon search. In surface-acquisition-and-track mode, noncoherent video is displayed on a B-scope to permit acquisition of a target too slow to be detected automatically by its doppler-shifted echo. The antenna is held fixed at 0-deg elevation, and PRF held at a value giving unambiguous range track out to the radar horizon. Horizon search mode is protection against low fliers (such as anti-ship missiles): the director scans the full 360 deg at a fixed elevation angle, with scan speed and range gate set to detect, acquire, and engage targets at Mach 1.2 or less without the delays inherent in the usual designation-and-acquisition process. The radar console has a second scope with a B-scan for use in the surface and horizon-search modes. The data converter of this version was designed for relatively simple conversion to all-digital fire-control operation.

Recent SPG-51C modifications are

Phase IIA: improved ECCM, solid-state, switchable, transmit-receive tube; improved maintainability

Phase IIB: improved CWI power supply; solid-state, stable master oscillator; replacement of klystron with permanent magnet-type tube

Phase IIC: improved DC gyros to eliminate 30-min warmup; replacement of amplidyne with solid-state drivers.

This version is standard in the *Adams* and *Brooke* classes, replacing the earlier SPG-51B. Peak power is 30 kW, and antenna (AS-2649) diameter is 91 in. This is the version on board the Spanish *Baleares* class, and it currently also serves in the Australian, French, German, Italian, Japanese, and Dutch navies.

SPG-51D, the latest operational version, was introduced with the Tartar-D (digital Tartar) FCS (*Virginia*, *California*, and *Kidd* classes). It introduced a new off-mount, frequency-agile, pulse tracking transmitter (which could change frequency up to 4 times/sec) with more than a fivefold increase in power over its predecessors; a new free-rotating, dual-frequency rotary joint; and a new antenna system with a fivefold increase in gain. SPG-51D employs a new pulse-shaping technique that makes for a cleaner spectrum and thus for less interference with other radars. This version is on board the Italian *Animoso*-class missile destroyers.

SPG-51 is unique in the fleet in using doppler to acquire targets and reject clutter and chaff. Transmitted frequencies are such that the operator can hear the doppler signature, and an experienced operator can use this aural signature to distinguish the type and number of targets. To make fullest use of the operator's capabilities, the console (at least in SPG-51D) allows overriding of the angle and range trackers of the system. Tartar-D continuously calculates expected target motion, assuming that the target is flying in a straight line, and uses measured range and angular position to update it. That reduces tracking bandwidths and, thus, reduces tracking line-of-sight noise. It also provides an automatic range computation when jamming denies range data (but provides angle data).

SPG-51E, which was not built in quantity, was intended as a "universal fire-control radar," to control Talos as well as Tartar (now Standard) missiles.

SPG-51 radars are manufactured by Raytheon.

SPG-51 Standard MR directors, USS *Mississippi*, June 1988. (Stefan Terzibaschitsch)

◆ SPG-52

Band: Ku (16.3–16.5 GHz) **Beam:** 5 deg
Peak Power: 50 kW **Gain:** 30 dB
Pulse Width: 0.5 microsec **PRF:** 1500 pps (modulation 400 Hz)
Antenna Dimensions: diameter 12 in **Antenna Weight:** 2 lb

SPG-52 is the radar associated with the Mk 70 GFCS. Manufactured by Lockheed Electronics, SPG-52 must have been one of the earliest practical applications of Ku-band technology. SPG-52 was a range-only radar, with no means of tracking, functionally equivalent to Mk 26, above. Maximum range was 10,000 yd. Total weight was 1177 lb, compared with 890 lb for Mk 26.

◆ SPG-53

Band: X **Beam:** 1.6 deg (spiral or conical scan)
Peak Power: 250 kW **Gain:** 39 dB
Pulse Width: 0.25 microsec **PRF:** 1000 pps
Antenna Dimensions: diameter 60 in
Antenna Weight: 163 lb (antenna only); total 5000 lb

Data apply to SPG-53A.

SPG-53 is the radar of the Mk 68 GFCS on board many U.S. frigates, destroyers, and cruisers; it was superseded by the SPG-60 and SPQ-9 of the Mk 86 system. This radar uses spiral scan (11.6-deg cone at 2 Hz) for target acquisition and conical scan (3.1-deg cone at 30 Hz) for tracking. There is a 4000-yd precision sweep.

SPG-53, for gun ships (*Forrest Sherman*-class destroyers), has an instrumented range of 50,000 yd. Peak power is 50 kW, and PRF is 1320 ± 132 pps.

SPG-53A, for missile ships, has a maximum instrumented range of 120,000 yd. Accuracy is $10 \text{ yd} \pm 0.025\%$ of range. Resolution is 80 yd and 1.3 deg. Tracking limits are 50 deg/sec in train and 30 deg/sec in elevation.

During the early 1970s SPG-53As were fitted with RSPE (radar signal processing equipment), a form of ATD intended to deal with faster targets (without RSPE, acquisition required the coordinated efforts of 3 operators). A target in the spiral-scan acquisition field of the radar is automatically detected and within 4 msec is gated in range. RSPE generates train and elevation error signals that drive the radar antenna. When the target is centered in the beam, the radar automatically switches to conical scanning, and the normal range and angle tracking circuits lock on. The entire process takes less than 5 sec. RSPE also incorporates antijam features; for example, it automatically rejects pulses with inappropriate pulse widths.

SPG-53B was SPG-53A with CWI for Tartar missile control. It was conceived for converted missile destroyers (DDG 31–34), which could not accommodate 2 SPG-51s. It was associated with GFCS Mk 68 Mods 9 and 10. The illuminating signal was provided by an off-mount version of the 5-kW SPG-51B illuminator, with improved reliability. The new antenna (AS 1868 rather than AS-515A) comprised 2 coaxial paraboloid antennas of different curvature and focal length and could, thus, accommodate 2 different feeds. CWI was fed through a horn mounted in front of the reflector, vertically polarized (it used the vertical wires of the front parabolic surface). Gain was 38 dB for the main (tracking) radar and 41.6 dB for the CWI antenna; diameter was 64 in (318 lb for the antenna alone). Mk 68 Mods 9 and 10 used an additional Mk 118 Mod 2 computer for launcher and missile orders.

SPG-53C is an analogous version for the Spanish missile frigates (*Baleares* class). In this case the CWI was an adapted SPG-51C module, matching that of the ships' main SPG-51C antenna aft. As in the U.S. ships, the frigates had a second Mk 118 Mod 2 computer, and WDE Mk 1 Mod 7 modified to accept data from an SPS-52 radar rather than from the digital SPS-48 with which WDE Mk 1 Mod 7 was associated in U.S. service. The U.S. FFG 1 class had no comparable CWI in their gunfire-control radars because they had Mk 56 rather than Mk 68 GFCS.

SPG-53D was SPG-53A modified with CWI to control semi-active Standard surface-to-surface missiles, on board 5 *Knox*-class frigates (see Mk 68, below). This version used a standard

SPG-51D illuminator, with a Mk 152 computer and a Mk 72 Mod 6 signal data converter.

SPG-53E is SPG-53A converted to monopulse tracking, for better capability against sea-skimmers and also for quicker reaction. Conversions were scheduled to begin about 1977, but SPG-53F was used instead.

SPG-53F is SPG-53E with simulated ECM input for training. This version replaces SPG-53A on board many destroyers and cruisers.

These radars are manufactured by Western Electric.

◆ SPG-55

Band: C (track) and X (CWI)
Beam: 1.6 deg (C); 0.8 deg (X); 72 deg auxiliary beam (X)
Peak Power: 1 MW (C); 5 kW (CWI)
Gain: 39 dB (C); 47 dB (X-band)
Pulse Width: 26 and 1.5 microsec **PRF:** 203–225 pps
Antenna Dimensions: 175×218 in (total); dish 96 in
Antenna Weight: 12,970 lb (total radar assembly)

Pulse width and PRF refer to operation in C-band target acquisition-and-tracking mode. In the Mk 76 Mod 6 FCS, SPG-55B has a tracking module, using a high pulse-compression ratio. Pulse widths are 12.7 (compressed to 0.1) and 0.1 microsec, PRF is 427 pps. All versions of SPG-55B also have a CW doppler tracker mode, using a separate receiver (a 30-in Cassegrain parabolic flat plate with 34-dB gain and 3.0-deg beam). Scan rate is 1.67 rpm horizontal and 10 deg/sec vertical for both the tracking module and the CW tracker. There is also an auxiliary short-range mode for antimissile defense, using a Custer horn (12×3 -deg beam) to illuminate short-range low-altitude targets and, at the same time, provide a rear reference beam. The Custer horn is used in sector-scan engagements and continuous boat-track modes.

SPG-55 controls SM-1(ER) missiles as part of the Mk 76 FCS. Originally, it controlled both beam-riding and homing versions of the Terrier missile, but the beam-riding feature (consisting of a guidance transmitter and a beacon tracker) was disabled when the last nuclear Terriers (BT(N) version) were retired.

SPG-55 replaced the original Terrier guidance radar, SPQ-5, which could control only the beam-riding version of the missile. SPG-55 is a monopulse tracker using a Cassegrain antenna and a 4-horn cluster. It was designed to acquire a 1-m^2 target at Mach 2 with 5-G maneuverability, at up to 100,000 yd, 10 sec after designation (assumed accurate within 2 deg in bearing,

A pair of SPG-55 fire-control radars, with Harpoon canisters visible in the foreground. (U.S. Navy)

within 3 deg in elevation, within 1000 yd in range). It was required to track with an average angular error not exceeding 0.2 mils. There were 2 acquisition patterns: long range for ranges beyond 30,000 yd, covering $4 \times 6 \text{ deg} \times 2900 \text{ yd}$, programmed by Computer Mk 119; and short range (using the capture antenna system), scanning a conical ($10 \text{ deg} \times 2900 \text{ yd}$) volume.

Besides the anti-air mode, SPG-55 was designed with surface-target and shore-bombardment modes. In the surface-target mode, the FCS computer controls radar elevation; the radar tracks automatically in train, corrected for cross-roll. Optimum angle is maintained to minimize multipath.

SPG-55A was part of FCS Mk 76 Mod 1. It has now been superseded entirely by SPG-55B. Total weight was 45,000 lb.

SPG-55B was originally introduced as part of FCS Mk 76 Mod 2. Total weight is 50,000 lb. This version survives on board the *Mahan* class.

SPG-55C is the current version on board Italian *Vittorio Veneto*- and *Andrea Doria*-class missile cruisers, USS *Bainbridge*, and the *Leahy* class.

SPG-55D is the version on board the missile cruiser *Long Beach* and the *Belknap* class. It is presumably the NTU version.

SPG-55 has been considerably modified since its introduction. A special counter-countermeasures program began in 1964. The radar already used frequency diversity, and the Terrier missile it guided had a home-on-jam mode. In 1963 the *Worden* tested SPG-55B with frequency diversity, and the *Pratt* (DDG 44) tested SPG-55A's acquisition and tracking of a CW noise-modulated barrage jammer.

The new threat was a combination of deceptive ECM and new countermeasures techniques, which were expected to be particularly effective in a coordinated mass raid. For example, low-level attackers might appear at the same time missile boats fired their weapons, bombers laid a chaff corridor, a stand-off jammer appeared, and high-altitude missile bombers maneuvered in formation while practicing barrage and deception jamming. The situation might be further complicated by rain and land clutter, and also by the presence of friendly carrier aircraft. An integrated counter-countermeasures program for the 3T missile systems (*Tartar*, *Talos*, and *Terrier*) was announced in the fall of 1964. The *Halsey* (CG 23) tested control of the radar-ranging system in jamming; operator control in passive angle tracking (i.e., in tracking a jamming source); rapid reacquisition of targets with blinking jammers; and manual range tracking of a jamming target. The next step (1965) was Ordalts to improve SPG-55A's operation in clutter and chaff, followed by a near-term R&D program (1967). The short-term improvements were made on board the *King*, *Wainwright*, *Sterett*, and *Fox* in 1967. They consisted of a sidelobe canceler, 3 modes of passive angle tracking (PAT), preselection of beacon recognition (to track the rising missile), a new control panel (which made it easier for the operator to follow the new counter-countermeasure doctrine), and special ECM simulators for training.

SPG-55B replaced SPG-55A as part of the *Leahy* class's modernization program (Terrier FCS Turn-Around Program), which began in 1965. At the same time Computer Mk 119 Mod 0 was replaced by Mod 5. *Leahy* was the first ship modernized, in 1967-68, and the program included the earlier *Mahan* class (SPG-55B replaced SPQ-5). The modernization program included improved system reliability. It was common for the complex high-powered radar transmitter to fail, and transmitter repair could be lengthy. Ships were modified so that 2 antennas could share the surviving transmitter, in a "power sharing" mode. Switching could be automatic and instantaneous, so a ship would not lose a track or abort a missile in flight. This mode increased the availability of dual channels by 18%. Modernization also included a radar silence mode to defeat enemy countermeasures. For example, the CWI transmitter was turned on only when ordered to guide an HT missile; the beam-rider transmitter (now eliminated) was turned on only when a beam-riding missile was fired. The transmitter tubes were not turned off when silence was desired; they radiated instead into dummy loads. Similarly, the transmitters could be tested without ra-

diating, so a ship could maintain her capability without revealing her presence or capabilities to an enemy listener.

All of these programs were directed mainly against classical air attack. By 1968, however, naval interest had turned toward the threat of missile boats. The boats were small and difficult to detect, and their missiles could appear very rapidly. The initial response was SAMID (Ships Anti-Missile Integrated Defense), a program emphasizing the most complete use of all shipboard assets, including the search radars. A SAMID Immediate program was designed for FRAM II-, *Adams*-, and *Belknap*-class ships deploying to Vietnam. It combined improved passive detection, improved active detection by clutter suppression, and quicker reaction time by providing fire-control radars with horizon or sector-scan search capability, using special links between these radars and the ship's CDS.

Belknap (CG 28 and later)-class ships had their SPG-55B radars modified for horizon and sector search, both for additional search capability and for quicker designation from search to fire control. A new continuous boat-track mode (tracking a surface target) was introduced. The ship's NTDS program was modified. The test ship was the *Jouett*. Further SAMID improvements were a narrow-pulse mode (to avoid clutter), a new digital range and beacon tracker, and the Custer horn.

In heavy jamming, the radar can track a jammer (passive-angle-track [PAT] mode) and can accept external range data (e.g., from NTDS). Alternatively, the operator can manually track the target using a range-rate control (local-range-track mode), the FCS computer maintaining the range rate at the value last entered. There is also a "coast" mode in which tracking is abandoned, but values of range and range rate are estimated using prejamming figures. Current SPG-55s also have a CWAT (continuous wave angle tracking) mode in which the radar tracks in angle using its CWI; it cannot track in range because the signal is continuous. The advantage of CWI is its very high average power, which can be used to burn through a jammer (the narrow pulse is only equivalent to 0.3 kW of average power, the long pulse to about 5.8 kW).

These improvements were in addition to changes from vacuum tube to integrated circuit to high-speed digital technology, for much greater reliability. The current Mod 10 (from FCS 76 Mod 10) upgrade, which will be completed in 1993, is part of the NTU program. Presumably, that entails target acquisition and tracking at greater ranges.

SPG-55 and its upgrades have all been produced by UNISYS (formerly Sperry).

◆ SPG-60

Band: X **Beam:** $1.2 \times 1.2 \text{ deg}$ **Peak Power:** 5.5 kW
Pulse Width: 0.27, 1, or 6 microsec **PRF:** 25,000-35,000 pps
Gain: 41.5 dB **Antenna Dimensions:** diameter 160 in
Antenna Weight: 4015 lb total

SPG-60 is the pulse-doppler tracking-and-illuminating radar associated with the Mk 86 FCS; SPG-60 operates in conjunction with the SPQ-9 TWS search radar. The radar tracks using a 4-horn monopulse assembly, the CWI feed being mounted on front of the horns.

Typically SPG-60 acquires targets designated either by SPQ-9 or by a search radar, searching the designated area and then tracking at ranges of up to 50 nm. SPG-60 can illuminate targets for both Sea Sparrow and Standard missiles. An associated computer is used to vary pulse width and PRF, to resolve the range ambiguities inherent in pulse-doppler operation.

This radar is made by Lockheed Electronics.

SPG-60 elevation limits are $+85/-30 \text{ deg}$. The FOV of the associated television is continuously adjustable from 2.1 to 21 deg; output is a 729-line signal. Instrumented range is 100,000 yd; the radar can detect a 1-m^2 target at 85,000 yd. Maximum instrumented range rate is Mach 3. Range granularity is 5 yd. CWI: 5 kW injected, sufficient to engage a 1-m^2 Mach 2 target at 20,000 yd with a Standard Missile (SM-1 MR). Specified MTBF was 300 hr.

Two SPG-62 illuminators are visible above the after face of the SPY-1 radar on board the USS *Ticonderoga*, 1983. The large circular structure is the IFF associated with the Aegis system; above it are the TACAN (the flat radome at the masthead) and the LAMPS data link. (DoD)

◆ SPG-62

Band: X **Average Power:** 10 kW
Antenna Dimensions: diameter 90 in

SPG-62 is the illuminator associated with the SPY-1 (Aegis) radar and its Mk 99 MFCS. Unlike SPG-51, which SPG-62 resembles, it does not track its targets. The Aegis system points the illuminator at targets detected and tracked by the main radar, during the last few seconds of missile flight, to provide terminal guidance for the SM-2 missile.

SPG-63 was the alternative tracker-illuminator, using the same antenna, with C-band (42.5 kW, PRF 10,400–10,800 pps) tracking. SPG-63, however, was unnecessary: SPY-1 provided sufficiently accurate track data that SPG-62 could be slaved to it, with no tracking feedback.

◆ SPQ-9

Band: X **Beam:** 1.35×3 deg **Peak Power:** 1.2 kW
Gain: 37 dB **Pulse Width:** 0.3–16 microsec
PRF: 3000 pps **Scan Rate:** 60 rpm
Antenna Dimensions: 80.5×30 in (radome 120×96 in)
Antenna Weight: 1185 lb (including radome)

SPQ-9 is the surface-search and target-acquisition radar of GFCS Mk 86; this radar can also acquire and track low-flying aircraft. SPQ-9 is a TWS pulse-compression radar; the entire Mk 86 system reportedly can handle 120 tracks simultaneously. SPQ-9 was 1 of the earliest applications of optical pulse compression (16.4 microsec compressed to 0.12 sec, also given as 167:1 ratio). One source gives a peak power of 3 kW.

Maximum range is 20 nm, minimum 150 yd. There are 2 versions: 1 for surface search and very limited (2000 ft) air search, 1 for air search (with integral IFF) up to an elevation of 25 deg. Only the pure surface-search version is dome-enclosed. The operator can choose among 5 operating frequency ranges, using pulse-to-pulse frequency agility to defeat ECM. SPQ-9 is a digital radar, with digital MTI. The antenna is stabilized against roll and pitch.

Maximum instrumented range is 40,000 yd (PD 0.90 for a 1-m^2 target at 30,000 yd). Range resolution is less than 50 yd and range accuracy is $10 \text{ yd} \pm 0.025\%$ of range. In 1967 MTBF was given as 784 hr.

SPQ-9 radar without its radome. See also the illustration for the Mk 86 FCS. (Lockheed Electronics)

The alternative version, for combined air- and surface-search, had a 25-deg (elevation) fan beam and an IFF antenna and was generally mounted on deck. No production versions of this antenna appear to have entered service.

Current work is concentrated on an MTI/low-noise front end (LNFE). MTI should counteract chaff and heavy weather; LNFE should reduce the minimum radar cross section of a target to a quarter of the present value.

◆ VPS-2 (Sharpshooter Radar)

Band: X (9200–9250 MHz; 6 crystal-controlled frequencies)
Beam: 4-deg conical beam **Peak Power:** 1.4 kW (average 10 W)

Lockheed Electronics's coherent pulse-doppler MTI radar is used in the Spanish Meroka system. It is also used in U.S. Army Vulcan air-defense guns. In the Vulcan system, the radar is servoed to an optical line of sight. It searches automatically for the target for accurate tracking. Search range is 5000 m; the radar tracks targets moving at 15–310 m/sec.

◆ STIR

Separate Target Illumination Radar was designed for the Mk 92 FCS of the *Perry*-class frigates. STIR has no separate AN-series designation. Thanks to its greater diameter (i.e., higher gain), the STIR antenna can be used to track targets at ranges beyond those of the Mk 92 with which STIR operates. It also has a CWI to guide SM-1 (MR) missiles. Tracking is by monopulse, and in the CWI mode the antenna functions as a Cassegrain, the illumination being reflected off a subreflector at the monopulse cluster, and focused by the main dish. A CW fill-in horn is mounted in front of the monopulse cluster. The dish is pierced for 2 aligning telescopes and also for a coaxial television tracker (which, however, has not been fitted). Diameter is 100 in (turning radius 78 in), and height, including pedestal, is 138 in. This antenna is designated UD 417. UD 417 is substantially smaller than the Mk 39 antenna of SPG-60 (diameter 160 in), which is also a monopulse tracker with CWI and which is very similar in appearance.

STIR on board the USS *Rodney M. Davis*, 1987. (F. Jentsch)

◆ TAS (Target Acquisition System) Mk 23

Band: L **Beam:** 3.3×75 deg **Peak Power:** 200 kW
Gain: 21 dB **PRF:** See below **Scan Rate:** 15 or 30 rpm
Antenna Dimensions: 231×129 in (including pedestal)
Antenna Weight: 1950 lb topside, 10,000 lb total

The Hughes Target Acquisition System Mk 23 is the search radar and associated combat-control system with the Improved Point-Defense Missile System (NATO Sea Sparrow Missile System) in U.S. Navy service. The designation parallels that of Aegis, except that there is no separate designation for the search radar (analogous to SPY-1). The TAS radar is a range-gated pulse-

Hughes's Improved TAS three-dimensional radar. (Hughes)

doppler type, mounted back to back with an IFF antenna, and is intended to locate, acquire, track, classify, and designate missiles diving or popping up 30–60 sec before impact. The broad (vertical) fan beam covers missiles diving at steep angles, and the doppler processor can separate moving low-level targets from the surrounding clutter of the sea return. The beam is shaped so that most of its energy is transmitted at low elevation angles.

The waveform is ramped FM.

The radar automatically detects and tracks, feeding data into an associated combat-system computer. TAS is broadly equivalent to the British Type 967/968 associated with the Sea Wolf point-defense missile system. Mk 23 can track up to 54 targets simultaneously. The manufacturer claims that it can reject over 50 dB of clutter around a moving-target return. ECCM features include the ability to switch rapidly on and off (for EMCON, without risk of being unable to switch back on); and doppler processing helps TAS overcome jammers, both on and off axis. Range-gating makes it possible for a ship to concentrate on targets without accidentally tracking nearby friendly aircraft or surface ships (when, for example, an ASW ship is stationed between a carrier and a suspected-submarine contact). The operator selects a controlled-reaction zone, in which the radar picks up targets either automatically or semiautomatically, the latter method allowing the operator to override friendly or neutral tracks and so to prevent the system from engaging them.

The 2 primary operating modes are normal (automatic point defense, 20-nm scale) and medium-range (surveillance and air control beyond 90 nm). They can be mixed for combined point defense and air surveillance. PRFs corresponding to the 2 modes would be, respectively, about 4000 and about 900 pps. A PRF of 4000 corresponds to a first blind speed of about 1900 kt.

The radar antenna consists of 26 flared feed horns, plus 1 for sidelobe blanking and 1 for sidelobe cancellation. Total weight is 10,000 lb (2,000 lb topside). TAS radars are connected to general-purpose standard navy computers (UYK-20), which determine whether targets are threats (using IFF), rank them, and then designate weapons to engage. The computer can maintain more than 50 target tracks, each of which requires 20 words of the 60k memory. Reaction time is typically 60–80 sec, but the minimum is less than 30 sec. The operator uses a standard NTDS console (UYA-4).

Originally Mk 20 to 24 were developed, sophistication increasing with Mark number. Mk 24 incorporated an infrared sensor. Mk 23 was tested at sea on board the destroyer *Downes* in 1975. Mod 0 was the engineering-development model. Mod 1 is integrated with NTDS, for the *Spruance* class; Mod 2, for major auxiliaries, is a stand-alone model, with its own NTDS-type UYA-4 console.

In 1984 TAS was modified so that it could be connected directly to the SLQ-32 ESM warning system. TAS is currently being updated with UYK-44 computers, the associated memory being increased from 60k to 512k. The UYA-4 console is replaced by the new standard UYQ-21.

Hughes announced an updated version, MTAS (multimission TAS) in 1985, and a prototype has been in operation since 1986. The antenna consists of a 26×6 -dipole array controlled by diode phase shifters. It can produce either the sort of fat fan beam used by a conventional TAS or a fat elevating lobe beam as in a conventional electronically scanned antenna (such as SPS-52). However, because the array is phase-phase controlled, the beam can be moved electronically in both elevation and in azimuth. Normally a target would be detected in the 2D fan-beam mode. At shorter range the radar would shift to 3D operation to obtain target elevation. The elevating beam is fat because it is essential to obtain full coverage at short range and at very steep angles; pencil beams do not provide enough "paints" of the target to give a high probability of detection at short range. Phase-phase steering is necessary to allow the radar to return very quickly to a target detected in 2D mode, before the antenna has turned completely away.

The combination of normal 2D operation with 3D operation only as required explains Hughes's description of the radar as "2½D." Hughes also calls MTAS a "4D target designation radar" (bearing, range, elevation angle, and range rate).

As of early 1989, the conversion of a TAS system to improved TAS is a U.S. Navy-approved ORDALT, which can be carried out at pierside in 10 days. Conversion entails installation of the new antenna, reprogramming of the displays, and insertion of some new electronic cards in the equipment cabinets. No such conversions have, however, been carried out. When MTAS was first announced in the spring of 1985, Hughes expected its incorporation in the sixtieth TAS to be delivered (1987).

Hughes has offered a version of the improved TAS radar as the MFR of the NAAWS program. Instead of elevating the entire beam, this version would maintain a fixed lower lobe pointed at the horizon, the same radar antenna simultaneously conducting horizon and hemisphere searches.

Hughes also offers a small-ship version of TAS, with a smaller transmitter and antenna, at a total weight of 6000 lb (compared to 10,000 for the basic TAS).

The FY86 program included a new requirement to integrate the SAR-8 IR search-and-track device (IRSTD) with Mk 23 and SLQ-32 via the Mk 23 computer. IR-to-radar and IR-to-ESM track associations will be used to complement the radar-to-ESM association already being developed. The Mk 23 integration will permit a demonstration of IR designation to NATO Sea Sparrow in support of SAR-8 tests. The NATO Sea Sparrow office is currently trying to fit the fully integrated TAS/SLQ-32/SAR-8 system into Sea Sparrow ships; this system can also designate targets to the RAM missile. The result is a relatively inexpensive system with impressive track-handling capability, which some in the office have called "Polish Aegis." The system includes a Hughes-designed TEWA (threat evaluation and weapons assignment) component, which decides whether a given threat should be engaged by hard- or soft-kill systems, and, if hard-kill, by RAM or Sea Sparrow.

As of early 1989, the NATO Sea Sparrow office had just given permission to integrate a Hughes FLIR and a Ball Aerospace LLLTV into the overall system. The FLIR, originally developed for the Abrams tank, is the nonradar tracker of the system. The Ball LLLTV is installed atop the Mk 91 director. One problem in this installation was that director slew was too coarse for the LLLTV, with its very narrow FOV; Ball had to dampen director motion to keep the LLLTV on target. These electro-optical sensors will both be integrated with the TAS, to increase detection

TAS Mk 23 antenna. (Hughes)

TAS Mk 23 on board the carrier *Ranger*, July 1986. It is the bar antenna on the mast, above the large flat plate of SPS-48C. The radar on the after side of the mast, just below it, is SPN-43, a short-range air-search set for carrier air control. (Hughes)

UYA-4 display of the TAS Mk 23 system, on board the carrier *Ranger*, July 1986. The display consists entirely of processed rather than raw video. (Hughes)

range, particularly when long radar range operation is precluded. SAR-8 is likely to be a future feature of this system.

Current versions of TAS Mk 23 are:

Mod 0 Original version, with a Mk 158 computer.

Mod 1 UYK-20 computer and OJ-451(V)9/UYQ-21 display; this version could control up to 3 NATO Sea Sparrow launchers.

Mod 2 UYK-20 computer and OJ-194(V)3/UYA-4 display for non-NTDS ships (production version of Mod 0).

Mod 3 UYK-20 computer and OJ-451(V)9/UYQ-21 display (modified Mod 1).

Mod 4 UYK-20 computer and OJ-451(V)9/UYQ-21 display (modified Mod 2).

Mod 5 As Mod 1 but UYK-44 computer (for *Spruance* class).

Mod 6 As Mod 2 but UYK-44 computer.

Mod 7 As Mod 1 but UYK-44 computer.

Mod 8 As Mod 2 but UYK-44 computer and new OJ-451/UYQ-21 display.

As of the spring of 1990, the improved version of TAS is known as TASI, and its future is tied to that of the NAAWS program. Although the radar is thoroughly tested and suited to pier-side installation (with some new cards to be installed in the below-decks electronics cabinets), the expected installations did not materialize. An ORDALT for conversion was approved, but the necessary funds went to NAAWS instead. Now it seems likely that existing TAS radars will slowly be converted. It is possible that TAS will figure in the version of NAAWS finally selected.

◆ R76/HR76

Band: X (12 preselected frequencies over 800 MHz)
Beam: 2.7 deg **Peak Power:** 250 kW
Gain: 32 dB **Pulse Width:** 0.25, 0.5, or 1 microsec
PRF: 1000–3000 pps **Antenna Dimensions:** 1 m
Antenna Weight: 205 kg (1200 kg total; 360 kg including TV)

RCA's small-ship fire-control radar uses distributed microcomputers connected by a data bus rather than the usual central computer. Their functions include target tracking, operator console interface, and ballistic computation. RCA argued that such a distributed system was relatively easy to update, since changes in any function would tend not to disturb programs running in another computer, and also since additional functions generally required their own microcomputers. A typical installation included as many as 8 microcomputers: 1 for track radar, 1 for the track console, 1 for gunfire control, 1 for the search console, 1 for data extraction, 1 for the ship interface (to other sensors and weapons), 1 for bus control, and 1 to control EAROM (electronically alterable ROM, in which constants such as magazine temperature are entered manually). The 16-bit bus operates at a 100-Hz frame rate. The data bus design is such that the system can, at least in theory, be extended into a fully integrated tactical data system, although in fact that has not been done by any user.

R76 was originally offered with a single system computer, a 16-bit 32-kword UYK-28. By 1984 the system was provided with 2 types of microcomputers, an RCA control processor (RCP) (a floating-point Mil-Std-1750A machine) and a Rolm 1664 (in effect a UYK-19 with hardware floating-point arithmetic, a superserset of UYK-19). The system uses 16 microprocessors on a common bus with ROMs, each on a separate printed circuit module in a drawer, for redundancy. One processor is used for mode control, 1 for target range, 1 for target angle, etc. The system bus as a whole could accommodate up to 64 microcomputers, far more than the system was ever likely to need.

Early in 1982 the Royal New Zealand Navy selected R76C5 for frigate modernization because its basic technology was more modern than those of alternative systems (Ferranti WSA 400, Marconi ST802, Philips 9LV200, and Signaal WM20-series). The first contract was signed in June 1982, and the first installation began in February 1985 (HMNZS *Wellington*). HR-76 is the fire-control tracking radar of the Taiwan navy's *Wu Jinn I*-type destroyers. (See also the description of the H930 Mod 1 tactical command/control system in the Surveillance and Control section.) Some examples of this version have also been installed in coastal defenses.

The antenna is gyro-stabilized for horizon search. It is a par-

abolic reflector with a 4-horn Cassegrain feed for monopulse tracking. The mount also carries an electro-optical contrast tracker (TV or IR), and a separate electro-optical director carries a tracker with a laser range-finder and a remote-control zoom lens (with an FOV variable from 30 to 1.5 deg). Acquisition range on a 1-m² target is 40 km [43,700 yd], and accuracy at 20 km is 10 m in range and 1 mrad in bearing/elevation. Search-scan period is 4 sec (15 rpm), and reaction time from designation to tracking averages 3.5 sec. To track a target less than half a beamwidth above the horizon, the antenna is held at a fixed elevation, and the target is tracked off-axis.

R76 could be adapted to track an airplane or a helicopter while receiving down-linked data from a coded beacon, for OTH missile targeting.

The display is a 16-in PPI showing synthetic and raw video.

RCA offered a variety of versions: the basic R76, R76C for large patrol boats and destroyers, R76M for guided-missile ships, R76D to control drones and RPVs, R76LB for land-based guns for coast defense, and R76P for small patrol craft. At least in some versions, R76C uses a radome-enclosed antenna and has a higher-power transmitter. R76M uses the same components but has a 2-operator console, the second position for missile control. Missiles are guided by modulating the tracking beam, the missile being tracked by the second channel of the 2-channel monopulse receiver. R76D has a 2-operator console (1 operator for drone control), and the 2-channel receiver and coding capability of the transmitter are used for drone operation. Maximum instrumented range is 160 km, to track a beacon-equipped drone or RPV. R76LB has an instrumented range of 80 km, to take advantage of the greater horizon range of a cliff-mounted radar.

HR76 was derived from RCA range-instrumentation radars and airborne satellite-tracking antennas.

◆ W-120/W-1200

Westinghouse's private-venture shipboard fire-control radar is based on the APQ-120 of the F-4J. Target acquisition is by automatic search either around an externally provided target position or around the last known target position (if track is broken). Typically a 4000-yd acquisition window is placed around the designated range. The radar acquires a target in 20 msec after designation. If automatic track is lost, the radar attempts to reacquire the target. There is also a mode for detecting low fliers. Peak power is 165 kW (pulse widths 0.4 and 2.0 microsec, PRFs 1000 and 500 pps). Westinghouse claims that W-120 can detect a 1-m² target at 30 nm; that range accuracy is 0.01% to 2.5 nm, then 2% at greater ranges; and that angular accuracy is better than 2 mrad. The antenna is a radome-enclosed 32-in paraboloid (gain 34.5 dB) that can elevate/depress to +90/–30 deg. Beamwidth is 2.8 deg. Search patterns are 10-deg azimuth × 30-deg elevation scan; 10 × 15 deg scan; spotlight or fixed beam position. Reliability: 300 hr MTBF. The antenna/pedestal assembly weighs 860 lb, and the display/controls 100 lb.

Westinghouse offered several optional features: CW guidance for Sea Sparrow; 250-kW peak power; MTI/MTT (moving-target track) noncoherent mode (which was particularly useful against low fliers and could be entered automatically whenever the space-stabilized elevation angle fell below a preset angle of about 2.5 deg; this mode improved signal-to-clutter ratio by about 20 dB); and a new slotted planar-array antenna (lower sidelobes).

W-1200 was a series of modular FCSs developed by Westinghouse to compete with the H930 series; the associated tracker was W-120. W-1200 itself had no tracker; it was broadly equivalent to EX-93 (see that entry). W-1200 employed an optical director, an LN-66HP radar, a UYK-19 computer, and a Westinghouse UPA-62 display. It could control 35- and 40-mm guns. W-1200 seemed to have been the only one in the series sold (to South Korea for the *Paek Ku* class). W-120 was sold as part of the H930 system for Korea and Taiwan. W-160, announced in 1982, is the successor to W-120 in these systems.

◆ W-160

Westinghouse's private-venture shipboard fire-control radar is based on the APG-66 fire-control radar of the F-16 fighter. The X-band pulse-doppler radar, using a 42-in reflector (effective aperture 36 in; gain 36 db) has a range of 25 nm on a 1-m² target, claimed MTBF being 600 hr (30 min). Tracking is by monopulse (6-, rather than the usual 4-, horn feed for greater countermeasures resistance). Tracking accuracy is better than 1 mrad in angle and 15 m in range. An alternative 6-ft antenna (42-db gain) extends range to 46 nm. A digital computer takes angular data from the radar and computes a target's position in 3D. The computer controls the antenna both for search and for tracking and is powerful enough to calculate gun ballistics, making the system self-contained. The radar is compatible with guns of up to 5-in caliber and with NATO Sea Sparrow and SM-1 missiles.

Radar characteristics: peak power is 16 kW; pulse width is 1 or 10 microsec; PRF can be 1 of 8 between 1000 and 14,200 pps; beamwidth is 2.5 deg (1.25 deg with 6-ft antenna). The transmitter is coherent, so it is suited to moving-target indication (MTI), using an FFT to extract the frequency characteristics of the returned echo. That ability is important both for tracking and for clutter/jamming rejection. The radar can operate in either a search mode (low elevation, 360 deg at 15 rpm) or in its primary tracking mode. At low elevation angles, off-bore-sight tracking is used to avoid multipath propagation (mirror images off the sea).

W-160 has 9 search modes (5 surface search, 4 air search) and 6 track modes (2 surface and 4 air). It detects sea-skimmers on the horizon by its good subclutter visibility. Six special sub-modes offer missile-launch detection, projectile spotting, and kill assessment. Instrumented range is 75 km. The airborne origin of the system shows in its light weight (750 kg) and its limited power consumption (13 kW). The associated computer has 16 kwords of RAM and 48k of ultraviolet EPROM, using 16-bit words.

W-160 is the fire-control tracking radar of the Taiwanese navy's *Wu Jinn III*-type destroyers. (See also the description of the H930 MCS tactical command/control system in the Surveillance and Control section.)

Chien Yang is fitted with an H930 modular combat system. She is fitted with a Signaal air-search radar, SPS-10/SPS-58, for surface and low-altitude air search, and a Signaal STIR fire-control radar, which also provides illumination for her SM-1 surface-to-air missiles. The masthead radome is a TACAN. (F. S. Mei)

The W-160 "golf ball" on board the Taiwanese destroyer *Chien Yang*, a *Gearing* subject to WS-III modernization. The box at the base of the mainmast is 1 of 2 Chang Feng III (Hughes MEWS) arrays; note the chaff launchers atop the deckhouse, forward of the array. The radome at the top of the mainmast, not entirely visible here, is probably the Argos 680. The boxes hold SM-1 missiles. (F. S. Mei)

RADAR INTEGRATION

◆ Aegis

Aegis is the overall weapons system (Weapons System Mk 7) that uses a SPY-1 radar to control SM-2 anti-aircraft missiles. Mod 2 was planned for the abortive U.S. strike cruiser (CSGN). Mod 3 equips *Ticonderoga*-class missile cruisers. Baselines: (1) *Ticonderoga*; (2) CG 52-58, with the vertical launching system, Tomahawk, and ASW upgrades; (3) CG 59-64, with SPY-1B and UYQ-21 consoles; (4) CG 65-73, with UYK-43/44 computers and increased battle-group capacity in the Aegis display system. The *Arleigh Burke* (DDG 51) combat system is a combination of (2) and (3); baseline 4 builds on DDG 51 and introduces the UYK-43/44 computers. The baseline-2 program was demonstrated at the Aegis land test site in FY86, and the ASW upgrade was added to the program in September 1986.

The Aegis display system. (RCA)

Aegis large-screen decision displays. (RCA)

Aegis large-screen displays on board the cruiser *Vincennes*. They are paired: 1 set for the embarked group commander, 1 for the ship's CO or TAO. In this case the pair of screens shows the same scene (the southwestern coast of the United States) in 2 different scales. The *Arleigh Burke*-class destroyer, which is not designed to carry an embarked group commander, has only 1 pair of screens. (Hughes)

Tomahawk was integrated into baseline 2 in FY87. Baseline 3 was demonstrated in June 1987. Baseline-4 integration and demonstration were scheduled for March 1988 through February 1989 (as of January 1987).

Aegis replaces the NTDS/WDS combination of earlier U.S. missile cruisers. Aegis is built around Command and Decision System Mk 1, Aegis Display System Mk 1, and Weapons Control System Mk 1, the first and last replacing, respectively, NTDS and a WDS (the original Aegis test ship, *USS Norton Sound*, had WDS Mk 12). All of these systems are built around UYK-7 computers. In the Mod 3 version, Aegis employs 16 UYK-7s, 11 UYK-20 minicomputers, and 1 UYK-19 computer.

The display system has 4 very large (42 × 42 in) paired screens and is entirely new. In principle, 1 pair of screens is for the ship's captain and 1 for the embarked group commander. Each pair of large screens is supported by 2 command-display consoles, a data-input console, and 5 automated status boards (ASTABs). In addition, 2 ASTABs are on the bridge.

The large screens display processed, rather than raw, radar video as tracks, NTDS symbols, and Aegis symbols, in white

on a blue background. Each screen can operate individually, at its own range scale; and controls allow for irrelevant tracks to be suppressed, for tracks to be tagged (track numbers or alphanumeric labels of up to 24 characters in 3 lines), and for offsets from a display centered on the ship. Additional information is supplied on the associated command-display consoles and the ASTABs above the large screens. In principle, the commanding officer and TAO sit at the 2 command-display consoles, with a data-input assistant at the adjacent input console.

Because the 2 displays of either group can show the same situation at radically different scales (calling up the same computer data base), operators can position their ball tabs on either large-scale display (LSD), and operators working to different

scales or in different warfare areas can share the same target data without changing screens or even manually pointing (as in standard NTDS systems). Important tracks and symbols can be highlighted without being tagged.

The display system can also store up to 40 patterns, such as formation diagrams, anchorages, and amphibious boat lanes. It can automatically initiate up to 16 simultaneous track histories until ordered to stop doing so. It can also provide digital maps of the area in which the ship is operating, refreshing own-ship position every 2½ sec.

Aegis as a whole is credited with the ability to handle 128 tracks. The SPY-1 radar can actually handle more, the extra capacity being used to avoid overflow. The most important limit on track capacity is the interface with the track file in the associated command/control system. The margin in the radar prevents overflow when numerous long-range tracks of little immediate interest are present.

The Aegis display system is to be the basis of a future battle-group AAW display group, which will allow an embarked battle-group AAW commander to control the force.

Versions (Aegis baselines):

Baseline 1 CG 47-51: original version

Baseline 2 CG 52-58: Vertical Launching System, Tomahawk, ASW upgrades

Baseline 3 CG 59-64: SPY-1B, UYQ-21 displays

Baseline 4 CG 65-73: version that converts computer programs to UYK-43/44 computers and provides increased battle-group capability in the Aegis display system. This version includes a special UYK-43 version of the Mk 86 FCS.

The FY90 program included integration of the SPS-49(V)7 air-search radar, the Mk 86 Air Gun Mode, and Ship Signal Exploitation System (SSES) upgrades into the Aegis combat system.

Work is currently proceeding on an expanded display system, under the Command Support At-Sea Experiment. It includes both color graphics and an auxiliary screen that can be used to preview large-screen displays, or to show such auxiliary information as the *altitude* track history of a designated target (presumably a capability required after the *Vincennes* incident). This experiment is described in greater detail in the Surveillance and Control section.

The FY91 program includes upgrades (both hardware and software) for increased capability against sea-skimming missiles, to enter service on board an FY94 missile destroyer.

◆ BGAAWC

Battle-Group AAW Coordination is a program to tie together all the ships of a battle group. Aegis data will ultimately be disseminated throughout the group so that non-Aegis ships will be able to use that information for firing. That dissemination requires both more efficient use of existing sensors and better gridlock within a force, since without good gridlock ships cannot use one another's data. By 1986 an SPS-48 detection data converter had been tested and deployed. A surface-gridlock system was installed on board the *Ticonderoga* class, solving a 20-yr-old problem. An airborne-gridlock system was under test on board an E-2C. Air gridlock was demonstrated in the *Vinson* battle group, and Aegis autogridlock technology was transferred to non-Aegis ships. These efforts together constituted Phase I of the BGAAWC program.

Phase II concerns force-control items to place weapons on target, e.g., improved gridlock using the GPS satellites and improved Aegis displays.

Phase III initiates cooperative engagement capability, in which CDS (Aegis command) fire-control-quality data are exchanged, and missiles are remotely fired. This capability has already been demonstrated by an Aegis ship and a Terrier ship; the next stage is the remote firing of an SM-2 Block II missile on board a vertical launcher ship, by another Aegis ship, against a real target.

The effect of BGAAWC is to increase the efficacy of fleet air defense substantially, since non-Aegis (even non-AAW) ships can become, in effect, spare magazines for Aegis ships, which can order launches and control the missiles in terminal engagements. That capability in turn is possible because SM-2 is fired into a preset basket and only intermittently command-guided.

Aegis's use for remote missile operation is of 2 types: remote track launch on search (RTLOS) and, at a more primitive level, transmission of Aegis data by Link 11 to designate a target to a fire-control radar. In RTLOS, a missile is launched by a ship that is not emitting at all, the Aegis ship carrying out the entire fire-control function. The firing ship, then, can be (in effect) in ambush, since an oncoming airplane may well be unaware that it is within attack range. In theory, RTLOS could be extended to include control (or at least designation) from an airborne platform.

RTLOS was first tested in the summer of 1985, using the missile ships *Mahan*, *Yorktown*, and *Richmond K. Turner*, and 2 BQM-34 drones. *Yorktown*, an Aegis ship, tracked both drones with her SPY-1. Track data were turned over to 1 of the other ships, which used her own SPG-55 for the final engagement with an SM-2 missile. Early in 1986 RTLOS was conducted using an Aegis ship, an E-2 airplane, and an NTU ship.

◆ New Threat Upgrade (NTU)

NTU is an AAW upgrade for U.S. missile cruisers and *Kidd*-class destroyers. Existing air-search radars are replaced by SPS-48E and SPS-49(V)2, and a new SYS-2 IADT feeds NTDS, which in turn feeds a new WDS Mk 14. The existing SM-1 missile system is replaced by the autopilot-controlled SM-2 Block II. That replacement makes for greater range because of the option of flying missiles along the most efficient possible paths. Another reason is that each missile can home on a more distant target. SM-1 must receive substantial illumination energy virtually at the time of launch; indeed, missiles are designed to self-destruct if they do not receive the reflected illumination within a few seconds of takeoff. Because reflected energy at the launcher falls off as the fourth power of range, every increase in range is extremely expensive. If, however, the missile can approach close to its target before having to pick up much reflected energy, then effective range depends on the level of energy at the target, not at the launcher, and that energy falls off only as the square of the range. Finally, because the SM-2 autopilot can be programmed in flight, missiles can be guided into appropriate homing baskets even near maneuvering targets. The result is not quite Aegis—without SPY-1 accuracy the SM-2s cannot be guided very close to their targets before requiring illumination—but is far better than earlier SM-1 systems, in increasing range and allowing multiple engagements. Because SM-2(ER) is the longest range SM-2, NTU is particularly valuable when applied to extended-range ships (formerly Terrier ships). SM-2(ER) will become less important only when the boosted version of SM-2 Block IV enters service.

In the NTU system, the ship tracks the target only, transmitting the target's position to the missile. The missile computes the trajectory required to hit the target. In contrast, Aegis, which has a more precise tracking radar, tracks both missile and target, commanding the missile into position.

In Tartar ships, NTU uses CW acquisition and tracking to improve performance against high altitude, supersonic, steeply diving missiles.

As of March 1987, the U.S. Navy planned to upgrade 31 ships (9 nuclear cruisers, 9 *Belknap* class, 9 *Leahy* class, and 4 *Kidd* class) in FY85-93. However, this program may be reduced because of budgetary problems.

Work on CG/SM-2 and NTU for extended-range ships began in FY86, for the *Belknap*- and *Leahy*-class conventional cruisers; the nuclear cruisers *Long Beach*, *Bainbridge*, and *Truxtun*; and the *Mahan*-class destroyers. The *Mahan* was the test ship. The *Bainbridge*, *Truxtun*, and the *Mahan* class were dropped from the program, as they are to decommission in the early 1990s. The first NTU (ER) ship was the USS *Biddle* (1987). The

Tartar (or MR) version of NTU is to be applied to the *California*- and *Virginia*-class nuclear cruisers and to the *Kidd*-class destroyers; the prototype is the USS *Scott* (DDG 995).

◆ RAIDS

Rapid Anti-Ship Missile Integrated Defense System is a near-term improvement to the *Spruance* class. The project was begun by NSWC early in FY88 in response to fleet requests (i.e., presumably in response to experience in the Persian Gulf, including the *Stark* incident). The problem in the case of the *Stark* seems to have been excessive false alarms, which tended to reduce alertness when the attack actually developed. Nor was it clear that an unusual signal, which turned out to be that of an Agave attack radar, was properly interpreted. Reactions were just too slow, and there was no useful guide to the sort of integrated maneuver and chaff-launching reaction that was needed. Appropriate maneuvers depend on too many variables to be extemporized.

As of early 1990, a demonstration was scheduled for October 1990. RAIDS was formally established as an acquisition program in FY89. This very rapid development required that RAIDS use existing equipment; it is essentially a better means of exploiting the sort of information already available to the ship, to control on-board weapons. Software was developed using 386-based laboratory computers, and rapid development requires that the shipboard hardware use the same Intel 80386 chips.

The Phase 1 system generates tactical recommendations (e.g., turn to course 295, fire chaff) based on an automated evaluation of the tactical situation. The current NTDS installation drives hard-kill weapons, such as the NATO Sea Sparrow and the 5-in guns, in a reasonably timely fashion, but there is no corresponding automated control of ESM and decoys. Nor is there any system that recommends the maneuvers appropriate to (or necessary for) the use of the decoys, e.g., to minimize a ship's radar cross section in the direction of the threat missile. No such system can be fully automated because no officer will surrender maneuver control to a computer. That is why RAIDS is a recommendation system. It carries threats designated to hard-kill weapons as constraints on its tactics (e.g., the ship cannot be turned to mask a hard-kill weapon). It displays hard-kill engagement envelopes.

A further Phase 2 includes automated reactions, both by countermeasures and by antiship missile defense (ASMD) weapons. Additional sensors will be added. As of early 1990, Phase 1 is to be introduced into the fleet beginning in FY93. Phase 2 is a preplanned product improvement, applicable to frigates and to other classes, as well as to the *Spruances*.

RAIDS has 2 elements. One is the integration of ESM information and other ship sensors in what amounts to a new combat data system. The other is the automation of tactical recommendations, using a software "tactics engine."

Currently, NTDS ties together the ship's main active sensors but does not really embrace the passive ones. In a *Spruance*, the existing SLQ-32(V)2 and the ULQ-16 pulse analyzer are individual stand-alone devices. The EW officer maintains a status board and reports orally to the CO and to the TA in CIC. EW data are analyzed manually, using classified publications listing emitters. This procedure cannot possibly keep up with an approaching missile; it is designed, presumably, to deal with submarine emissions and also with the requirements of long-range missile targeting, neither of which is likely to be very time-urgent. RAIDS ties the SLQ-32 and the ULQ-16 together by means of a dedicated digital bus to reduce the operator's problems in resolving identification ambiguities. The new EWS (EW supervisor) console provided by RAIDS shows a filtered NTDS threat picture overlaid on the emitter picture, making for easier interpretation of the latter.

RAIDS has 3 elements: the sensors providing the ASMD picture, the sensors used primarily to determine whether soft kill succeeds, and the display/analysis element. All are connected by a data bus (an LAN). The ASMD sensors are NTDS (CDS) itself (i.e., the main search radars and off-board data provided

via Link 11), SLQ-32/ULQ-16, and the radars of the 2 Phalanx guns. The main soft-kill evaluation sensors are the Mk 86 FCS radars and the Mk 23 TAS. Presumably, the latter are used because they are needed to initiate the alternative hard-kill measures. All of the sensors are connected to the system via RAIDS interface units (RIUs) incorporating 386 chips. CDS and SLQ-32/ULQ-16 share a common RIU via a T-bar switch; Mk 86 and Mk 23 share a common RIU. The 2 Phalanx each have their own RIU.

The main computing element is a track manager, based on 386 chips. It is responsible for reducing the high false-alarm rate that has plagued earlier automated ASMD systems. RAIDS avoids the problem by associating radar tracks formed in the ship's NTDS with particular emitters, using both factors (range/range rate in NTDS and emitter character) to decide which tracks merit reaction. If a missile seeker is not detected, RAIDS guesses the most likely platform and provides a synthetic missile track with estimated impact time. Threats are ranked according to which is likely to hit first. The ship's officers can insert the weights they consider appropriate (depending, e.g., on where the ship is operating). The SLQ-32 can be preset to report radars of particular interest.

The RAIDS displays are located next to the SWC (surface warfare coordinator)/TAO console in CIC, next to the SLQ-32 console in CIC, and near the centerline pelorus on the bridge (i.e., convenient to the OOD ordering evasive maneuvers). Each display is a color CRT showing a threat evaluation (in PPI form), recommended actions, and a timeline showing just how urgent those actions are.

Maneuver recommendations are based on factors such as wind, chaff-cloud size and development time, ship cross section (on a given bearing), and sensor and weapon blind arcs.

◆ RVP/SIDS

Radar-video processors are used to provide existing radars with an ADT capability. One such system, the Hughes CV-2834/UYA-4(V), was applied to the DDG 2 combat system about 1972 at the NTDS Development and Evaluation Site, Mare Island, as part of a projected DDG 2-class NTDS installation. This system was not applied to U.S. *Adams*-class destroyers, but it was installed on board the 3 Australian ships of this class. Trials were conducted between June and July 1975 on board HMAS *Perth*. The system was extended to the SPS-52 3D radar, and fully automatic control and surface tracking was added in 1976. In this system, radar-video processing could be applied to 1 radar (SPS-10, -40, or -52) at a time.

Initially (1974-75) the main mode of operation was manual track initiation, followed by automatic tracking; and there was no surface-tracking mode. The RAN asked for fully automatic tracking, the CV-2834 program being modified for ATD (with manual override). After these modifications, the radar operator's task was reduced to choosing a radar, setting the optimum video level, and then turning on the RVP autocontrol; the operator would then monitor RVP performance. By 1981 the Australians typically operated their RVP in automatic control 90% of the time, finding that tracking was much better than earlier manual methods, with excellent target resolution at long range, and (because the system does not lose alertness as its operator tires) with a sevenfold improvement in probability of detection for a given opportunity. Reaction time is dramatically reduced: the estimated range at which a Mach-2 target must be detected to provide enough reaction time so that the target can be killed before passing inside minimum missile range is about half that required by the original system in totally manual mode.

In the *Perth* system, ADT data are checked by a tracking program, to see whether they correspond to realistic target motion, and those that are evaluated as real are retained in a target track file. In exercises about 1980 HMAS *Perth* was able to exercise primary tracking responsibility for a force whose other members were all non-ADT NTDS ships. One result of the success of the *Perth* system was that the RAN specified RVP/ADT for its *Perry*-class frigates. The German *Adams*-class (*Lutjens*-

class) missile destroyers have been fitted with SYS-1, as have 3 U.S. *Adams*-class destroyers.

SYS-1 and -2 differ from the *Perth* system by fusing data from all the shipboard radars; there is no operator selection of which radar to use.

The Sensor Interface Data System (SIDS) uses a CV-2834 and a computer to provide an existing radar with ADT, providing track data to the shipboard command/control system as would a manual operator. It is driven by a UYK-20 computer fed by raw data from an SPS-49 or -55; it services command/control either directly (as in FFG 7) or through a sensor synthesizer called SIDS (CGN 9 and CG 26 class). The RVP/UYK-20 combination is also incorporated in the Hughes TAS Mk 23.

◆ SYS-1/2

The Integrated Automatic Detection-and-Tracking (IADT) System is intended to integrate the disparate radars on board a missile destroyer into a single system. Video inputs (contacts) from the individual radars (SPS-65, SPS-40, SPS-52C) are correlated to form unduplicated tracks, the computer tracking the apparent centroid of an array of blips associated with a single target.

Each radar is fitted with a radar-video converter (RVC). The raw radar video is passed through a video processor consisting of an integrator, an automatic detector, and a data extractor. The integrator sums echoes from a single target. The automatic detector estimates background clutter and noise and compares them with this sum, deciding that a target is present when a set threshold ratio (intended to hold the false-alarm rate to a preset value) is exceeded. That comparison suppresses much of the surrounding clutter. The associated data extractor computes the associated target's range and bearing and puts these data into a form appropriate to the TWS computer, which correlates these data with existing tracks.

This technique can be used to refine the target's position on a beam-to-beam basis, in 3D. The SPS-52C radar carries out this refinement internally, in its video extractor and control group. Conversely, false targets can be rejected when they fail to reappear on a beam-to-beam basis. The system can also adjust its detection criterion depending on circumstances; for example, the system can increase detection probability in a high-threat area by accepting a higher rate of false alarms.

SYS-1, which uses 2 UYK-20 computers, supports 2 NTDS-type (OJ-194(V)3/UYA-4) consoles, whose operators include the radar-control (RC) and detector-tracker-monitor (DTM) operator. Track symbols and vectors are shown on the PPI together with a track-history display (THD) on tracks requested by the operator. The THD is a time-compressed display of about 1 min of track history. There is also a digital display of track data, radar environment parameters, and program status. Both consoles are driven by 1 of the SYS-1 computers, the other serving as a backup.

SYS-1 block diagram. (Norden)

The single-target tracks are transmitted directly to the tactical data system (TDS), a specialized destroyer system in missile destroyers upgraded with SYS-1, and NTDS in the case of cruisers fitted with SYS-2. The TDS operators decide which tracks the system supplies to the WDS, which in turn assigns guns and missiles to the targets. There is an alternative quick-reaction mode in which the SYS system passes its data directly to the WDS, to respond quickly to short-range and pop-up attackers. In the late 1970s it was claimed that SYS-1 more than halved reaction time.

SYS-1 may function either as an ADT or as an IADT system. In a *C. F. Adams*-class destroyer, SYS-1 integrates data from SPS-52C and SPS-40C/D; SYS-1 has provision for later integration with SPS-67 with AM. The integrated tracks flow into the DDG-TDS command/control system, which also receives IFF and sonar data. SLQ-32(V)2 data are entered by keyset, and the system also receives data links (Link 11 and Link 14). The system, in turn, provides data to the weapons systems and their specialized computers.

SYS-1 was designed specifically for DDG 2-class missile destroyers, using SPS-40 and SPS-52C radars as its primary sensors. Land tests began in October 1977, and these systems were then tested successfully on board the missile destroyer *Towers* in December 1977–September 1978. This program was part of the *Adams*-class modernization. Only 3 ships were fitted: the *Tatnall*, *Goldsborough*, and *Benjamin Stoddert*, the first at Philadelphia (August 1981–November 1982), and the other 2 at Pearl Harbor (April 1983–July 1984 and April 1984–August 1985).

SYS-2 is an IADT designed for CG/CGN/DDG 993. It integrates the SPS-48E and SPS-49(V)5 radars instead of SPS-52C and SPS-40, and interfaces with an NTDS computer instead of with DDG-TDS, and with WDS Mk 14 rather than Mk 13. SYS-2 incorporates a Kalman tracker and is being installed as part of the New Threat Upgrade (see above).

SYS-2(V)2 is the IADT for the *Perry*-class frigates. SYS-2(V)3 is the IADT of the *Wasp* (LHD 1) class.

SYS-3 is a system procured for the Israeli *Sa'ar-V* class under the U.S. assistance program.

SYS systems are currently in service in the U.S., Australian, Italian, and German navies. Norden is currently developing a next-generation system, IRDIS (Integrated Radar Detection and Identification), for an unnamed foreign customer's corvettes (presumably the new Israeli *Sa'ar-V* class now being built in the United States). IRDIS will automatically integrate nonradar data, such as ESM data, with the radar-generated track files. IRDIS-type systems should become increasingly important as ships operate more frequently under conditions of radar silence.

◆ SAMID/ASMD

Ships Anti-Missile Integrated Defense program and Anti-Ship Missile Defense program were conducted in the late 1960s and early 1970s, but their fruits remain in the current fleet, and their structure explains several current efforts. SAMID was established in July 1967 to meet the threat of Soviet-supplied antiship missiles (Styx, Shaddock, and the coast-defense Samlet) in Vietnam. This was well before the sinking of the Israeli destroyer *Eilat* by a Styx (October 1967), and SAMID was applied only to ships operating in Southeast Asia. The object was to improve a ship's reaction speed, but without purchasing much new hardware (so that a useful capability could be created in a short time). As in the past, this capability would be directed via CIC. However, in the interest of very quick reaction, SAMID also included a reflexive mode for bypassing CIC. Presumably, the reflexive mode was also a casualty mode, in the event CIC was hit.

Despite the reference to the long-range Shaddock, SAMID was conceived primarily to deal with short-range missiles approaching at relatively low altitude, hence visible only as they crossed the horizon. Hence the emphasis on quick reaction and on maximizing missile detection (e.g., by pressing fire-control radars into service as auxiliary horizon-search sets).

SAMID was conceived as a combination of immediate, near-term, and long-term phases; the near- and long-term elements later became the basis of the ASMD program. The immediate program, approved by the CNO late in 1968, emphasized doctrine and training, with a minimum of new hardware; it was intended for installation on an emergency basis on board *Adams* (DDG 15), *Belknap* (CG 28), and FRAM I (*Gearing*-class) ships deploying to Southeast Asia. It improves passive intercept detection, analysis, and display capabilities for immediate threats by modification or replacement of intercept receivers; it improved active detection by search radar through clutter suppression; and it reduced reaction time by providing horizon/sector scan in fire-control radars (see the entries for SPG-51 and -55), by using intersystem and intrasystem data links (integrated hardware and software), and by adopting specialized operational procedures.

The *Leahy* class's package consisted of (i) horizon search/sector scan for SPG-55B, which provided both additional search sensors and a means to reduce the system's overall reaction time; (ii) functional integration of the chaff-dispensing and other EW systems with missile and gun systems; (iii) shipboard operator and team training, using devices such as the radar video recorder (RAVIR). Equivalent modifications to the weapons systems of the DDGs and the gun destroyers were also provided. The cruisers and missile destroyers were provided with radar video processors (probably among the first ATDs in U.S. naval service) and with threat-warning receivers. Only the cruisers had NTDS, and their programs were modified. All of the ships were fitted with chaff launchers, which at that time meant chaff rockets. The gun destroyers were fitted with a new warning system, QRC 68/9 (the threat reactive system, SLG-19), and they received IR fuzes for their 5-in guns. RCA's SLQ-19 was shelter-housed, and it could automatically recognize and respond to the main-threat missiles (*Styx*, *Shaddock*, *Samlet*). When integrated with NTDS, it was redesignated SLQ-26.

Neither the DLGs nor the gun destroyers had automated CICs. That in itself limited their potential reaction time (apart from 7 ships, the DDGs still lack automated CICs). SAMID, therefore, provided simple intersystem data links for quicker reaction time, which allowed rapid graphic communication between EW and weapons systems and command and control. The basic system was designed for DDG 15, then modified for CG 28 and FRAM I. It consisted of 5 units: (i) a passive intercept unit in the EW area of CIC; (ii) an active ECM station in the EW area of CIC; (iii) an evaluator's station in the display-and-decision area of CIC; (iv) a weapons-control station (WCS) in the display-and-decision area of CIC; and (v) a unit at the passive ECM (chaff) remote-control station. The system was rigged so that passive intercept could pass an alert/threat bearing directly to FCS in the reflexive mode, as well as bearing/threat to the evaluator. It could also receive bearing/threat/search request from the evaluator, who could get threat data from FCS radars operating in search mode. Active ECM provided bearing/activity/radiation to and also received these data from the evaluator. The evaluator passed bearing/threat/assignment and FCS/chaff/fire-chaff-order/weapons-free to the WCS; and received threat/salvo-in-flight/chaff-fired. The WCS assigned FCS to a target in the reflex mode, assigned targets to chaff, and received chaff information (ready/fired/loaded).

Because SAMID had to be installed quickly, it could not entail major rewiring of CICs, or the installation of new computers. Most data were, therefore, transferred by synchro (i.e., analog bearing data) and by signals (relay closures) illuminating information indicators.

The cruisers, which had NTDS, were already (in effect) wired for the sort of information transfer and processing that SAMID provided. Their SAMID packages, therefore, did not include either a WCS or a separate evaluator.

The major entirely new hardware was the SLD-1 threat DF, which made reflexive action possible. The missile ships' active jammers (ULQ-6B) were modified.

SAMID was tested between October 1968 and February 1969

against simulated Soviet missiles, using small craft as simulated missile boats (*Komars*). In a cruiser, the search radar's reaction time (to weapon designation) was reduced, on average, from 107 to 33 sec; in a missile destroyer, from 97 to 43 sec. The fire-control radar's reaction time was reduced from, respectively, 51 to 17 and 23 to 14 sec. EW's reaction time was reduced from 107 to 23 sec and from 119 to 24 sec, respectively. The success of these tests led to a decision to install SAMID on board 20 ships: 4 cruisers (CG 30, 31, 33; CGN 35), 3 missile destroyers (DDG 9, 13, 14), and 13 FRAM I gun destroyers (DD 717, 718, 784, 806, 808, 832, 836, 851, 852, 869, 875, 886, 887). SAMID was designed for installation within 2 weeks, without a major shipyard availability, all to be completed between January and July 1969 at the rate of 1 missile ship and 2 gun destroyers per month.

By 1970 the near-term version was planned for larger ships as well as for destroyers: CVA 31, CVS 38, CGN 9, CLG 4, CG 11, CG 29, CG 30, CG 31, CLG 4, and DLG 11 (now DDG 42), for completion by mid-1971. SAMID Intermediate (for completion by the end of 1972) was planned for CVA 59 (now CV 59), CLG 7, CG 16, CG 17, CG 26, DDG 4, DDG 13, DDG 22, DDG 35, and AOE 1.

For the CG 28-class missile cruisers, the near-term version included a clutter suppressor and automatic threat detector for the SPS-10 surface-search radar, a minimum range kit for SPS-37/43, Mk 28 chaffroc launcher, improved EW (see below), a threat announcer system, radar-signal processing equipment (RSPE) for the GFCS (Mk 68/SPG-53) to reduce target acquisition time and improve ECCM, specialized training, and programming of a third NTDS computer (CP-642B) to include a SAMID module. The EW improvement was a new Threat Recognizer/Programmer, the American Electronic Laboratories SLQ-21, an automatic threat-recognition device for H-, I-, and J-bands. SLQ-21 programmed the appropriate countermeasures into the modified ULQ-6B. The system included an automatic threat library, probably embedded in the NTDS computer itself. The ships were fitted with a new multibeam-intercept antenna system (feeding WLR-1/3 receivers) and with combined passive-intercept receivers, as well as with an SLA-10 signal blanker (to protect the system against own-ship radiation). The SPG-55 radars were modified for continuous boat track and horizon/sector scan.

Again, the lack of a central combat-direction computer was a major drawback in non-NTDS ships. This time there was more scope for modification; non-NTDS ships were to be fitted with a data correlation-and-transfer system, DATACORTS, built around a CP-967 digital computer communicating with all the sensors and decision and action stations. DATACORTS was analogous to NTDS except that it did not include Link 11. It received inputs from all sensors, correlated and displayed their data, performed threat analysis, and recommended action. It also provided the necessary controls to initiate action; it recommended and assigned fire-control channels, active and passive ECM, and weapons, all based on the type and degree of the threat, the threat bearing, the availability of defensive weapons, and doctrine on rules of engagement.

The 2 test ships for this SAMID 70 were the *Jouett* (CG 29, for the NTDS version) and *Little Rock* (CLG 4, for the non-NTDS version).

Apart from this program, ASMD improvements were also made in large amphibious ships (LPD and LPH).

At about the same time a more integrated approach to greater radar effectiveness was under consideration: combination of all radar data in a single computer. This concept was practicable because so much work had already been done on automatic radar detection (ATD), partly in connection with SAMID. The different radars had very different characteristics, so their net probability of detection could be much greater than the capability of any 1 set. Once radar track data were in a computer, they could be compared to known flight profiles for quick threat identification and reaction. When it was begun in 1968, this approach was called the New Threat Upgrade, and ultimately

it led to SYS-1. The automated-threat-response ideas were also reflected in the design of the *Perry*-class CDS, which was intended largely to counter pop-up submarine-launched missiles (SS-N-7).

The next stage was a long-term ASMD program. As of 1970, it was expected that some form of ASMD would be installed on board about 250 ships by 1977. The first stage included the installation of what amounted to NTDS (a system called JPTDS, the Junior Participating Tactical Data System) on board 4 missile destroyers under the FY71 program.

Other ideas were also tested. On 30 August 1971 the *Lawrence* (DDG 4) was designated an ASMD test platform (FY72) under a quick-procurement program called Hip Pocket. She tested Sea Chaparral (which was later deployed in Southeast Asia on an emergency basis on board FRAM I destroyers), Redeye (the predecessor of the current Stinger), an IR search-and-track system (the predecessor of SAR-8), an interrupted-CW threat-warning radar (which might be considered the forerunner of TAS Mk 23, sharing the SPS-10 antenna), IR shielding to her funnels, a chaff mortar (the first test of RBOC), and a flame-thrower (an IR decoy) on her fantail. She used a computerized threat library to sound an automatic alarm in CIC. Hip Pocket was evaluated in February–June 1972. Hip Pocket II was authorized in September 1972 for the *Hoel* (DDG 13) and *Coontz* (DLG 9, now DDG 39). This program also included the prototype of the SQR-18 escort towed array. For the DDG, Hip Pocket II included Alert II ESM on the SPS-10 antenna mount, a passive engagement system (PES) in CIC, a shipboard IR surveillance system (SISS), a dual-spectrum imaging sensor (DSIS), an IR threat acquisition-and-verification system (ITAVS), an active-passive range-gated television (including a laser for ranging and dusk/night operation), and LLLTV. The SPS-10 was modified with an incoming-target alarm and a video clutter suppressor (it reacted to threats closing at Mach 0.5–3.0). The primary new weapon was a Hybrid Missile System carrying Chaparral, Hornet (laser-guided), and dual-mode Redeye missiles, with a TV/laser tracker on the mount. The ship also carried RBOC mortars and IR and radar decoys. The ship's SPG-53 GFCS radar was modified for better low-angle performance. The *Coontz* tested active defense by the army's Vulcan 20-mm cannon, controlled either by a lead-computing sight or by the Mk 68 FCS. The more elaborate Phalanx was already under development, under a QRC contract awarded to General Dynamics in 1969.

The strong emphasis on electro-optics reflects both the fear that radar could not deal effectively with low fliers and the experience built up during the Vietnam War. Presumably, experience in the 1973 tests showed that this technology was not yet sufficiently mature for production, but thatIRST was worth further effort (in the form of SAR-8).

ASMD fell victim to post-Vietnam finances. Many of the ideas tested in Hip Pocket were indeed pursued, but more slowly than might have been imagined under the intense pressure of the missile threat in Southeast Asia. The 4 FY71 DDGs were fitted with JPTDS, but not the remaining (planned) units. The new standard integrated jammer (to combine the threat-recognition and automatic-reaction features of SLQ-19 and -21 with the jammer to replace ULQ-6), Shortstop (SLQ-27), proved too expensive and had to be canceled in 1974 (the prototype was removed from the *Biddle* in 1979). The next-generation version of the wartime SLQ-19 was TRUMP (the Kuras-Alterman threat reactive upgrade modernization program), 2 of which were bought to upgrade existing ULQ-6B and -6C jammers and provide them with channelized receivers (SLR-12), at a unit cost of \$250,000 (FY75 dollars). SLQ-30 seems not to have been bought in any quantity by the U.S. Navy, but it was recommended to foreign navies using ULQ-6, and it may have been bought by Greece and perhaps Iran.

By about 1974, the ASMD EW program had led to DPEWS, the design-to-price EW system intended to replace Shortstop. SLQ-32 ultimately won this competition (in February 1977). At that time DPEWS was intended for smaller surface ships, for LAMPS III helicopters, and for some fixed-wing aircraft (prob-

ably P-3s and S-3s). Planned ship installations were: 60 ships with threat warning, wide-area, electronic surveillance and deceptive ECM (unit cost \$1.4 million in FY75 dollars); 115 ships with threat warning and wide-area surveillance (unit cost \$500,000); and 125 ships with threat warning only (unit cost \$300,000). At that time initial installations were planned for 1977. In addition, the program called for installation of SRBOC mortar-delivered chaff rounds, for 5-in chaff rounds, and for development of a long-range, dilution, decoy chaff rocket carrying RBOC (to succeed the Vietnam-era Chaffroc, which had been canceled because of technical problems).

By this time priorities had shifted. The preferred solution to the fast attack boat was offensive action, e.g., using the new Harpoon missile. The greatest perceived Soviet missile threat was the big air-launched antiship missile (AS-4 in particular). Longer-range active counters, such as improved Standard Missiles and NTU, seemed much more valuable. Chaff rockets could be abandoned because the missile-carrying bombers would have the fleet under observation for long enough to negate their confusion effect. Chaff mortars were more important as a contribution to last-ditch defense. Warning, in the form of SLQ-32, was terribly important, as was targeting assistance for Harpoon, in the form of improved DF systems such as Outboard and its ilk.

From the Falklands War (1982) on, however, the small fast attack boat and the short-range air-launched sea-skimmer became more and more important. Virtually the same solutions first proposed in SAMID and in ASMD are now being suggested (e.g., RAIDS). They are also now more practicable and less expensive. Given the number of ships in existence without any semblance of automated combat direction, systems like DATACORTS become much more interesting.

AIR-TRAFFIC-CONTROL RADARS

◆ SPN-35

Band: X (9000–9160 MHz)

Beam: (e) 3×1.15 (scans in 10- or 35-deg sectors) (a) 1.1×3.5 (tilted -1 to $+25$ deg)

Peak Power: 175 kW **Gain:** (e) 34 dB (a) 36.5 dB

Pulse Width: 0.2 or 0.8 microsec **PRF:** 1200 pps

Antenna Dimensions: (e) 30×152 in (a) 78×159 in

Antenna Weight: 3500 lb (total for radar, including radome)

SPN-35 (in the radome) on board the Spanish carrier *Principe de Asturias*, 1989. (S. Terzibaschitsch)

Although not strictly an air-defense radar, SPN-35 is included in this section because, as a blind-approach radar, it helps make all-weather carrier air operations possible. SPN-35 is typically enclosed in a radome and consists of separate antennas to measure the elevation (AS-1669) and azimuth (AS-1292) angles of an incoming airplane. In the table above, these antennas are distinguished as (e) and (a), respectively.

SPN-35 is a shipboard version of the land-based TPN-8 blind-approach control radar, mounted on a stable platform. First evaluated at sea in 1963, SPN-35 was designed to enable its operator to direct a pilot along a predetermined glide path to a point a mile from a ship, after which the pilot could land visually. SPN-35 was installed on board virtually all U.S. carriers, including amphibious ships, but it is being removed from full-deck carriers as part of the SLEP modernization program; the standard combination of carrier landing radars is SPN-41, SPN-42 (or -46), SPN-43A, and SPN-44. SPN-35 is manufactured by ITT-Gilfillan. It survives on board U.S. amphibious ships and on board the Spanish *Principe de Asturias*.

◆ SPN-43

Band: S (3590–3700 MHz) **Beam:** 1.5×45 deg
Peak Power: 850 kW **Gain:** 32 dB
Pulse Width: 0.6 or 0.25 microsec **PRF:** 1125 pps
Scan Rate: 15 rpm **Antenna Dimensions:** 120×150 in
Antenna Weight: 3400 lb (including pedestal)

SPN-43 is the solid antenna above the larger SPS-49 on board the carrier *Enterprise*, 1987. The tub below SPS-49 carries SPN-42, and the 1 below that carries a Mk 91 Sea Sparrow missile director. (J. Kuersner)

SPN-43, manufactured by ITT-Gilfillan, is the marshal or air-search component of the carrier-controlled landing system. SPN-43 can also function as a secondary or backup air-search radar. Maximum range in clear weather is 50 nm (35 nm in rain), and minimum range 250 yd. The antenna can be tilted from 2.5 to 6.0 deg.

◆ SPN-46/SPN-42

This planned low-probability-of-intercept (LPI) ATC radar is to replace SPN-42. Two SPN-46s were authorized in FY86, with

SPN-42 on board the carrier *John F. Kennedy*, 1986. (S. Terzibaschitsch)

engineering demonstration due in FY89. SPN-46 uses an existing radar antenna and standard navy computers. LPI will be achieved by frequency agility, which should also increase the effective echoing area of incoming aircraft and thus eliminate the need for radar augmentation in the form of the corner reflector currently used. LPI is essential because the ATC radar is the only system specific to the carriers; all other carrier radars are common to other ships. Thus the carriers can be identified passively only through their ATC emissions.

SPN-46 can control 2 landing aircraft at once. It has a 10-nm operating range and monitors a 4-nm approach-control zone. The radar operates both in Ka-band (33.0–33.4 GHz) and in X-band (9275–9345 MHz) at a peak power of 50 kW (pulse width 0.2 microsec, PRF 2000 pps). It scans at 12 scans/sec, searching over a 25×1 -deg box 1200 ft deep in range. Minimum range is 150 ft, and range resolution is 2 ft. Azimuth and elevation resolutions are 0.00274 deg, for accuracy in glide-slope calculation. Elevation coverage is $+30/-15$ deg, and azimuth coverage is ± 155 deg. The system uses two 4-ft dual-band antennas, with conical scan in Ka-band and monopulse operation (Cassegrain feed) in X-band. The associated computer is AYK-14, and the elements of the system are tied together by a 1553B bus. There are 3 operating modes: (I) closed-loop automatic landing, (II) ILS approach (position data are shown on the cockpit display), and (III) talk-down. The system is called PALS (precision approach and landing system).

SPN-46 is manufactured by Bell Textron. As of April 1990, it had been installed on board the carriers *Abraham Lincoln* and *John F. Kennedy*, and it was being installed on board the *Kitty Hawk* and *George Washington*.

SPN-42, of which SPN-46 is an LPI equivalent, is a dual-channel automatic-aircraft-landing system, each channel of which can handle 1 airplane at a time. Each channel employs a pair of antennas, a Ka-band dish (AS-1347/SPN-42) and a smaller X-band beacon receiver (AS-2407/SPN-42) rigidly mounted to the dish. The main dish tracks by conical scanning, using a 0.57-deg beam scanning at 6000 rpm. SPN-42 tracks the incoming airplane and transmits track data to NTDS; the system transmits course corrections back to the incoming airplane via Link 4A. There are 3 alternative operating modes: automatic, in which commands are sent directly to the autopilot of the airplane; semiautomatic, in which the pilot responds to corrections sent via a pointer in the cockpit; and a manual (talk-down) mode.

OPTRONIC SYSTEMS

◆ Mk 24 Target Designation Transmitter/WDS Mk 11

Mk 24 is the standard U.S. Navy optical target designator, transmitting target elevation and bearing to a ship's combat system. It consists of a pair of counterbalanced binoculars atop a pedestal. Elevation limits: $+90/-20$ deg. The transmitter proper weighs 210 lb and is 70 in high, with a swept radius of 12 in. A below-decks control unit (Mk 79) adds another 95 lb. When combined with a data transmitter, Mk 24 is part of WDS Mk 11, incorporating 4 (Mod 2 or 3) or 2 (Mod 4) Mk 24s.

◆ Mk 35 Optical Director/Model 985

This Kollmorgen periscope system was designed for the U.S. post-Vietnam small-combatant program of the early 1970s, for FCS EX-93. Mk 35 has been incorporated in the Korean *Paek Ku* class and in H930 Mods 0, 1, and 2. The periscope carries day/night stabilized optics plus a television. The operator can estimate range by stadimeter (i.e., by an angular measurement of a known distance on the target), or the director can track in bearing while radar is used for ranging.

Although this director is primarily optical, and primarily driven by the operator's joystick, Mk 35 has provision for automatic tracking using the television camera. Elevation FOV limits are $+80$ and -30 deg, the FOV itself being 8×32 deg. The director can slew at 80 deg/sec (e.g., when accepting designation from another source). Resolution is 0.2 m at 3000 m, or 0.9 m at 15,000 m in daylight; corresponding night figures (clear with quarter moon) are 1.5 and 7.5 m.

Model 985 is a slightly lighter and less expensive version of the Mk 35 developed by Kollmorgen; Model 985 is in the Taiwanese *Hai Ou* class, where it feeds a locally developed FCS based in part on H930. The operator's position is a desk with 2 handgrip controls, the eyepiece of the periscope being fixed above the control panel, 7 ft 2.25 in above the deck. There are 2 FoVs (wide for acquisition, narrow for engagement). The periscope can be fitted with a 1-in vidicon (silicon, target type) TV tube. Tracking accuracy is 1 mrad. Elevation limits are $+70/-25$ deg, and slew rate is 80 deg/sec (acceleration 120 deg/sec²). Low power: magnification $2\times$, FoV 30 deg, focus 10 m to infinity. High power: $8\times$, 7.5 deg, 50 m to infinity. The total system weight is about 235 kg.

Kollmorgen announced a more elaborate remote periscope system, Model 875, in 1980, but it seems not to have been sold.

◆ Director EX-46 Mod 0

Kollmorgen's electro-optical director for the *Arleigh Burke* class won a competition against Norden/SAGEM. It feeds data into the GFCs, whose only other sensor is the ship's SPY-1D radar. The director carries a television and a Kollmorgen Micro-FLIR; the latter scans a SPRITE array both horizontally and vertically (it is a hybrid-serial FLIR). There is no laser, neither for range finding nor for target designation. The above-deck unit is about 30 in wide and 28 in high and weighs about 300 lb. This contract was awarded in June 1990.

EX-46 replaces the abortive EX-121 Seafire electro-optical FCS, described in the previous edition of this book. Alternatives

closed out in favor of Kollmorgen and Norden were Contraves (Sea Hawk II, see Switzerland), Lockheed (offering the Swedish 9LV-series), Hughes (using a version of the Italian NA-18L carrying Hughes sensors), and McDonnell Douglas.

◆ CWDD (AN/KAS-1)

Texas Instruments's Chemical-Warning Directional Detector is a modified army TAS-6, mounted on a ship's railing or TDT pedestal. CWDD is a binocular direct-view FLIR that can also be used for intelligence collection and gunlaying. Production began in 1982.

◆ H930 Optronic Sensor (Modular Combat Optronics System)

This sensor is part of the H930 on board Taiwanese *Wu-jinn III* destroyers. It can receive designations from other shipboard sensors, or it can be used to designate targets to other sensors. The system operator chooses among correlation, centroid, and edge tracking modes. The horizon-stabilized platform on its pedestal carries a television camera, a laser, and a FLIR. A below-decks joystick positions the pedestal; switches on the joystick control functions such as zoom control, entering auto-track, laser firing, entering manual mode, FLIR control, and automatic video tracker control. Television and FLIR images are displayed on a common raster-scanned monitor on the below-decks console.

◆ Hughes E-0 Sensor (HIRE)

Hughes is developing a FLIR, HIRE (Hughes IR Equipment), for the export market, using the Selenia NA-30, NA-18L, or Medusa Mk 3 lightweight stabilized pedestal. The sensors have been selected specifically for the NA-18 pedestal. Hughes envisages a variety of optics in the 8–14-micron band for different applications. As part of this effort, NA-30 was tested on board the destroyer *Rodgers* (under the Foreign Weapons Evaluation program).

The optronics portion of the Hughes (H930) modular combat system and its display. The console carries a series of switches and a joystick, and the display is raster scanned. (Hughes)

The optronics portion of the Hughes (H930) modular combat system and its display. The console carries a series of switches and a joystick, and the display is raster scanned. (Hughes)

Hughes currently offers 2 alternative 3–5-micron sensors. One is a developmental HgTE focal-plane-array FLIR with a thermo-electric cooler, weighing about 6 lb, which should be useful in high-humidity conditions. Its alternative FOVs are about 2.5 and 6 deg, and it can detect a 0.1°C difference in temperature. This is a 2D second-generation array, scanning over a scene rather than staring. It was developed under the Thermal Weapons Sight program.

The alternative is a 512 × 512-element platinum-silicide staring array. It was developed as part of the low-cost focal-plane-array initiative.

HIRE is a more austere 8–12-micron common-module FLIR using a 60-element HgCdTe detector and a dual-mode tracker (correlation and centroid).

The Hughes laser is an eye-safe Raman-shift unit (1.54-micron wavelength), capable of both low and high (10 pps) pulse rates, the latter to track fast targets.

◆ LSEOS Mk II

Texas Instruments's Lightweight Shipboard Electro-Optical Sensor was announced in 1990. It is currently being tested at sea. LSEOS is based on a high-resolution thermal imager already in service with Chaparral missile batteries (and in production since 1983). LSEOS has already been tested on standard navy radar pedestals and integrated with an FCS; Texas Instruments states that it is currently being used in an unspecified naval application. LSEOS operates in the 8–12-micron range, has dual FOVs (15 × 20 and 2.0 × 2.65 deg), and weighs 80 lb (plus 20 lb for the control panel and 80 lb for the electronic interconnect unit). Resolution: 0.82 mrad using the wide FOV, 0.11 mrad using the narrow field.

◆ Model 975

Kollmorgen's TIS (thermal imager system) director, the sensor of which is mounted in a 2-axis stabilized turret, feeds a desk-type console below decks. The FLIR has wide and narrow FOVs, for target acquisition and for target identification and tracking. Wide FOV: magnification 3.75×, 8.5 × 1.6 deg, focus from 50 m to infinity. Narrow FOV: 14×, 2.1 × 6.4 deg, focus from 50 m. Elevation limits: +80/–20 deg. Slew rate is 0–80 deg/sec (acceleration 360 deg/sec²). Tracking accuracy is within ±1 mrad (stabilization is within 0.1 mrad).

The FLIR is a hybrid parallel-serial type developed by Kollmorgen (Model 208S MICROFLIR) using an 8-element SPRITE detector. A 30 × 10-m target can be detected at 20 km and recognized at 11 km in a light haze (10 km optical visibility, 70% humidity).

The director box is 20.75 in long and has a square cross section. Above the FLIR, it has space for a CCD television or an Nd-YAG laser range-finder. Other options are a slave mode (or radar tracking), a lead-angle computer for small-caliber weapons, and an interface to an FCS.

The single-sensor box can be replaced by a wider one, carrying a FLIR and a television camera side by side, with the laser range-finder above; in this form Model 975 is a full optronic director.

◆ Mast-Mounted Sight (MMS)

McDonnell Douglas's Mast-Mounted Sight was originally developed for army OH-58D helicopters. During 1989, however, it was fitted to *Perry*-class frigates operating in the Persian Gulf, primarily to detect floating mines. Human lookouts had proved ineffective because of the heat, dust, and humidity. Reportedly, it was also quite useful against fast attack craft and low-flying aircraft, in effect as an interim substitute for SAR-8. The USS *Crommelin* and at least 1 other ship were fitted, and as of September 1989, 7 more units were on order. The spherical turret of the sight is mounted on a bridge pedestal on the centerline, controlled by an operator in CIC. There are also 2 other displays, 1 of them on the bridge. As installed on board the *Crommelin*, the sight is used only for target acquisition, but it can be modified to control weapons as well. The U.S. Navy first experimented with the MMS in 1987, testing it on board a *Knox*-class frigate.

The spherical turret carries a FLIR, a daylight television camera, and a ranging/designating laser; tracking is digital. Its unique value in a helicopter is that it is mounted above the rotor, so that the helicopter can function from ambush, its body and even its rotor hidden by trees. Principal navy changes were: deletion of the laser range-finder/designator and optical bore-sight assembly, and control and display installation for ship adaptation. A redesigned laser range-finder is now an option.

Turret slew rate is 60 deg/sec; bearing limits are ±190 deg and elevation limits are ±30 deg. The FLIR (8–12 microns, 6.6-in aperture, 120-element common module HgCdTe detector) has 2 alternative magnifications, 3× and 10.35× (corresponding FOVs are 9.6 and 2.8 deg). Resolution is 240 lines, processed by a digital scan converter to 875 lines. There is also a television sensor (TVS) using a low-light silicon vidicon (1-in-diameter tube) operating in the 0.65–0.9-micron range, with

The Mast-Mounted Sight on board a *Perry*-class frigate. (McDonnell Douglas)

700-line resolution in an 875-line video format; aperture is 4 in, shared (in the army version) with the laser range-finder/designator. Alternative TVS FOVs are 2 and 8 deg. Total turret weight is 73 kg (161 lb).

In army tests, the criterion to detect a target was to get 2 lines on it; recognition took 12 lines.

MMS growth options proposed by McDonnell Douglas are: installation of a laser range-finder, a manually trained day/night gunsight for 0.50 cal/25-mm guns, integration with the Mk 92 fire control for 76-mm-gun fire control, an improved mounting position (presumably on a mast), a better control/display (for faster operator response, target acquisition, and failure detection/correction), improved protection using ship services such as chilled water, increased gimbal travel (for better air search/track and better operation in high sea-states), and better magnification for greater effective range and better defense against sea-skimmers.

McDonnell Douglas Electronics is marketing an improved version as Euro-Sight, adding a TOW tracker, an improved thermal imager, and a multitarget tracker. Euro-Sight incorporates a GEC TICM II thermal imager. The GEC camera reportedly provides 50% more range than the U.S. Common Module unit in the current sight, with only half the electronics. The Euro-Sight can track up to 4 targets simultaneously. McDonnell Douglas hopes to halve the cost of the sight (to under \$1 million), partly by using VHSIC chip technology to cut the number of circuit cards from 32 to 12 or 13, at the same time increasing processing power from 1 to 7.5 MOPS. Both the air force and the U.S. Navy have reportedly shown interest.

As of mid-1989, 142 MMS (out of an army requirement for 592) had been delivered.

◆ Rockwell Tactical Imaging Sensor

Rockwell (Autonetics) showed a FLIR at the U.S. Navy League show in 1990; it will go to sea on board a *Spruance*-class destroyer as an adjunct to existing point-defense sensors. It uses

a 256×256 -element, 3–5-micron staring array; the wavelength was chosen for maximum target contrast. The system is fully automatic and has a digital output. No weights or dimensions were given.

◆ Sea Tiger

Texas Instruments's optronic FCS was tested by the South Korean navy in 1985. The stabilized cylindrical body, on trunnions, carries a laser range-finder/designator next to a day television camera, above a larger-diameter thermal imager (as used in Night Chaparral). There is an automatic video tracker, which can use either the television or the infrared image. The 1-operator console is below decks. Sea Tiger was originally designed to control guns and surface-to-surface missiles, but it can also control SAMs, since it can elevate to 70 deg. Frigates can be acquired and tracked at up to 14 km. The pedestal-mounted director weighs 270 kg and has a working circle (radius) of 60 cm.

Sea Tiger itself was not commercially successful, but a few derivatives (Sea Dragon) were sold in the Far East, presumably in Korea. Sea Tiger was intended for use with the Sea Ray laser-guided surface-to-surface missile.

◆ TIMS

Texas Instruments's thermal imaging multisensor (FLIR, CCD daylight camera, and CO₂ laser) is for land and sea applications in trackers and FCSs. TIMS has a stabilized 2-window turret with a stabilized mirror inside. The FLIR has wide ($\frac{1}{2}$ mrad, 2.3×3.1 deg, f/2.0) and narrow ($\frac{1}{8}$ mrad, 6.9×9.2 deg, f/1.9) FOVs. Field of regard is $+75/-20$ deg in elevation (360 deg in azimuth). The television is a high-resolution CCD type (245×780 pixels), with an FOV similar to that of the FLIR. The laser is integrated with the FLIR. Range is about 10 km. Tracking is digital.

See also electro-optical enhancements to the Mk 68 GFCS, below.

GUN AND MISSILE FIRE-CONTROL SYSTEMS

The new *Arleigh Burke* (DDG 51) is the first U.S. surface combatant without any independent gunfire-control system as such. The SPY-1D radar is sufficiently precise to track targets and shells, for improved accuracy and reaction time. A gun-mount processor and display provides an alternative method of gun computing and a backup mode. The gun weapons system as a whole is designated Mk 34, consisting of the Mk 45 gun (5-in/54) plus a Mk 160 computer (which does the ballistic computation).

◆ Mk 33

This antiaircraft director survives only on board the Chilean cruiser *O'Higgins*; it was the predecessor to the Mk 37 of World War II. Unlike Mk 37, Mk 33 incorporates its computer (Range Keeper Mk 10) in its above-decks rotating structure. This system cannot cope with modern aircraft, and is presumably relegated to controlling 5 in/25 guns against surface targets. Maximum target speed is probably 380 kt (there is a special "dive attack" feature to deal with targets diving at up to 400 kt). Including a $\frac{1}{4}$ in shield, Mk 33 weighs about 15,500 lb.

◆ Mk 37 (GFCS)

The standard U.S. dual-purpose FCS of World War II was designed primarily to control 5-in gunfire. In the U.S. Navy, Mk 37 survives only on board the 4 battleships and the 2 reserve cruisers (*Des Moines* class). It also survives on board many ex-U.S. destroyers in foreign navies. All existing versions employ the Mk 25 fire-control radar. These directors carry 15-ft stereo range-finders. Mk 37 was the first U.S. antiaircraft FCS to employ a below-decks computer (Mk 1A), separate from the above-decks optics and, later, the radar. Mk 37 is a linear-rate system, most effective at relatively long range. Post-1945 improvements included automatic radar tracking, high peak power (250 kW in the Mk 25 radar), and 800-kt maximum target speed.

Mk 37 was superseded by Mk 67 and then by the very similar Mk 68. For a typical version, Mod 62, operating limits were a lead angle of 30 deg and a range rate of ± 450 yd/sec. Detection and tracking ranges were 100,000 yd, and maximum computed range was about 20,000 yd. Total weight was 40,150 lb including the below-decks computer, and the working circle radius was 100 in. Elevation limits: $+110/-25$ deg.

◆ Mk 38 (GFCS)/Mk 34/Mk 54

The *Iowa* class's 16-in GFCS was the first U.S. application of amplidyne drive. Mk 38 incorporates a stable vertical (Director Mk 41) and a long-base (26 ft 6 in) stereo range-finder, as well as a ranging/spotting radar (Mk 13). The main functions of the aloft director are to obtain target range and bearing, and level angle and cross-level (which are also supplied by the below-decks stable vertical). Weight is 50,450 lb above decks and 10,305 lb below decks, with 12 crew above and 20 crew below decks (2 plotting rooms). The associated computer is Range Keeper Mk 8. The director operates in primary control (observed target bearing transmitted directly to Range Keeper in plot). The director can be manually driven (by hand wheels) or power driven.

Because the computer is electromechanical, it requires a special cam for each combination of projectile and velocity. Cams exist for the 2700-lb AP shell (2500, 2300, and 1800 ft/sec) and for the 1900-lb HC shell (2690, 2525, and 2075 ft/sec). The latter shell did not enter service until late 1942, and ships did not receive the necessary cams until late in the war or postwar. Calculating limits are 45 kt (target speed) and 50,000 yd.

Ships were completed with a Mk 40 standby director in their conning towers, connected to a small radar. In addition, the turrets (Nos. 2 and 3) have their own long-base (46-ft) stereo range-finders and Mk 3 analog fire-control computers.

A Mk 48 shore-bombardment computer was added to the forward plotting room in the 1950s; a second unit was added aft upon modernization (in the *New Jersey*, for service in Vietnam). In addition, upon modernization 2 HP-85 digital computers were added, 1 to estimate initial velocity for each shell on the basis of erosion, powder temperature, and previous shell velocities from that gun; the second to correct for trunnion height, target height, earth curvature/rotation, and temperature. In addition, the system can correct for errors in the cams of the Mk 8 Range Keeper.

The system as a whole is less than satisfactory because it still relies on a few pre-cut cams to deal with a wide variety of current

and new shells and ballistic conditions. The ships will, therefore, be modernized with new Mk 160 computers (as in the new *Arleigh Burke* class) tied to the existing 16-in FCSs.

As an interim measure, commercial microcomputers have been used, at least since the mid-1980s, running software developed for more modern fire-control computers.

Mk 34, essentially a smaller-caliber equivalent to Mk 38, survives only on board the Chilean cruiser *O'Higgins*. This director carries a Mk 13 (or the equivalent Mk 8 Mod 3) radar. Mk 34 carries an 18-ft range-finder and weighs 41,300 lb (topside) plus 10,742 lb (below decks). Topside crew is 16, with 5 more below decks. The associated computer is Range Keeper Mk 8 (which is also used in the similar Mk 38 battleship director). Maximum target speed is 45 kt.

Mk 54 is the GFCS on board the 2 surviving *Des Moines*-class cruisers. It was designed to replace the earlier, cramped Mk 34 and to provide some antiaircraft capability (against targets with speeds up to 800 kt). Like Mk 34, Mk 54 incorporates a Mk 8 Range Keeper (to track surface targets), but it also includes 2 antiaircraft computers, Mk 1A (as in the dual-purpose Mk 37 system) and Mk 48 Mod 1. As in the earlier system, the associated radar is Mk 8. Total topside weight is 40,452 lb, and below-decks weight is 13,792 lb; it requires 10 topside personnel and another 20 (for 2 plotting rooms) below decks. Mk 54 carries a 26.5-ft range-finder.

◆ Mk 51/52/63/70 (GFCS)

Mk 51, essentially a remote lead-computing gunsight, was the most successful World War II light director. Mk 52 was a modified Mk 51 carrying a Mk 26 range-only radar, primarily for destroyer escorts. The typical weight of Mk 51 was 710 lb above decks. Mk 52 weighed 1710 lb above decks and 1320 lb below decks. Mk 52 incorporated Computer Mk 6 for surface fire. Operating limits for Mk 52: lead angle 20 deg, target speed 350 kt, range for surface fire 12,000 yd, range for AA fire 7000 yd.

Mks 51 and 52 survive in some foreign navies.

Mk 63 is essentially a Mk 51 with a tracking radar (Mk 34 or SPG-50) on the gun mount itself. Typical weights: Mod 23, 3900 lb; Mod 24, 4000 lb; Mod 28, 5300 lb; Mod 29, 5400 lb. Operating limits: detection range about 37,000 yd; tracking range about 35,000 yd; computing range about 7000 yd. Maximum lead angle 20 deg, maximum range rate $+350$ kt, -800 kt. Range limits are 800 and 7000 yd. The above-decks director pedestal (carrying a Mk 29 sight) weighs 1300 lb.

Mk 70 was a modified Mk 63 in which radar range was introduced automatically, rather than manually, into the lead-computing gunsight. Mk 70 was installed on board the helicopter carrier *Iwo Jima*, to control twin 3-in/50 guns Mk 33.

Mk 38 director (with Mk 13 radar) on board the USS *Wisconsin*, 1988. In the foreground is a Mk 37 director carrying a Mk 25 radar, turned toward the main battery director. (S. Terzibaschitsch)

Mk 52 gunfire-control system with Mk 26 range-only radar, on board a destroyer escort. (Naval Historical Center)

The other ships of the class had Mk 63 directors. Mk 70 had an SPG-52 radar, and maximum target speed was 650 kt.

Mk 70 Mod 2 equips the former U.S. *Claud Jones*-class escorts in Indonesian service.

◆ Mk 56 (GFCS)

This standard U.S. postwar 3-in/50 blind-fire director also incorporated 5-in/38 or 5-in/54 ballistics. Unlike Mk 37, Mk 56 is a relative rate, i.e., a medium-range, system. In such a system the overall fire-control problem is approximated by concentrating on the motion of the target relative to the firing ship at any given moment; the faster the targets, the less the effect of omitting the motion (other than roll and pitch) of the firing ship. The firing solution is generated within 2 sec of beginning tracking a target. Mk 56 carries a Mk 35 (SPG-35) radar and employs a Mk 30 below-decks computer. Mk 56 was the first U.S. blind-fire director without an optical range-finder. Operating limits: lead angle 30 deg, range rate ± 260 yd/sec. Maximum detection-and-tracking ranges are 30,000 yd, and maximum computing range is 15,000 yd. Elevation limits: $+82/-23$ deg. Total weight: 17,000–26,000 lb, with a 51-in (radius) working circle. Above-decks weight is 9809 lb.

Mk 56 gunfire-control system, in this case controlling 5-in/38 guns on board a U.S. *Essex*-class carrier, now discarded. (U.S. Naval Institute)

◆ Mk 68 (GFCS)

Mk 68 is a 5-in linear-rate GFCS, found on board many U.S. cruisers, missile destroyers, and frigates. It employs the SPG-53 radar and was succeeded by Mk 86. Mk 68 carries an 11-ft stereo range-finder and uses 2 below-decks computers, Mk 47 and Mk 116. Mk 47 was an electronic/electromechanical analog replacement for the electromechanical Mk 1 of the Mk 37 FCS; and Mk 47 provided faster, smoother solutions. It was first employed in the postwar Mk 67 director. Mk 68 was essentially a Mk 67 modified to handle supersonic targets. Limits: detection range about 90,000 yd, tracking range about 100,000 yd, computing range about 18,000 yd. Maximum lead angle 50 deg, maximum range rates ± 1125 yd/sec. Elevation limits $+85/-20$ deg. Above-decks weight is 15,300 lb (working-circle radius 80 in). Total installed weight: 26,600–28,000 lb.

Texas Instruments produced 2 electro-optical adjuncts to Mk 68. In 1972, under the Quick Reaction (QRC) program, over a dozen Mk 68s were modified to include a FLIR, laser range-finder, displays, and the necessary control electronics. The system could then operate at night or in low visibility without emitting radar signals. Ships so modified were used extensively during the closing stage of the Vietnam War; because existing equipment was used, the first installation was completed 8 weeks after contract award.

In 1973, based on the QRC work, Texas Instruments was awarded a contract for a Mk 68 Electro-Optical Sensor System

Mk 68 director, with its SPG-53 radar (USS *Pharris*). (U.S. Navy)

(EOSS), as part of the Navy Gun Improvement Program. The Mk 68 optical range-finder was replaced by a high-performance FLIR plus a laser designator/range-finder, and an automatic video tracker was installed. The tracker pointed the laser, which could track to better than 0.2 mrad independent of the director. The EOSS could receive designation from other ship sensors or could acquire targets independently during conditions of radar silence. The system was installed on board the missile destroyer *C. F. Adams* and was used for 3 yr. EOSS could be recognized by the installation of the laser and television camera alongside the director turret, on its left-hand side.

Versions:

Mod 0 Original version for *Forrest Sherman* class, using the Mk 47 Mod 3 computer. Total weight was 28,000 lb. Mod 1, for the same class, used a modified computer (Mk 47 Mod 4). Mod 3, for later *Forrest Shermans* and for the *Mahan* class, had a modified computer (Mk 47 Mod 5) and added computer Mk 116. All of these versions had dual ballistics (5-in/54 and 3-in/50). In Mod 3, for the first time the radar transmitter-receiver was located in the director shield instead of below decks. Mods 1 and 3 weighed 28,800 lb.

Mod 4 *Adams*-class version equivalent to Mod 3.

Mod 5 Replacement for Mod 1 with radar moved to director shield, for DD 940–944.

Mod 6 *Mahan*-class version with computers Mk 47 Mod 7 and Mk 116 Mod 0 and SPG-53A rather than -53 radar (1961). There was a similar Mod 7 for this class.

Mod 8 *Belknap*- and *Truxtun*-class version using SPG-53A radar and computers Mk 47 Mod 9 and Mk 116 Mod 4. It controlled the 5-in/54 gun against both surface and air targets, and 3-in/50 guns against surface targets only (1962).

Mod 9 For *Mitscher*-class destroyers converted to missile ships with SPG-53B radars (which had provision for CW injection, for missile control). The computers were Mk 47 Mod 8 and Mk 116 Mod 3 (1965). These ships no longer exist.

Mod 10 For *Forrest Sherman*-class destroyers converted to missile ships with SPG-53B radars; the computers were Mk 47 Mod 5 and Mk 116 Mod 0 (1965). These ships no longer exist.

Mod 11 For *Knox*-class frigates (FF 1052-1077) with SPG-53A radars and computer Mk 47 Mod 10 (no Mk 116), to control 5-in/54 guns. This version was also used on board Spanish *Baleares*-class frigates.

Mod 13 For *Joseph Hewes* (FF 1078), with provision for RAP (rocket-assisted shell) fire, using the Mk 47 Mod 11 computer. The radar was SPG-53A, and there was no Mk 116 computer (1969).

Mod 14 For *Knox* class (FF 1056, 1068, 1072, 1075, 1078, 1079), to provide them with a surface-missile capability (Standard ARM, the Interim SSM), using ORDALT 6010A. These ships are also fitted with ORDALT 6948, to allow them to fire RAP rounds. The computers are Mk 152 Mod 1 and Mk 47 Mod 10, and the ship is also fitted with a Mk 154 Mod 9 range computer (digital ranger ORDALT 6894). The radar is SPG-53D (1972).

Mod 15 Was a special electro-optical system fitted on board the USS *Adams* in July 1975 and removed in June 1979. It employed an EX 160 Mod 0 computer and electro-optical sensor set EX 1 Mod 0 (which included a laser ranger) with radar SPG-53F. This experimental system temporarily replaced the ship's Mk 68 Mod 4.

Mod 16 For the USS *Adams* and *Belknap*, using computer Mk 160 Mod 1 (1 gun) or Mod 2 (2 guns) and radar SPG-53F (1979).

Mod 17 *Belknap*-class system replacing Mod 8 (replaces Mod 16 on board *Belknap*) using computer Mk 160 Mod 3 and radar SPG-53F (1979).

Mod 18 *Mahan*-class system to replace Mod 6, using computer Mk 160 Mod 3 and radar SPG-53F (1979).

Mod 19 *Adams*-class system (for DDG 2-16, 18, 21, i.e., those that were not fitted with Mk 86) to replace Mod 4, using computer Mk 160 Mod 3 and radar SPG-53F (1979).

Mod 20 *Knox*-class system to replace Mods 11 and 13, using computer Mk 160 Mod 3 and radar SPG-53F (1979).

♦ Mk 69

GUNAR fire-control system is extinct in the U.S. Navy but still in use in the Royal Canadian Navy. Mk 69 could handle supersonic targets. Tracking range was 40,000 yd (computing range 10,400 yd); maximum target speed was 1250 kt, and maximum lead angle was 30 deg. The director was intended for use against air targets only, controlling guns firing proximity-fuzed ammunition. Typical topside weight was 5000 lb, with another 8400 lb below decks, and working-circle radius was 36 in. Personnel: 2 in the director and 2 below decks. Mk 60 is the Canadian designation for the solid-state version now being substituted for the original U.S. Mk 69 (with the SPG-515 radar).

♦ Mk 74 (MFCS)

Mk 74 is the SM-1(MR) GMFCS in U.S. and foreign service. It consists of the SPG-51 radar on a Mk 73 director plus a computer, originally Mk 118 (1 per radar). The computer aids the tracking radar in acquiring a target and projects the target's position ahead for rate-aided tracking. It generates orders for the Tartar launcher (and, at least in the case of an *Adams*-class destroyer, can simultaneously generate orders for two 5-in/54 mounts). It also generates Tartar missile orders and the display data for target evaluation in the WDE. The associated WDS is Mk 4 (Mk 11 when it is integrated with NTDS).

The elevation limits of the 2-axis-stabilized Mk 73 director are +83/-30 deg. It carries both the SPG-51 radar antenna and an LLLTV camera (Mk 15).

The prototype was completed in 1958, and the current Mod 2 appeared in 1969. It incorporated solid-state electronics and direct-drive motors rather than the earlier amplidynes (and vac-

uum tubes) of Mods 0 and 1. Mod 3 was never produced, and Mod 4 was developed into a Mk 80 director for Aegis (the abortive version with a tracking rather than a slaved illuminator). Mods 5 and 6 are modernized versions of Mods 0 and 1 (Mod 6 is a modernized version for *Adams*-class missile destroyers, first delivered in September 1979). The current Aegis slaved director (Mk 82) is a lightweight (2680 vs. 7600 lb) version of Mk 73, capable of higher angle rates.

FCS Mk 74 is primarily for missile control, but it can also provide tactical data to the associated WDS (Mk 4 or Mk 13). Normally, the WDS controls the GFCS and the 2 Mk 74 MFCSs separately, but the 2 systems interconnect through the WDS. The Mk 68 on board most SM-1 ships can track targets sufficiently accurately to slave the 2 SPG-51s if their tracking elements fail. The Spanish *Baleares* class, with only a single SPG-51, has a second Mk 118-2 computer associated with the Mk 68 GFCS to provide a second missile-control channel. This computer accepts target position and rate functions from the Mk 47-12 computer of the GFCS.

The most important development in this series was Tartar D (digital Tartar, using SPG-51D: Mk 74 Mods 4 and 5). Tartar D was conceived in response to a revised SOR. Its extended tracking range more nearly matched the extended range capability of the SM-1(MR), compared to the earlier Tartar.

Capabilities of the original Mk 74 system (Tartar missile, predecessor of SM-1(MR)): acquisition range, 120 kyd (on an F6F airplane); reliable tracking range, 20 kyd; minimum range, 500 yd; range rates, 50-1320 kt; angle rate, up to 120 deg/sec.

About 1975 the Tartar FCS was credited with a tracking capability between 2000 and 200,000 yd; targets were acquired at 120,000 yd (the associated 3D radar could detect targets at 160-240 nm, and the associated 2D radar could detect them at 20-285 nm, depending on the radar).

Versions:

Mod 0 Original version for missile destroyers, using an analog computer (Mk 118). The radar was SPG-51.

Mod 1 Version for the 3 *Albany*-class missile cruisers, using the Mk 118 analog computer and SPG-51 radar. Total weight was 19,000 lb.

Mod 2 *Brooke* (FFG 1), DDG 31, and DDG 35-class version, with WDS Mk 4. The computer was Mk 118 Mod 2, and the radar was SPG-51B.

Mod 3 Revised version for missile destroyers and frigates, with SPG-51C radar.

Mod 4 Tartar-D (digital) version, for the *California* class (1969), with NTDS (WDS Mk 11, SPG-51D). It was similar to Mod 3, but with a digital (Mk 152) rather than an analog computer, with SPG-51D rather than -51C, and with a Mk 73 Mod 2 director. Estimated total weight was 65,000 lb. The *Californias* were the first ships to have SPG-51D.

Mod 5 *Virginia*- and *Kidd*-class version (1969) of Tartar-D, with Mk 26 dual-purpose launcher (WDS Mk 13).

Mod 6 Mod 0 with a digital computer (Mk 152 Mod 1), the digital update for DDG 2-24 (1969); total weight was about 19,000 lb. The radar was SPG-51C.

Mod 7 Tartar system for DDG 31-34 conversion, similar to Mod 6 (Mk 152 computer, SPG-51C radar).

Mod 8 Similar to Mod 6 but WDS Mk 4 is upgraded to Mk 13 Mod 1/JPTDS (Junior Participating Tactical Data System). The WDS Mk 13 computer is integrated with the Mk 152 Mod 1 computer (1971). This is the FY71 ASMD program upgrade, for 4 DDGs (DDG 9, 12, 15, and 21). The radar is SPG-51C.

Mod 9 The Mk 152 computer is replaced by UYK-7 (1974); this version is smaller and lighter than earlier ones (for the *Arkansas* and projected further ships of that class).

Mod 10 *Perry*-class version with UYK-7 computer (1974).

Mod 11 Mk 152 (digital computer) version for *Adams*-class destroyers (DDG 2-15), 1974. The radar was SPG-51D (Tartar-D).

Mod 12 Mk 152 (digital computer) version for the *Brooke* (FFG 1) class, 1974. The radar was SPG-51D (Tartar-D).

Mod 13 Derived from *Mod 8*, and similar to it, for modernized *Adams*-class destroyers (SM-1 missiles). It was designed to work with WDS Mk 13, and it used the SPG-51C director, and LLLTV Mk 5.

Mod 14 CGN/SM-2 version (1983). The radar is SPG-51D. This version includes an OJ-194 console for FCS supervision. Total weight: 42,665 lb.

Mod 15 *California*-class NTU Baseline, with CWAT (CW acquisition and tracking). Total weight: 44,835 lb.

◆ Mk 76 (MFCS)

Mk 76 is the SM-1(ER) GMFCS in U.S. and Italian (*Vittorio Veneto*— and *Andrea Doria*-class cruisers) service; it was formerly on board the Dutch cruiser *de Zeven Provinciën*. Mk 76 is broadly analogous to Mk 74, consisting of a radar (SPG-55) atop a Mk 74 director with a computer (originally Mk 119). Originally controlling Terrier missiles, Mk 76 could track targets at speeds as great as Mach 2 and with angle rates as great as 120 deg/sec (60 deg/sec in elevation). The maximum acceptable range rate was 40,000 yd/sec. The original SPG-55 radar could track targets out to 60 nm. By 1975 the maximum tracking range had been increased to 120 nm and the maximum target speed to more than Mach 2.5. At that time the system could control SM-1 missiles against targets out to 80 kyd and at altitudes of 50,000–80,000 ft. Total system reaction time was given as 60 sec, including target-data processing, threat evaluation, launcher loading, and weapons assignment. The launcher (Mk 10) took 45 sec to fire its first salvo and 30 sec between later salvos.

Unlike the earlier Mk 71, 72, and 73 Terrier FCSs, Mk 76 could be retrofitted for CWI (originally 2 kW, later 5 kW). By 1965 all *Mod 0*s had been retrofitted to the dual-mode *Mod 1* version (SPG-55A); from 1964 on all could fire the nuclear beam-riding version of the missile. Mk 76 may also have been designed from the first for ultimate integration with NTDS.

Mk 76 differed from Mk 74 in that it had no gunfire-control capability. Its Mk 119 computer was very similar to Mk 118 but was designed to control longer-range Terrier missiles. The system was designed to control its beam-riding Terrier missile in shore bombardment and in surface-to-surface fire. Unlike Tartar, Terrier seemed suitable for such operation because it was command-guided (in its beam-riding form). There were 2 surface-to-surface beam-rider modes, 1- and 2-director. In 1-director mode, the radar tracked the target in azimuth only, and the missile was programmed in elevation to the target (the radar had to elevate to guide the missile, and the target therefore had to be in the lower portion of its beam). In the 2-director mode, 1 director tracked the target, and the associated Mk 119 computer provided the other director with missile orders. In shore bombardment, 1 director could track a beacon ashore while the other controlled the missile. In the absence of command guidance, a semiactive missile could still be fired at a ship, but only at short range; hence the interest, in the mid-1970s, in active and ARM versions of SM-1. Command guidance (in SM-2) restores the capability for longer-range surface-to-surface fire.

The associated WDSs are Mk 3 for the *Farragut* class, Mk 6 for the cruiser *Long Beach*, Mk 5 for the carriers (all now removed), Mk 7 (missile cruisers CGs 16–35), and Mk 11 (ships refitted with NTDS integrated with their FCSs).

Versions:

Mod 0 Version for *Farragut*-class destroyers (DDG 37 class) with SPG-55 radars and the Mk 119 *Mod 0* computer, first on board *Coontz* (DDG 40) in 1959. In 1964 Mk 119 *Mod 0* was modernized into a configuration equivalent to *Mod 3* or *Mod 4* to ac-

commodate the new PEP (performance extension program) Terrier missile, which had the new Mk 30 sustainer motor. The computer was provided with new missile-control functions to aid the missile's speedgate in quickly locating target Doppler and to provide optimized homing trajectories in longer-range flights. The first 4 ships of this class were completed with the earlier Mk 73 FCS (with SPQ-5A radars) but were modernized with Mk 76.

Mod 1 Dual-mode version (SPG-55A radar) with Mk 119 *Mod 0* computer. All *Mod 0*s were upgraded to *Mod 1* configuration. Total weight: 29,400 lb (11,000 lb topside, 18,400 lb below decks). That included 25,400 lb of radar and director and 4000 lb of computer. This was the version initially installed on board the cruiser *Long Beach* and the carriers *Kitty Hawk* and *Constellation* (now removed).

Mod 2 Upgraded version with SPG-55B radar and Mk 119 *Mod 0* computer. *Mod 2* was first installed on board the *Worden* (CG 18) in 1963. This radar enjoyed better CCM through purely random PRF jitter, extra-high tracking power (5 kW average), and pulse compression.

Mod 3 Version with SPG-55B radar and Mk 119 *Mod 3* computer, for the *Belknap* class and the carrier *America* (CV 66, now removed). *Farragut*-class destroyers were upgraded to this version.

Mod 4 Version with SPG-55B radar and Mk 119 *Mod 4* computer for the *Wainwright* (CG 28) class (integrated with NTDS). Total system weight was about 30,000 lb.

Mod 5 Version with SPG-55B radar and Mk 119 *Mod 5* computer for the *Leahy* class as modernized from 1968 on, with NTDS and WDS Mk 11.

Mod 6 Version with SPG-55B radar modified with CW Acquisition and Track (CWAT) and Mk 152 computer (in place of the analog Mk 119 of *Mods 3, 4, and 5*). CWAT provides an additional tracking channel for the SPG-55 radar. *Mod 6* was first installed in the *Belknap* class. This designation was first applied in March 1972.

Mod 7 Version with SPG-55B plus a tracking module (for better C-band performance, especially in sea return) and a Mk 152 computer (in place of the analog Mk 119) for the *Dahlgren* (DDG 43) as modernized. *Mod 7* is the baseline for the CG/SM-2(ER) system (*Mod 9*). This version was installed on board the *Belknap* (CG 26) as repaired in 1976.

Mod 8 Version with SPG-55B, CWAT, and a tracking module, the Mk 152 computer for the *Bainbridge* (CGN 25) as modernized. This version incorporates a UD-1230 console for ECCM, has a single scan mode for target acquisition, and self-monitors missile casualties.

Mod 9 SM-2(ER) version with new Mk 152 computer (adds 500 lb), February 1974. The associated SPG-55B radar has a new X-band mode and serializer, a rear reference antenna, and X-band frequency agility for SM-2(ER). This version deletes the beam-riding Terrier capability from *Mod 8*. *Mod 9* was intended for all the Terrier (now SM-1(ER)) ships. This version could control the SM-2(ER) missile but was not the full New Threat Upgrade.

Mod 10 New Threat Upgrade version, to control the SM-2(ER) missile, using the Mk 152 computer. System weight is 31,000 lb. Capture and guidance facilities are deleted from its SPG-55B radar. This is the Terrier Ordalt Program (TOP), providing the director with an improved servo subsystem and a new power drive for accurate slewing and acquisition.

◆ Mk 80/84/85 (MFCS)

The Polaris FCS is obsolete in the U.S. Navy.

Mk 84 was the Polaris A-3 missile-control system for *Lafayette*-class missile submarines, replaced by Poseidon fire control (Mk 88). British Polaris submarines are equipped with Mk 84

Mod 2 (Mod 1 was a version introduced to control the Mk 2 Mod 1 version of the missile-guidance system with the Mk 5 Mod 1 missile). Mk 84 uses Computer Group Mk 146.

Mk 85 was an abortive Polaris FCS for cruisers.

See also the entry for Polaris in the Strategic Strike Systems section.

♦ Mk 86 (GMFCS)

The Lockheed Mk 86 gun-and-missile fire-control system employs the SPQ-9 TWS radar, the SPG-60 tracker-illuminator, and an electro-optical sensor (closed circuit television or LLLTV). A laser range-finder can be mounted on the stabilized television camera platform or on the SPG-60 antenna, and bore-sighted to the television tracker. An IR sensor can be mounted over the television and laser range-finder to track multiple targets, detect gun flashes, and provide a passive image of the area around the ship. The 2 radars operate independently and are linked only by the computer. SPQ-9 provides surface search and low-altitude air coverage. SPG-60 automatically scans to acquire a target but can also provide horizon search. The system can accept data from other standard U.S. systems such as NTDS or ITAWDS (for amphibious fire support) or the Mk 74 MFCS, and Mk 86 can accept data from other shipboard sensors and from 1 of 4 target-data transmitters (TDTs).

Mk 86 grew out of an Operational Requirement issued in 1961 for a new surface-to-surface GFCS to support amphibious operations. BuOrd issued a contract to Lockheed Electronics in 1964. Mk 86 was required to track 4 targets and to engage 2, and also to be compatible with the variety of guns in the fleet (3-in to 8-in). It had to interface with NTDS. All of these requirements pointed toward the use of a general-purpose (programmable) digital computer. Mk 86 was tested in this surface-only form (as Mod 0) in 1965 on board the *Barry*, using only the SPQ-9 radar. About 1967 requirements for antiaircraft fire control and CWI (for missile control) were added, requiring a separate monopulse air-track antenna (SPG-60) with its transmitter and receiver. New versions introduced at this time were Mod

1 (surface and air gunnery) and Mod 2 (surface and air gunnery and CWI for missile control). The CWI mode could be used as a backup Tartar (now replaced by Standard Missile [MR]) control channel.

Mod 1 was for the *California* class (superseded by Mod 3). Mod 2 was for the test ship *Norton Sound*.

Because surface fire and AA fire used separate antennas, the modified Mk 86 could engage 2 targets simultaneously (it has 2 separate gun-control consoles). It used a more powerful computer, a Univac 1219 (Mk 152) in place of the Univac 1218 (Mk 150) of the original system. This doubled memory capacity (to 32k 18-bit words, with 16 I/O channels) and permitted simultaneous use of the fast and slow channels. Using the Mk 152 Mod 2 computer, Mk 86 could track 5 targets, engaging 2 simultaneously. Computing range was 131 kyd, maximum angular rate (air targets) was 12 deg/sec, maximum range rate (air) was Mach 3, required MTBF was 416 hr, and required MMTR was less than 18 min. In this form Mk 86 could communicate directly with NTDS and with the Tartar (now Standard Missile) system without special buffers.

Capabilities of the existing versions are:

	VERSIONS					
	Mod 3	Mod 4	Mod 5	Mod 8	Mod 9	Mod 10
Surface/low-fliers tracked	4	4	4	4	4	4
Air targets tracked	1	1	1	1	2	1
Simultaneous surface/low-flier engagements	2	3	2	2	2	2
Simultaneous air-target engagements	1	1	1	1	2	1
Semiactive illumination	No	No	Yes	Yes	No	No
Visual trackers	2	3	2	1	1	2

Versions:

Mod 1 was for the *California* class (superseded by Mod 3).

Mod 2 was for the test ship *Norton Sound*.

Mod 3 (*Spruance* and *California* classes) uses the Mk 152 computer.

Mod 4 is on board *Tarawa*-class assault ships.

Mod 5 is in the *Virginia* and *Kidd* classes; it uses a UYK-7 computer. Total weight is 14,200 lb.

Mod 6 is a version with a UYK-20 computer. Total weight is 11,734 lb.

Mod 7 is a Mod 0 with a new-generation computer (UYK-20). Total weight is 7200 lb.

Mod 8 was the version for modernized *Adams*-class destroyers; the program was canceled after the first 3 had been installed. Mk 86 did replace the earlier Mk 68 system on board the West German *Adams*-class destroyers, and a similar program is underway for the Australian ships of this type. The computer is UYK-7. Total weight is 14,750 lb. Fitted with a UYK-7, a Mk 86 can track up to 120 targets simultaneously.

Mod 9 is the version for Aegis ships. It has no SPG-60 radar, using Aegis data for gunfire control against air targets. The computer is UYK-7, and total weight is 10,000 lb.

Mod 10 is a replacement for Mod 3 with a UYK-7 computer, for *Spruance*-class destroyers; it was conceived partly as an adaptation of Mk 86 to fire laser-guided shells (Deadeye; see the discussion under the Mk 42 5-in/54 gun, below). The standard gun-control console was replaced by a Mk 113 weapons-control console, providing an interface between fuze-setting and func-

The 2 radars of the Mk 86 GFCS on board the USS *Mississippi*, June 1988: radome-enclosed SPQ-9A above, SPG-60 below. The hole in the SPG-60 antenna is for the television tracker. (Stefan Terzibaschitsch)

tion-setting, selecting ammunition, calculating ballistics for the guided shell, and designating the target to the Seafire laser designator. The computer is UYK-7, and total weight is 15,507 lb.

Mod 11 (1983) supersedes *Mod 4* in the *Tarawa* class; the computer is UYK-7. Total weight is 15,507 lb.

Mod 12 is a UYK-7 version for the *Kidd* and *Virginia* classes.

In November 1989 Lockheed Electronics delivered the first of a series of Ordalt kits developed under a 1985 contract, providing a digital MTI and a low-noise front end (LNFE) for the SPQ-9A radar. The LNFE is built around a solid-state low-noise amplifier; fitted with it, the radar can detect smaller targets at greater ranges. The FY90 program includes improvements to SPQ-9A so that it can detect small radar targets more effectively, in response to requests by the Middle East Force. Presumably, the LNFE was intended primarily to deal with air targets; the new program concerns small attack boats such as Boghammers.

The FY88 program also included an emergency improvement to the Mk 86 system to engage fast, radically maneuvering surface targets (such as Boghammers), which were then being encountered by the Middle East Force.

Current SPG-60 improvement programs include a sidelobe canceler (to solve problems recently experienced by the fleet), a product improvement package for greater effectiveness against sea-skimmers (FY90), and addition of a CW injector so that the radar can function as a second track/illuminate channel for NATO Sea Sparrow missiles on board *Spruance*-class destroyers and large amphibious and auxiliary ships (FY90).

Conversion of Mk 86 systems on board U.S. cruisers to the UYK-43 computer began in FY88.

Under the FY91 program, the Mk 86 Video Processor Mk 2 is being improved to provide false-alarm filtering, adaptable video thresholds, a capability to track 10 or more targets, and also full-range Low-Altitude Detection/Acquisition (LAD/A) coverage.

◆ Mk 88/89

Mk 88 is the Poseidon C-3 strategic-missile FCS. Mk 89 is the corresponding land test-facility FCS.

See the entry for Poseidon in the Strategic Strike Systems section.

◆ Mk 91

Band: X **Peak Power:** 2 kW (average, CW)

Antenna Dimensions: 100 × 96 in **Antenna Weight:** 3315 lb

Mark 91 is the U.S. FCS associated with the NATO Sea Sparrow Missile System (NSSMS). Mk 91 succeeded BPDMS (Mk

NATO Sea Sparrow on board the Norwegian frigate *Narvik*, March 1985, showing the radar of the Mk 91 fire-control system atop the raised platform at the left, and the 8-cell box launcher below and abaft it. The gun is an enclosed version of the standard U.S. twin 3-in/50, and the containers hold Penguin antiship missiles. (L. Van Ginderen)

115) and, like the earlier system, uses separate transmitting and receiving CW antennas. Targets are automatically designated from either SPS-58/65 or TAS Mk 23 radars, the Mk 95 radar of the Mk 91 FCS tracking the target automatically and illuminating it. Unlike BPDMS, NSSMS incorporates a wide-beam antenna to provide the missile with a reference beam. That reference in turn makes it possible for the missile to use proportional navigation, which is more efficient than a direct pursuit path.

Both transmit and receive antennas are 39 in in diameter; the transmitter is a parabolic dish, the receiver a Cassegrain twist reflector.

Mod 0 is the single version, *Mod 1* the dual version as used by the Danish, Norwegian, Italian, Japanese, and U.S. navies. There is also a special "Netherlands" configuration used by the Belgian, West German, Dutch, and Spanish navies employing the Dutch M25 fire-control system.

NATO Sea Sparrow launchers and Mk 91 illuminators (radar Mk 95) on board the carrier *USS Ranger*, July 1986. An electro-optical tracker is located between the 2 radomes of the radar illuminator-tracker. (Hughes)

◆ Mk 92 and Mk 94

Band: X **Antenna Dimensions:** (search) (track) 96-in diameter

Antenna Weight: 6300 lb (topside weight)

Mk 92 is a U.S. version (produced by Sperry) of the Dutch Signaal WM 28 fire-control system. The associated TWS radar, which employs 2 antennas (the combined antenna system [CAS], UD 401) inside an egg-shaped radome, has no separate designation and is, therefore, described here. As installed on board *Perry*-class missile frigates, Mk 92 controls both the designator in the egg and a separate tracker/illuminator, the STIR (UD 417). Mk 92 controls both Standard Missiles (SM-1) and a 76-mm gun. As installed on board *Pegasus*-class missile hydrofoils, the Mk 92 is limited to the CAS and controls only a 76-mm gun.

The single console (weapons-control console Mk 106) provides a PPI for tactical display and 2 track displays (A- and B-scopes). Tracks are designated by means of a ball on the console, an acquisition gate being placed around the target blip on an A-scope. Once the target is being tracked, the A-scope displays engagement limits around the target blip so that the operator can gauge when to engage. The time-shared B-scope indicates designation or track error by the position of the target blip relative to the scope's center. Maximum instrumented range on the PPI is 128 nm (on the A-scope, 64 nm).

Versions:

- Mod 0*: 1 air-engagement channel, 2 TWS surface channels, missile and gun control; 1905 lb topside/9086 lb below decks.
- Mod 1*: 1 air-engagement channel, 2 TWS surface channels, guns only, for *Pegasus*-class PHM and *Bear*- and *Hamilton*-class coast guard cutters; 1905/5637 lb. *Mod 5* (Saudi PCC/PCG) is similar.

The antennas inside the Mk 92 Combined Antenna System (CAS). (Sperry)

- Mod 2: 2 air-engagement channels (i.e., 1 STIR), 2 TWS surface channels, missile and gun control; 6318/15,848 lb. This version is installed in the *Perry* class and requires a separate Mk 107 console, incorporating a PPI, for STIR control. Existing Mod 2s were subject to a "near term improvement" program when ships were equipped with SM-1 Block 6 missiles. The test ship was the *Stephen W. Groves* (1983).
- Mod 3 is a proposed version, not as yet sold, Mod 6 without the STIR.
- Mod 4 was not used as an official designation. It may have been the abortive Phase III with the phased-array radar.
- Mod 5 Version for the Saudi PCG and PCC programs, similar to Mod 1 above but with a higher proportion of American-made parts. There are also about 15 design improvements enhancing safety, reliability, and maintainability. Total weight is about 7835 lb.
- Mod 6 CORT upgrade, see below. In this version the Mk 106 Mod 1 weapons-control console is replaced by Mod 2, and the Mk 107 STIR-control console is replaced by Mk 107 Mod 1. Total weight is about 24,000 lb.

All versions use the UYK-7 computer, which replaces the Mk 159 (a Signaal computer) of the Mk 94 prototype system (an imported WM 28). In Mod 2 and Mod 6, CWI (for missile control) is available on 2 channels (using SPG-51D transmitters), in both the "egg" and in the separate STIR. The Mod 2 version of the system includes an OJ-194(V)/UYA-4 PPI display (not in Mod 1) plus consoles Mk 106 and Mk 107. The Mk 106 console is the system control center, with displays for target detection, acquisition, and tracking, as well as controls for target assignment, selection, weapons utilization, and means for data entry. The displays show IFF returns. In Mod 2 the console displays firing channels 1, 4, and 5. The Mk 107 STIR console is similar to Mk 106 except that surface track-and-search controls have been eliminated; it carries displays for detection, acquisition, and tracking of air targets by the STIR, as well as controls for

target assignment, target selection, and weapons utilization. Both of the air channels (2 and 3) are controlled from the Mk 107.

The 2 CAS antennas, a search antenna below and a tracker above, share a common feed and time-share their power. The search antenna scans at 60 rpm, a rate rapid enough to allow for TWS tracking of up to 2 surface targets. The search antenna provides a measure of height-finding, by spiraling the beam up in 3 revolutions (4 beamwidths), then down again in half a revolution, for interlaced coverage.

The parabolic dish at the top of the egg is used for 3D (i.e., air) target acquisition and monopulse track. Like the search antenna below, the parabolic dish can track up to 2 air targets while searching for more. This array is designated Mk 53.

The 100-in-diameter STIR antenna tracks targets out to greater ranges. It employs a modified Mk 39 antenna, with a monopulse cluster and CWI fill-in horns, on an SPG-60 pedestal. The STIR antenna is designated Mk 54.

Mod 1 is the version on board the hydrofoils, controlling only a 3-in gun. Mod 2 is on board *Perry*-class frigates. Mod 5 is mounted on board Saudi PCG- and PCC-class gunboats built in the United States.

Mk 94 was the functional prototype, an imported HSA system. It has a Mk 159 computer; Mk 92 has a UYK-7.

Several improved versions of the basic Mk 92 have been proposed. Phase I is a near-term get-well program, and it is being carried out. Phase II adds a new coherent receive/transmit (CORT) transceiver to counter heavy jamming, clutter, and STA clutter (i.e., targets just beyond instrumented range that are so large that their STAEs swamp echoes from small nearby targets). CORT is, unfortunately, quite massive, and it is not likely to be very widely applied. As of 1988, the U.S. Navy planned to buy 6 sets of CORT electronics. The *Ingraham* (FFG 61), the last of the *Perry* class, has a unique combat system combining CORT with an IADT. Phase III, proposed by Sperry (now UNISYS), is a much more ambitious program, adding a new high-elevation array. Phase III is intended to counter high-altitude targets in a heavy jamming environment. The navy has argued that Phase III is too expensive and too massive for ships that are already almost overloaded. Congress kept the program alive, but as of 1988 it had been canceled.

The Engineering Development Model (EDM) of the coherent receiver-transmitter was tested on board the *Estocin* in November 1986, and production of hardware was authorized in August 1987. The EDM was removed from the ship and installed at the combat-system test center in January 1987; integration testing was completed in October 1988. The upgraded Mk 92 with a production CORT was scheduled (early in 1988) for tests at sea on board the *Ingraham* in the third quarter of FY90. She has the SYS-2(V)2 IADT and an SPS-49(V)5 radar. The FY88 program included studies of how CORT might be backfit into ships lacking these systems.

As of 1990, UNISYS claims that CORT doubles the detection and tracking range of the Mk 92 system within the same space and weight. The radar can acquire and track targets with a radar cross section only 10% that of the smallest that Mod 2 can acquire and track. In addition, new components double system MTBF. The first ship to be retrofitted (to be completed in the spring of 1991) is the *Taylor* (FFG 50), to be followed by batches of 4 ships per year, beginning in FY92. Besides the *Ingraham*, 5 CORT upgrades were funded in FY88 (FFG 50, 51, 53, 55, and 56) and 3 in FY90. The upgrade includes replacement of the existing UYK-7 and UYK-20 computers by UYK-43s and -44s, and installation of SQQ-89 (full-spectrum towed-array processing). Spain and Taiwan have bought the CORT upgrade package (ORDALT 15-535) for their *Perry*-class frigates (in the Spanish case, only for the last 2 ships in the class).

◆ Mk 93 (GFCS)

The Honeywell gunfire-control system of the CPIC-prototype export coastal-attack boat is associated with the EX-74 (Emerlec-30) gun and uses Kollmorgen's Mk 35 periscope director.

This system appears in modified form on board other small combatants built for foreign navies, armed with the Emerlec-30 and using the periscope director. The radar is a Litton LN-66HP, a lightweight computer permitting 2-target TWS operation. The optical director can provide 2 more target tracks. The lightweight (1100-lb) computer can handle ballistics for 20-mm through 76-mm calibers.

EX-93 was the progenitor of the Honeywell/Hughes H930 series (hence the latter's name). Two somewhat similar systems were developed, Kollmorgen's Sea Serpent and the Westinghouse W-1200. Sea Serpent combined its optronic periscope director with a navigational radar (in this case a Raytheon Pathfinder) and a UYK-19 computer. Up to 20 targets could be tracked (TWS), and the laser mounted with the director optics provided accurate range data. Westinghouse combined the periscope director (Mk 35) with an LN-66HP radar and a UYK-19 computer. It also developed a series of progressively more powerful versions. Both seem to have originated in the mid-1970s, required for a system for Ethiopia. Honeywell won the contract (for H930 Mod 0), but the company's CEO decided to reject the system (a fortunate decision since Ethiopia soon had an anti-Western revolution). It seems likely that Kollmorgen and Westinghouse developed their own systems partly to compete for this particular contract; both were announced in the late 1970s.

◆ Mk 98 (MFCS)

Mk 98 is the Trident FCS for *Ohio*-class submarines (Mk 88 Mod 2 is Trident C-4 on board earlier submarines). Mod 0 is for Trident I. Mod 1 is for Trident II (D-5 missile). Mod 2 (identical to Mod 1 except that it controls 16 rather than 24 missiles) is the British version, and Mod 3 is the land-based test version.

◆ Mk 99 (MFCS)

Mk 99 is the Aegis AAW FCS. The Aegis system as a whole is designated Weapons System Mk 7. Versions:

Mod 0 is the 2-illuminator test version built for the *Norton Sound*, using separate guidance (Mk 90) and tracking (Mk 91) radar sets with 2 standby illuminators. (1970)

Mod 1 is the prototype production version for the *Ticonderoga*, using SPG-62 illuminator-only radars. The corresponding Aegis version was Mod 3.

Mod 2 is the production version for the *Ticonderoga* class (Aegis Mod 4).

Mod 3 is for Aegis Mod 6, using SPG-62A radars (1985); it was a test configuration on board the *Norton Sound*.

Mod 4 is for Aegis Mod 7; it is similar to Mod 3 but has 4 SPG-62As.

◆ Mk 100-114

Mks 100-114 are ASW fire-control systems.

◆ Mk 115

Band: X

Antenna Dimensions: total 79 × 84 in (including pedestal)

Antenna Weight: 1800 lb

Mark 115 is the FCS associated with the Basic Point-Defense Missile System (Sea Sparrow); at this writing BPDMS installations are being replaced by Phalanx close-in defensive guns and also by NATO Sea Sparrow missile systems. Because the associated radars have no separate designations, they are described here.

Fire is controlled from the CIC, where a fire-control panel monitors the system. The operator there turns on launcher and radar and selects and fires the missiles. Interception range is described as 4+ nm.

The missile homes on CW energy, so the radar cannot employ a single antenna to receive and to transmit. The Mk 33 transmitter is a 2-ft parabolic dish. The Mk 19 receiving antenna is

Sea Sparrow Basic Point-Defense Missile System handlebar director (Mk 115), with its missile launching. (U.S. Navy)

a 2-ft planar array using 52 slotted waveguides in 4 sections, and is electronically conically scanned to track a target.

Tracking is manual: errors detected by comparison of transmitted and received signals are displayed in a gunsight atop the modified director pedestal, and the operator moves the "handlebars" to keep the error signal centered in the optical display. Manual pointing was adopted because the targets were expected to have high closing velocities but little angular motion relative to the ship being attacked. Even so, the person in the loop makes for a relatively long reaction time.

Work on this system began in 1963, and production began in 1967. The Mark number is higher than that of the later NATO Sea Sparrow System (Mk 91) because this quick-development system was inserted into the series numbered Mk 100 and above that is otherwise restricted to underwater fire-control systems.

◆ Mk 116-119

Mks 116-119 are ASW fire-control systems.

◆ Weapons Direction Systems (WDS)/Target Designation Systems (TDS)

Weapons Direction Systems mediate between CIC and the missile fire-control system. They are all outgrowths of post-World War II work on automatic and semiautomatic Threat Evaluation and Weapon Assignment (TEWA) systems; the TEWA was needed to decide, very rapidly, whether a given target could be or should be engaged, i.e., to take into account the effective engagement capabilities of the weapons on board the ship. A ship's actual target-handling capacity depends on the capacity of her WDS, since directors are cued, not directly from CIC, but rather from the series of tracks held by the WDS, itself fed by the same radars feeding CIC. Only with the advent of NTDS is the WDS fed directly from the automated track file in CIC, since in earlier nonautomated ships the grease-pencil track data in CIC are not accurate enough for such assignment. Thus, the difference in target capacity between an NTDS ship and a non-NTDS ship is enormous, the pre-NTDS ship being limited to perhaps 4 or 8 targets. This limitation is entirely separate from the limitation imposed by the number of missile directors, i.e., of fire-control channels. Once a particular fire-control channel has completed its engagement with a particular target, it obtains its next target, not directly from CIC, but rather from the WDS.

Non-NTDS ships with computer-driven combat systems, such as the *Perry*-class FFG, are equivalent to NTDS ships in this sense: they can maintain very large numbers of tracks ready for designation to fire control. Precomputer ships must generally assign a tracking console to each target, and the number of such consoles is very limited. As in NTDS, tracking on each console is rate aided; but the consoles do not communicate, and each carries only a single track. The pre-NTDS missile systems in current U.S. service are on board *C. F. Adams*-class missile destroyers.

A WDS consists of a designation system (which takes target information from CIC, maintains a series of target tracks, and assigns targets to FCSs and launchers) and the associated auxiliary components, mainly optical target-designation transmitters (TDTs) and 1 or more casualty weapons-direction and firing panels. In some cases the WDS also includes a separate coordinate converter with its associated computer. Early missile WDSs were built around Designation Equipment (DE), which was superseded by Weapons-Direction Equipment (WDE). WDS fully integrated with NTDS needs no separate DE or WDE since the enveloping NTDS holds all the potential target tracks.

All of the WDS systems are outgrowths of a series of automated target-designation systems conceived by Bell Laboratories in 1945-47 under a Bureau of Ordnance project, FCS Mk 65, intended to deal with future fast jet aircraft. The reader may sense a certain convergence between Mk 65 and NTDS; the latter, however, was a Bureau of Ships project. One might see Aegis as the final merger between NTDS and WDS. Bell's major contribution was to see that some form of TEWA and some form of accurate tracking were needed to mediate between search and fire-control radars. The original concept, then, was to provide a highly accurate short-range air-search radar (SPS-3) for mediation, together with an ATEWA. In fact SPS-3 failed, but SPS-39 was conceived as the replacement.

The earliest Bell-type system, Target Designation System (TDS) Mk 3, was installed on board the command cruiser *Northampton*. The TDS series also included a much simpler category of equipment, intended to permit a CIC to designate directly from search radar to gun directors. These TDSs were the electronic equivalents of optical target data transmitters (TDTs) used by an officer to assign a visible target to a director. Until the end of the Korean War, targets were typically designated from CIC by sound-powered phone, the radar in the director finding its target by searching around the location reported by CIC. However, as aircraft speeds increased, this system no longer sufficed, and more direct means of transferring data directly from CIC to director were required.

The chief systems in service by the mid-1950s, some of which probably survive on board ex-U.S. warships in foreign navies, were TDS Mk 5, 6, and 7. Mk 5 was designed for destroyers, Mk 6 for carriers, and Mk 7 for missile cruisers. Mk 5 employs a horizontal PPI with 4 joysticks, for a supervisor and 3 designators. The PPI is a PPI repeater (actually a television), and the joysticks move 4 designating hooks (semicircles on the screen). They transmit designations to the directors, which provide repeat-back hooks to show the directors' own positions. The horizontal display can also be used for grease-pencil marking (e.g., to enter nonradar data, such as lookouts' reports). The designator who hooks a target tracks it manually (with the joystick) until it is picked up by the director.

The PPI is, in effect, an integrated tactical display (albeit of only 1 search radar), and in this case threat evaluation is entirely manual. In such systems, maximum displayed range is generally 30 nm (60 kyd). Although the system as such does not impose any limit on target velocity, clearly it cannot easily serve as a link to the directors if the targets are very fast, as in that case they cannot easily be manually tracked, no matter how good the joystick operator.

There was also a rather more ambitious TDS Mk 1 on board the frigates (actually large destroyers) of the *Norfolk* and *Mitscher* classes, and on board contemporary destroyers converted for ASW (*Basilone* and converted *Fletcher* classes). These TDSs were essentially manual target-designation switchboards, capable of tracking 2-3 targets simultaneously and of controlling 2-8 directors. Mk 1 could not assign weapons to targets.

TDS Mk 3 was the first U.S. automatic target tracker, handling twice as many targets as directors, automatically tracking all of them (in an early application of TWS), and automatically evaluating the threat each target presented. Directors and guns were assigned automatically. The entire system weighed 23,905 lb in its 4-director installation on board USS *Northampton*. Mk 3 included an integrated target display and could

deal with target ranges as great as 30 nm (60 kyd). TDS Mk 3 is worth describing here because it was the basis for subsequent forms of WDS. An evolved version, TDS Mk 7, was installed on board the first 2 U.S. missile ships, the cruisers *Boston* and *Canberra*.

It turned out that the automatic TEWA system incorporated in TDS Mk 3 was impractical. The later WDSs descended from Mk 3 all used manual threat evaluation, which generally meant the operator would decide which target would enter engagement range first. Only when the WDS was integrated with the powerful computer of the NTDS system could threats be evaluated automatically.

WDSs:

Mk 1 System for the first U.S. missile ships (*Boston* class), built around DE Mk 7 (GMFCS Mk 71).

Mk 2 System for light cruisers converted to Talos ships, now extinct. Mod 0 was in CLGs 3 and 4, Mod 1 in CLG 5. Mk 2 used DE Mk 8-0.

Mk 3 Terrier system. Mod 0 was for the first 4 *Farragut*-class missile destroyers, with Mk 73 FCS. The designation equipment was Mk 9-0. Mod 1 was in light cruisers converted to Terrier ships, now extinct (FCS Mk 73). Mod 2 (with DE Mk 9-1) was the version for *Farragut* (DDG 37)-class destroyers equipped with FCS Mk 76. It used DE Mk 9-1. An unusual feature of this version was that the 2 visual target-designation transmitters Mk 24 could be used to reassign missile directors already tracking other targets without intervention at the radar console. At least in this version the WDS could interchange information between the underwater FCS and the missile-tracking radars; the radars could be used to track outgoing ASROC missiles and thus to correct for the effects of the wind. In this mode the sonar target's position could be displayed at the DE Mk 9, and a director was assigned to track the outgoing ASROC to its point of water entry. This WDS was also in the *Leahy* class.

Mk 4 Tartar system for *C. F. Adams*-class missile destroyers and *Brooke*-class frigates. Mod 0 is in DDGs 2-14 (WDE Mk 1-0), Mod 1 in DDGs 15-24 (WDE Mk 1-1) and the Italian *Audace* class, Mod 2 in the FFG 6 class (WDE Mk 1-2), Mod 4 in DDGs 35-36 (WDE Mk 1-7), and Mod 5 in DDGs 31-34 (WDE Mk 1-7) and the Spanish *Baleares* class. Mk 4 is also the system in the Italian *Impavido* class and in the Japanese *Amatsukaze*-class destroyers. Mk 4 was deleted from French and German missile destroyers when they were fitted with automated CDSs not quite equivalent to NTDS (the Germans and Italians developed their own equivalents to WDS Mk 13). Ships fitted with NTDS had their Mk 4 analog systems replaced by the digital Mk 13.

Mk 5 Terrier system for carriers, now extinct. Mod 0 was in the *Kitty Hawks* (WDE Mk 3-0), Mod 1 in the *America* (WDE Mk 4-2).

Mk 6 Cruiser system for the *Long Beach* (Talos/Terrier) and *Albany* class (Talos/Tartar), with WDE Mk 2 (Mod 0 in the *Long Beach*; Mods 1, 2, 3 in the *Albany* class, now extinct). When the *Albany* was rebuilt with NTDS, she could carry 128 tracks, compared to 24 with her previous WDE.

Mk 7 System for Terrier (SM-1(ER)) cruisers (replaced by Mk 11). Mod 0 (WDE Mk 4-0) was in the *Bainbridge* before her modernization with NTDS. Mod 1 (*Leahy* class, with WDE Mk 4-1 rather than Mk 4-0) increased the value of the range scales, doubling the range to conform to SPG-55B rather than -55A. Estimated weight is 17,500 lb. Mod 2 is a digital system, connected to NTDS via the converter SYA-3. Mod 3 is in the *Belknap* class (WDE Mk 8-1).

Mk 8 Terrier/SM-1 system, roughly equivalent to Mk 3 and 4.

Mk 9 Projected Typhon system, canceled.

Mk 10 Projected system for later heavy missile cruisers (CG 13 class), canceled.

Mk 11 WDS designed for integration with NTDS in a missile cruiser carrying SM-1(ER). Typically, a target is detected by a detector/tracker in NTDS, who enters the track into the computer. A separate identification operator decides that the track is hostile, and it is then passed to a track supervisor, who makes sure that the rate-aided tracker stays on the blip. The ship's weapons-systems coordinator (SWC) decides that fleet aircraft cannot intercept and, thus, that the target must be handled by the ship's missile system. The SWC alerts the ship's FCS and at the same time passes the target to a special tracker, who refines target position by using an expanded (4-nm) scale on the PPI. The tracker in turn passes the target to an FCS coordinator, who passes it to a particular FCS. At this stage a missile and launcher are selected. The FCS and launcher feed back to the FCS coordinator and the associated engagement controller. There are 4 consoles: OJ-166 FCS, OJ-167 for the launch system, OJ-194 PPI, and the Mk 80 system casualty. Mod 0 is in the *Belknap* class (CGs 28-34 as completed); Mod 1, the *Truxtun*; Mod 2, the *Leahy* (CG 16) class and the *Bainbridge*; Mod 3, the *California* class; Mod 4, the modernized *Farragut* (DDG 37) class.

Mk 12 System for Aegis (part of the overall Aegis weapons system). Mk 12 schedules and controls the firing of SM-2 missiles, computes missile orders, and schedules target illumination. It determines whether a given target can be intercepted, schedules assignments, and solves fire-control problems. The WDS communicates directly with the Mk 26 launcher in digital format for the first time in a U.S. Navy system.

Mk 13 System for Tartar (SM-1(MR)) ships with NTDS (GMFCS Mk 74 Mod 6). Mod 0 is in the *Virginia* and the *Kidd* class; Mod 1, the *Adams* class, as modernized with JPTDS (DDs 9, 12, 15, and 21); Mod 2, the *Perry* class; Mod 3, the *Adams* class modernization (as projected in 1977: DDG 17 would have been the prototype but was not done); and Mod 4, the *Adams* class modernization (DDGs 19, 20, and 22) and modernized Australian *Adams*-class destroyers. Consoles: 2 OJ-194(V)3 PPIs, Mk 90 or 91 launch-system console, Mk 218 casualty weapons-director panel, and Mk 129 casualty battery-control unit. There is no launch-system console in the *Perry*-class version.

Mk 14 System for Terrier ships with NTU, beginning with the *Mahan* in 1979. This system is unique in being able to handle both (MR) and (ER) missiles. It incorporates 2 UYK-20A or -44 computers and 2 or 3 OJ-194(V)4 consoles. Mod 2 is Terrier NTU. Mod 3 is for the *Long Beach* and the *Leahy* class. Mod 4 is for missile cruisers. Mod 5 is for missile destroyers.

Designation Equipment:

Mk 4 Part of TDS Mk 4. Maximum range is 60 kyd, and it is capable of tracking 4 targets (manual designation, estimated elevation). Total weight of the Mod 2 version is 2080 lb (TDS Mk 4-2 weighs 3845 lb).

Mk 5 Part of TDS Mk 5. Maximum range is 60 kyd, and it is capable of tracking 4 targets (manual designation, estimated elevation). Total weight of the Mod 1 version is 660 lb (TDS Mk 5-7 weighs 2100 lb).

Mk 6 Part of TDS Mk 6. Maximum range is 60 kyd (maximum range displayed is 240 nm); 4 targets are tracked simultaneously (joystick tracking, estimated elevation). Mk 6 controls 8 directors, weighs 6640 lb (TDS Mk 6-0, 9200 lb), and has 4 operators.

Mk 7 Part of WDS Mk 1-0 of the *Boston*-class missile cruisers (now extinct). Mk 7 weighed 45,000 lb (out of 51,470 lb for the WDS) and required 24 operators in the WCS, 1 in CIC, and 10 in the AA station. Maximum range was 120 kyd. DE Mk 7-0, on board the *Boston* class, was the predecessor of the later Mk 8 and Mk 9 on board Terrier and Tartar ships. Like its successors, Mk 7 divided the weapons-assignment task into 3 phases: display/detection/tracking, evaluation/FCS assignment, and reevaluation/weapons assignment. There were 6 target-tracking consoles Mk 17-0, each equipped with a PPI and a pantograph

by means of which the operator could enter the coordinates of a point on the screen. Normally 2 consoles were assigned to the ship's missile battery and 4 to her guns. The operator at a console could enter a target into 1 of 16 TWS channels (i.e., into 1 of 16 channels that would project ahead the position of a range-gated target). Later, less ambitious designation equipment used rate-aided tracking, in which the system projected ahead by assuming that the target did not maneuver, and an operator monitored that projection to correct for maneuvers. Targets were tracked in 3D. Each Mk 17 console provided only range and bearing, but target elevation could be displayed and inserted at 1 of 2 Mk 16 consoles. Mk 16 showed elevation for any or all of the TWS channels; the operator positioned a cursor, and the height-finding radar then automatically tracked in altitude. This complication was deleted from later systems, which provided a very limited altitude display at the left-hand side of their target-tracking consoles. There were separate consoles (Mk 21) to accept target data from target-bearing transmitters, comparing their assignments to radar data. For the second phase, the TWS channels fed into a target-assessment console Mk 18, and 3 director-assignment consoles (2 Mk 21s for gunnery, 1 Mk 23 for missiles). The Mk 18 could display all 16 channels, and its operator could select those targets of particular missile interest, in effect editing the displays of the director-assignment consoles. The missile-director-assignment console had 2 displays side by side, a synthetic PPI picture of the missile-engagement channels alongside a series of electronically generated bar graphs to indicate target suitability and urgency. Finally, for Phase 3 there were a weapons-assignment console (Mk 22) and launcher-status consoles (Mk 19).

Mk 8 Part of WDS Mk 2-0 (converted cruiser system). Maximum displayed range is 240 nm, and maximum designation range is 300 kyd; Mk 8 handles 6 targets simultaneously. Weight is 9160 lb out of a total of 11,300 lb for the WDS. There are 18 operators in the WCS, 3 in CIC, and 4 in the AA Station. Mod 0 was Mk 6 modified for target evaluation, designation, and control for Talos missiles (now extinct). Mods 1 and 2 were versions for converted U.S. cruisers, now extinct. Mod 3 is the Terrier system on board the Italian cruiser *Vittorio Veneto*. The Mod 0 version could engage up to 6 raids. There were 2 plotter repeater loops, with stations in CIC and the WCS for raid identification and plotting; 1 loop was for long-range targets, the other for short-range targets. There was also a designation indicator to display raid positions, director positions, ship's heading, clear areas, and an indication of when the assigned director was at the designated position. Basic raid information, special (nuclear) threat warning, and missile-warhead-type (conventional/nuclear) recommendations were sent electronically by CIC to the WCS via the 2 plotter loops. The CIC operators wrote in the raid-identification letters adjacent to the radar pips they chose, and this written-in video was transmitted to the WCS; the appropriate WCS plotter-repeater operators copied the plotted information and began tracking. The WCS-plotted information appeared on the main WCS display and was repeated to CIC via the loops so that CIC could monitor the progress of the plotting. The main display in the WCS was a pair of 16-in vertical CRTs (Designation Indicator Mk 5), each operating at either a 60- or a 240-kyd range scale, showing radar video, written-in data, designator symbols, and director repeat-back numerals. Overlays could be rotated to show either ship's course or a trial course-change proposed at the WCS control panel. The main console in WCS could assign raids to a pair of target-engagement consoles that could track targets, designate raids to the radar directors, and compute missile-intercept points. This system incorporated a separate elevation-tracking console (Mk 46, with three 7-in CRTs with E-type displays, showing elevation angle on a vertical scale). The other consoles were director assignment (Mk 42, with a 12-in CRT) and target entry (Mk 44, with two 12-in dual-gun CRTs for long- and short-range air-search radar video, and one 5-in expanded-offset display). WDS Mk 2-1 (using DE Mk 8) controlled Talos and Tartar batteries for the converted

Albany-class cruisers. In this version the elevation console Mk 46 had an additional CRT so that the system could handle 8 rather than 6 target channels.

Mk 9 Part of WDS Mk 3-1. Maximum range was 120 kyd. There were 10 operators in the WCS, 1 in CIC, and 10 in the AA Station. Mk 9 was the forerunner of WDE Mk 1, 3, and 4 (for the *Adams* class, the converted light cruisers, the *Leahy* class, and the *Bainbridge*). Up to 6 targets could be selected, manually rate-aided, and tracked. They could be evaluated and designated to either guns or missiles. The operator at a console in CIC assigned targets to 1 of the 6 channels by moving a pantograph over the target blip on the PPI, then pushing a button. The system could also store a standard keep-out range (the range at which the incoming target could be assumed to be releasing its weapon), and the value of this range could be varied from target to target. Once a target had been selected, it could be tracked with rate-aiding by 1 of 2 similar consoles in the WCS. The track channel developed and stored target velocities based on successive position corrections introduced by the tracker in the WCS. Each console operator was expected to track 3 targets in 3D (i.e., to correct the rate-aided track in both PPI and height, the latter as shown on the left-hand edge of the CRT). Targets were evaluated and assigned to directors at a pair of director-assignment consoles, each carrying both a synthetic-video CRT and an electronic graph (target speed, height, time remaining for engagement, remaining busy time for track radars currently engaged). Mod 2 is in the Italian *Doria*-class cruisers.

Weapons-Direction Equipment (WDE):

Mk 1-0 Tartar (later SM-1(MR)) WDE for *Adams*-class destroyers, used to select hostile targets and assign missiles and guns to the most threatening among them. Mk 1-0 is based on the earlier DE Mk 9. Up to 6 targets can be selected for engagement, manually rate-aided, and tracked. They can be prioritized. As in contemporary systems, there are 2 target-selection and -tracking consoles Mk 37-0, 1 director-assignment console Mk 47-0, and 1 weapons-assignment console Mk 48-0. All are located in CIC. Raw video from 1 of the 2 search radars (2D and 3D) appears on 1 of the Mk 37s, and each target is input into a channel by means of a pantograph. Once a target has been entered into a channel, further tracking is the responsibility of 1 of the 2 Mk 37 operators, each of whom is expected to track 3 targets (however, each may be responsible for all 6). Height is displayed at the left edge of the PPI for tracking in 3D. If height information is not available, the fire-control radar itself (SPG-51) searches in elevation to acquire a target. The Mk 47 console shows a PPI on its left and a multipurpose plot (electronic graph) on its right; the PPI shows synthetic video (generated by the system's Mk 118 computer) for all 6 targets being tracked so that the console operator can compare them. It also displays the ship's track and the missile system's blind zone; it can display the velocity vector of any 1 of the 6 targets. The graph shows target speed, target height, time interval for missile-director assignment (assignments resulting in earliest and latest intercepts), and remaining busy time for MFCSs currently assigned. The console operator uses these data to assign fire-control channels; the computer slews the 2 directors in response and performs an acquisition search. The remaining console is used to assign the launcher to the highest-priority target; the operator is responsible for the final evaluation of the blind zones and of the range, altitude, and seeker-angle limitations of the missile. The operator actually fires the missiles.

Other versions of Mk 1 were

Mod 3: version for the Italian destroyers *Impavido* and *Intrepido* (1962)

Mod 4: projected version for the carrier *John F. Kennedy*, superseded by NTDS

Mod 5: projected version for Canadian frigates (1965), abandoned when Tartar was deleted from these ships

Mod 6: version for the *Mitscher* class's refit as DDGs, replaced by Mod 7 for these ships and also for the *Forrest Sherman*-class conversions

Mod 7: version for destroyers converted to missile ships, now extinct

Mod 8: Mod 1 integrated with NTDS.

Mk 2 Dual-purpose WDE to control both long-range (Talos) and short-range (Tartar or Terrier) missiles, in the *Long Beach* and the converted *Albany*-class cruisers. The *Long Beach* had the Mod 0 version, with 15 manned consoles. Targets were transmitted to the system via a target-entry console (Mk 44-0) in CIC. It carried 2 side-by-side radar PPIs (1 for long range, 1 for short), plus a third display to show a magnified portion of either radar's picture; NTDS data were superimposed on the radar video. There were 24 target-tracking channels. As in NTDS, the operator used a joystick to hook a radar pip and thus to insert a target into 1 of the channels. The system had 6 target-tracking consoles (Mk 45 Mod 0), each with 4 displays so that all 24 channels could be displayed simultaneously. Operators at the displays used their joysticks to enter tracking errors. Two elevation consoles (Mk 46 Mod 0) were used to track targets in elevation; each had 3 displays, which were time-shared among the 24 channels. Time-sharing was interrupted when a particular channel was assigned to an FCS. Operation was supervised by a second Mk 44 Mod 0 console manned by the tracking supervisor (e.g., to resolve crossing targets or to reassign unevenly distributed targets). Targets were assigned to directors by a pair of consoles (1 for Talos, 1 for Tartar or Terrier), each with a pair of displays (PPI and electronic bar graph). Finally, there were 3 launcher-assignment consoles (2 Terrier, 1 Talos in the *Long Beach*). The *Albany* class's version, Mk 2 Mod 1, was similar but with Mod 1 consoles. It was not embedded within NTDS.

Mk 4-0 WDE for the *Leahy* class, superseded when these ships were fitted with NTDS. Mod 1 had different scale overlays to accommodate the longer-range SPG-55B radar. Mod 3 was Mod 1 modified to receive digital input from an SPS-48 radar, using height-tracking console Mk 70-0. This console had two 4-gun CRTs, each of which showed gated (range and azimuth) height information for the targets assigned to the track channels, for a total of 8 channels (1964).

Mk 6-0 WDE for the abortive Typhon ships (WDS 9-0), (MR) and (LR).

Mk 7-0 WDE for the projected CG 13. It could track up to 24 targets.

Mk 8-1 WDE for WDS Mk 7-3 in the first 2 *Belknap*-class cruisers; superseded when they were converted to NTDS.

◆ Sharpshooter

Lockheed Electronics's on-mount digital-radar FCS for 20–40-mm guns was announced in 1974 and incorporated in the Spanish Meroka close-in weapons system. Sharpshooter embodies some Mk 86 FCS technology. This system was offered in 4 versions: Mk 1 (on-mount, as in Meroka), Mk 2 (off-mount, with stabilized optical sight), Mk 3 Mod 0 (off-mount, with television tracker but without an optical sight, and with dedicated tracking radar), and Mk 3 Mod 1 (off-mount, with television tracker combined with its stabilized optical sight, but without a dedicated tracking radar).

The X-band pulse-doppler monopulse radar is a developed version of the range-only radar used in the U.S. Army Vulcan system, but with greatly improved clutter rejection (and with tracking capability). There is also a stabilized optical sight with zoom magnification, slaved to the radar; and the control panel has 2 handgrips (1 for mode control—local/remote track, the other with the firing trigger and joystick). The gunner uses the optics and joystick to acquire the target and monitors the track. Maximum target lock-on range is 7000 m, and accuracy is 1.5 mrad and 30 ft in range. Maximum radial target speed is Mach

1.8. The director's angular rate in both axes is 2 rad/sec. Elevation limits: +90/-25 deg.

Total weight of Mk 1 is 1323 lb; of Mk 3 Mod 0, 1778 lb; of Mk 3 Mod 1, 350.7 lb.

AIRBORNE RADARS AND FIRE-CONTROL SYSTEMS

FRANCE

◆ Vigil

Vigil is Thomson-CSF's project for an X-band early-warning radar for the next generation of French aircraft carriers. It is to enter service in 1992. It uses the programmable signal processor and waveform developed for the existing RDY fighter radar, plus an electronically scanned antenna. Total weight, exclusive of consoles, will be 450 kg. The radar will be installed on board refurbished Grumman Tracker aircraft (originally built for carrier-based ASW) in a belly radome; the aircraft will be re-engined with turboprops. There will be 2 operators, the radar automatically detecting and tracking targets and automatically computing intercepts. Thomson-CSF, the manufacturer, estimates that Vigil will detect a 5-m² target at 110 nm, based on performance already achieved by RDY (using a smaller antenna).

RDY itself is a multifunction (air-to-air, air-to-ground, and air-to-sea) radar, achieving this capability by means of a programmable signal processor (as in the U.S. APG-65). For air-to-air operation, it can use 1 of 3 waveforms (high, medium, and low PRF). It can track 8 targets while scanning, each target being assigned a priority label. Simultaneous fire-control solutions can be computed for several targets, so that a fighter equipped with RDY can engage several simultaneously using active missiles. Alternatively, the radar can be used to illuminate a target for a semiactive missile. The air-to-ground modes of operation are ground mapping (RBGM) and doppler beam sharpening (DBS) for navigation; and air-to-ground ranging (AGR) and detection and tracking of fixed (HTT) and moving (GMTI/GMTT) targets. The radar is also designed for sea search, using a variety of waveforms to cancel clutter at different sea-states.

RDY is a pulse-compression radar (with a variable compression ratio), using 2 different peak-power levels (dual-mode operation). The transmitter uses a TWT.

The radars of current French maritime-patrol aircraft all have some air-to-air capability to provide surface ships with limited support.

USSR

The new Soviet aircraft carriers *Tblisi* and *Riga* will be equipped with MiG-29 (Fulcrum) and Su-27 (Flanker) fighters, both of which have air-to-air radars. It is not clear whether the Yak-41, the follow-on to the current Yak-38 (Forger), will have any more radar than its predecessor, but in the past the Soviets have tended to assign odd numbers to fighters and even numbers to bombers.

◆ Slot Back (RP-29)

Slot Back is the doppler look-down/shoot-down radar of the Su-27 and the MiG-29; it is not definite, however, that both aircraft carry exactly the same version. Reportedly, Slot Back incorporates APG-65 technology (1 report suggests that it is a copied APG-65, a wag suggesting that some of the assemblies can be replaced part-by-part by APG-65 parts). Reports of capabilities vary; at the Farnborough air show in 1990 a Soviet designer claimed a range of 80 km [43.7 nm], which is short of earlier estimates (100 km [about 54 nm]). RP-29 is the Soviet service designation (NO-193 is the maintenance designation).

A report of 130-nm search range and 100-nm tracking range, sometimes claimed for Slot Back, more likely refers to Flash Dance, the MiG-31 strategic interceptor radar.

UNITED STATES

◆ APG-65/APG-73

The Hornet (F/A-18) dual-purpose fire-control radar (air-to-air and air-to-surface) was developed by Hughes. It is now in service in the U.S. Navy and also in Canada, Australia, and Spain. This radar has also been adopted by West Germany for the F-4F improved-combat-efficiency (ICE) upgrade program.

The most important new feature is a high-speed (7.2-MFLOP) software-programmable signal processor (PSP), which makes the radar flexible. Doppler-filter and range-gate configurations are defined by software, whereas in previous fighter radars these configurations were hard-wired.

The antenna is a low-sidelobe planar array with direct electric drive rather than the hydraulic drive of earlier airborne radars.

Air-to-air modes are velocity-search, range-while-scan, TWS, single-target-track, raid-assessment (expanded coverage of a target to resolve a raid into individual aircraft), air-combat-maneuvering, and gun-director. There are also a narrow-beam vertical-scan mode and a bore-sight-acquisition mode in which the pilot points the airplane at a target. In the acquisition mode, the radar searches the entire volume equivalent to the heads-up display (HUD) and locks onto the first target detected. The gun-director mode uses pulse-to-pulse frequency agility to reduce target scintillation, for highly precise tracking. As in AWG-9, the longest range is achieved in velocity search (high PRF giving only velocity and bearing data). The range-while-scan mode uses a combination of interleaved high and medium PRF waveforms, the high-PRF waveform giving some range data and the medium-PRF waveform permitting the use of range-gate processing. TWS gives the shortest ranges. Single-target-tracking uses monopulse angle logic and can extrapolate the target's position while the target fades out of view during violent maneuvers; this mode employs a special high-PRF waveform for Sparrow guidance.

Air-to-surface modes are real-beam-ground-mapping, doppler-beam-sharpening (sector or patch), synthetic-aperture, fixed-target-track, sea-surface-track, terrain-avoidance, precision-velocity-update, and air-to-surface-ranging. Doppler-beam-sharpening achieves a 19:1 improvement in sector scan and a 67:1 improvement in patch mode.

The claimed MTBF is more than 100 hr. The entire system weighs 340 lb (exclusive of rack) and occupies less than 4.5 ft³. In comparison, the APG-63 of the F-15 weighs 483 lb and occupies just less than 9 ft³, exclusive of the antenna. Digital operation greatly reduces field adjustments; Hughes claims that built-in test equipment can detect 98% of all faults.

APG-65 prototype, showing the microwave plumbing behind the flat slotted-array antenna. (Hughes)

GROUND TRUTH

DOPPLER BEAM SHARPENING PATCH (short range)

DOPPLER BEAM SHARPENING SECTOR

DOPPLER BEAM SHARPENING PATCH (long range)

Effect of Doppler beam sharpening in an APG-65 ground-mapping display. (Hughes)

The current APG-65 upgrade (the operational requirement was promulgated on 27 January 1988) exploits APG-70 and -71 development work and uses parts of those radars. Hardware design is to begin during FY90, rooftop integration of hardware and software following in FY91, with flight tests in FY92.

In early 1989 the marines chose APG-65 as their preferred Harrier (AV-8B upgrade) radar, despite some legal obstacles (the radar project was not subject to formal competition, although the marines did fly several alternative radars first). The new radar is part of a more general Harrier II Plus program. As of August 1990, the projected FY91 program called for 20-27 new Harrier II Plus, and the marines hope to upgrade 193 existing AV-8Bs, beginning with 12 each in FY92 and FY93, then 24 per

year from 1994 on; the Harrier II Plus is to enter service in 1993. Spain plans a similar upgrade (and will buy 6 new Harrier II Plus), and Italy is to buy Harrier II Plus for the carrier *Giusseppe Garibaldi*. Reportedly, Japan is considering buying Harrier II Plus for the JMSDF.

The radar must be modified to fit the Harrier; like the Blue Vixen in a Sea Harrier, it has to be spread out through the fuselage (the signal processor and data processor are moved to the rear fuselage). The antenna is reduced in diameter to about 22.8 in.

APG-73 is a modernized F/A-18 radar by Hughes Radar Systems. Work began in 1989, and the first development radar is to be completed in mid-1991; Hughes hopes for a production contract in October 1991, with first deliveries in 1994. APG-73 should appear in time to be installed on 600 new F/A-18s, and it may be used to retrofit night-attack F/A-18s, providing them with greater computer capacity. APG-73 retains the transmitter

and antenna of the APG-65 but replaces the signal-processor, data processor, and receiver/exciter of the earlier radar.

APG-65 is being installed on German land-based F-4F Phantom fighters as part of an upgrade program. An evolved version was proposed, but not chosen, for the projected European Fighter Aircraft.

◆ APG-71

This replacement for the AWG-9 in the F-14D upgraded Tomcat incorporates some APG-70 (F-15C/D/E) technology but retains features of the original AWG-9. The first production unit is scheduled for delivery in September 1989. The signal processors of the APG-70 and -71 are 86% common.

APG-71 began as a digital version of AWG-9; Grumman and Hughes tried to introduce a digital signal processor into AWG-9 Block V; the proposal went as far as the technical-evaluation stage, but it was never completed. When it was finally adopted, the change in designation from AWG-series to APG-71 reflected a fundamental change: Hughes became a subcontractor to Grumman, the builder and aircraft-system integrator, rather than the prime contractor of a separate system.

Most analog radar functions are replaced by digital equivalents, and this digital operation made it possible to introduce a programmable signal processor (for multimode operation), by means of which the system as a whole could be modified by software. In addition, the antenna was now digitally controlled and, therefore, could be scanned in a pattern chosen by the radar computer. Operating in TWS mode (which requires target illumination every 2 sec), the antenna can be commanded to "steal" an occasional scan to look at other targets of interest. Because the radar signals are carried in digital form, the computer can analyze them in greater detail, for noncooperative target identification.

Because the existing AWG-9 is still the most powerful airborne fighter radar, APG-71 retains its transmitter and power supply. However, it has a new broad-band master radar oscillator. There is also a new receiver, with better Doppler resolution, for better track accuracy and discrimination between nearby targets. The receiver employs a new high-speed analog-to-digital converter to achieve a combination of spectral purity and dynamic range. There is also a new digital raster-scan display, which can show infrared video as well as raw and processed radar video.

Thanks to the digital processor, the new radar has better overland performance and can operate in ground-mapping and ground-attack modes. Overland performance will be improved further by a future medium-PRF mode. The radar should also enjoy broader velocity search coverage (eliminating the need for separate settings depending on whether the target is approaching or retiring), a more flexible target-engagement zone, a new long-range passive-identification mode (to count closely bunched aircraft), and programmable ECCM and clutter control.

One consequence of the new antenna control is that the radar is no longer constrained to fixed 2- and 4-bar patterns, which in the past had prevented it from detecting some targets that were widely separated vertically. In bar scanning, the radar sweeps across a bar before shifting to the next bar below. In the new mode, the scan can be interrupted to track a target (even if it is outside the normal pattern), then return to scanning.

Presumably APG-71 incorporates the new radar waveform projected for the APG-70: range-gated high PRF. In the past, the choice has always been between low PRF for long-range and high PRF for good doppler performance but short unambiguous range. Moreover, high PRF is best for an airplane approaching at high speed, whereas medium PRF is best for a tail chase. Typical fighter radars interleave the 2 PRFs in a "4 bar" search, leaving some gaps in coverage. APG-70 uses a combination of range gates and doppler filters (20,000 filters, 500 per range gate); the PRF is 200,000. The new technique should also make raid assessment much more accurate.

The new signal processor has 4 units compared to 3 in the

F-15 and operates at 40 MCOPS. The associated digital data processor operates at 3.2 MIPS.

APG-71 flight tests, on board a converted TA-3B, began in July 1987.

◆ APQ-104

Band: X **Beam:** 4.5 deg **Peak Power:** 160 kW **Gain:** 31 dB
Pulse Width: 0.7 microsec **PRF:** 1200 pps
Scan Rate: 71 deg/sec horizontal, 30 scans/min vertical
Antenna Dimensions: diameter 20 in
Antenna Weight: total weight 537 lb

The radar for the U.S.-built French F-8E(FN) replaces the APQ-94 of earlier U.S. versions of this airplane, for compatibility with the French R.550 missile. APQ-94 was presumably similar; its characteristics are listed above. APQ-94 used a magnetron transmitter and hence was not a pulse-doppler radar. Presumably the modification represented by APQ-104 was a CW injection mode.

APQ-94 was built by Magnavox.

◆ APS-120/125/138/139/145

Band: UHF (400–450 MHz) **Beam:** 7 × 20 deg
Peak Power: 1 MW **Gain:** 21.5 dB
Pulse Width: 13 microsec (compressed to 0.2 microsec)
PRF: 300 pps **Scan Rate:** 6 rpm
Antenna Dimensions: 2.5 × 24 ft (in rotodome)
Antenna Weight: 1700 lb

Data are for APS-96, the predecessor to the current APS-120/125/138/139, to give some idea of overall characteristics. APS-96 is no longer in service. These characteristics are quite comparable to those of the UHF shipboard radar, SPS-40.

The standard U.S. naval airborne early-warning radar, installed on the Grumman E-2C Hawkeye, the General Electric APS-125 is now also in service in Egypt, Israel, and Japan. Lockheed is marketing an alternative installation on board converted P-3 airframes for land-based naval air surveillance, perhaps by Australia and Norway; this look-down P-3 is now entering service with the U.S. Customs Service. Although APS-125 and

The Grumman Hawkeye carries an air-search radar comparable in size to that found on board a major surface ship. (Grumman)

Since 1986, Grumman has been testing a conformal (active phased-array) radar to replace the rotodome of the current E-2C. Arrays occupy leading edges of the wings, and others could be installed in the leading edge of the tail. The test rig, which includes a rotodome, is shown. Grumman expects to have a flying system by 1992 or 1993, for service introduction in the late 1990s. The array has to adapt its beam form as the wing flexes, and Grumman achieves this adaptation by means of rapid feed-back calculations at each of the thousands of antenna elements. The system has been tested by running a propeller just ahead of the wing. The company points out that, quite apart from the advantage of reducing airframe drag, a conformal array is not limited to a steady scanning rate. Instead, the array can concentrate on areas of particular interest. Such operation might help separate a stealthy target from its background; reportedly the ability to dwell on areas of interest may, by itself, add 20–30% to the effective detection range. Reportedly, too, the new conformal array uses instantaneous radial-velocity measurement (presumably by FFT applied to returning echoes) to separate targets of interest from sea clutter. (Grumman)

its relatives are primarily intended for air search, they have a very significant surface search capability, and aircraft equipped with these radars can control antiship attacks. The functional predecessor radar, APS-20, is now used exclusively for surface search. (See the Strike/Surface Warfare section for details.)

UHF frequency was chosen for maximum ability to detect small targets at long range (based partly on available transmitter power) and for sea-clutter rejection (transmitter stability, pulse compression for high resolution, and single-delay analog AMTI). The selection of UHF paralleled the shift to such UHF shipboard radars as SPS-17 (which led to SPS-37/43). The first such U.S. AEW radar, APS-70 (425 MHz, 2 MW), was designed for airship use, and in tests it achieved 40% greater range than comparable earlier S-band sets. The E-2 radars were conceived about 1957 as the carrier-based equivalents of the big airship radar. The earlier AEW radars (APS-20 and -82) operated at S-band and, although they had considerable transmitted power (e.g., 1 MW in APS-82), they also suffered greater transmission losses. Thus APS-96 was credited with somewhat greater range than APS-82 at the same transmitted power. Maximum range, as limited by PRF, was over 200 nm, about twice the nominal range of APS-82.

The current (APS-138, or TRAC-A) antenna is an array of 2 rows each of 8 yagis (1 row of 12 in earlier versions) in a rotodome (a rotating radome) 24 ft in diameter and 2.5 ft deep rotating at 6 rpm. It uses monopulse processing to achieve narrow beam definition in the horizontal plane, dividing the antenna in half and comparing sum and difference signals, which are separately pulse-compressed. There are also 2 auxiliary antennas used for sidelobe cancellation. Previous versions of the radar used an array of 12 yagis in the rotodome. The radar measures target altitude by comparing pulses reflected directly by the target to pulses that have reflected off the surface as well as the target (either coming or going or both). This technique is probably effective mainly at sea, where the surface is highly reflective. In contrast, it appears that the APY-1 radar of the Boeing E-3 AWACS produces a beam narrow in both azimuth and ele-

vation, sweeping the beam vertically for height-finding. That scheme reflects that radar's primary function, which is air search over land.

APS-96 did not incorporate the AMTI initially specified (primarily to detect small low fliers at long range). The method employed, comparison of echoes on a pulse-to-pulse basis (the differences being detected as beat frequencies in filter banks), required very stable transmitter frequency. Existing klystrons were too massive for airborne use, so a special tetrode amplifier tube was developed. APS-111 (1963) introduced AMTI into this radar series. This AMTI was ineffective in eliminating land clutter, and further measures were necessary. AMTI processing is now digital, and the radar is sometimes described as pseudo-pulse Doppler.

APS-125 is a modified successor to APS-96, the original E-2 radar, via the APS-111 of the E-2B and the APS-120 of early E-2Cs. APS-111 had improved clutter rejection for overland operation, including special circuits to cancel out the clutter that was frequency shifted by aircraft operation and that would have interfered with both moving target indication and pulse compression. There were also new techniques for sidelobe suppression. APS-111 was tested in 1964–68, and APS-120 incorporated these improvements plus an automatic radar detector, linking the radar to the tracking-and-intercept computer (airborne ADT). The computer seeks a constant false-alarm rate (CFAR) and sorts radar returns before presenting them to the intercept operators. APS-120 also had a more stable (and more reliable) radar transmitter.

APS-125 uses 2 MTI techniques in succession, cancellation and pseudo-doppler. Both use the doppler shift imparted to a signal returned from a moving target, but in different ways. For cancellation, the effect of the doppler shift is approximated by a change in the overall phase of the returning signal. That signal can be compared to a reference signal, to eliminate (cancel) non-moving targets (clutter), i.e., targets showing no phase shift. This form of MTI is mathematically equivalent to analyzing a signal for doppler shifts. Like any pulse-doppler radar, an MTI radar has a series of blind speeds proportional to its PRF (when the phase shift reaches 360 deg, it is equivalent to zero). Any real system, moreover, finds it difficult to detect phase shifts near the blind speeds; these areas of small response are called notches. One of the blind speeds is at zero relative velocity, and the object of the phase comparison (cancellation) is to leave as much of the clutter as possible in the notch around zero. APS-125 uses a triple canceler.

In the case of a moving airborne radar (like APS-125), the clutter has an average velocity centered around the speed of the airplane. The MTI canceler can shift the notches so that the center speed of the clutter lies in a notch. TACCAR (time-averaged-clutter coherent airborne radar) automatically centers the notch at the average doppler frequency of the clutter. Clutter is worst at short ranges, the altitude of the airplane determining the point at which detection markedly improves. This point is at a range of about 170 nm for an E-2C at 23,000 ft over land.

After pulse compression, APS-125 converts its signals into 10-bit digital words (60-dB dynamic range), the word rate out of the converter being 5 MHz. They are passed through a 3-pulse canceler that eliminates the bulk of the clutter (the very stable radar transmitter is said to make for a 55-dB improvement in signal-to-clutter ratio at this stage).

Then comes pseudo-doppler processing. The digital signals are passed through a 16-point FFT. Each FFT output (i.e., each velocity signal) is individually threshold-detected, and these signals are subject to processing (beam splitting, velocity ambiguity removal, selectable low-speed target censoring, blanking).

This form of doppler processing is very different from that in typical pulse-doppler radars. The frequency range in the chirped pulses has already been eliminated by pulse compression. Because the radar's PRF is very low (to achieve long unambiguous range), the first blind speed is also very low, and velocity (obtained by using the FFT) is ambiguous. A nominal PRF of 300

pps corresponds to a first blind speed of 200 kt. However, because the antenna rotates slowly, a target will be painted many times while it is in the main beam (dwell period), and the radar can estimate its velocity by noting the change of range during each dwell. This estimate is then used to remove the ambiguity in the output of the FFT (velocity is ambiguous because the PRF is limited, to obtain unambiguous ranges). This processing is possible because the radar transmitter is extremely stable on a pulse-to-pulse basis.

Given doppler processing, the system defines a series of optimum velocities centered between the pairs of notches. As the target velocity falls farther and farther below optimum, the signal involved falls into the notches. In the case of APS-125, the nominal PRF, 300 pps, corresponds to 200 kt between blind speeds. The flat part of the response curve extends about 65 kt above or below the optimum velocity, and detection becomes marginal when the target velocity is within about 25 kt of a blind speed. Presumably, this problem is solved by periodically shifting the PRF, hence shifting the blind speeds and the corresponding notches.

The APS-125 digital (rather than the previous analog) processor is called ARPS (Advanced Radar-Processing Subsystem). It provides better clutter rejection and false-alarm control, for fully automatic overland operation. It also has lower sidelobes (to suppress sidelobe jamming). ARPS tests began in December 1972, and an APS-120 retrofit program began in 1977. APS-125 is said to be able to track 300 targets simultaneously, out to a maximum range of 250 nm. This capability is the ATD modification to the basic radar. After tests, the operational-test-and-evaluation force recommended that the system be modified to alert the operator if performance was degraded for any reason. Such degradation (e.g., through jamming) must be a major worry in automatic detection systems. It was also suggested that some rapid means be provided to clear the detector processor of alerts without shutting it down (i.e., as a means of clearing saturation that results from false targets).

The next improvement was APS-138, which has a new low-sidelobe antenna (total radiation aperture control antenna, TRAC-A). The first was delivered to Grumman in December 1982. All 84 existing APS-125s are being brought up to -138 standards. APS-138 can reportedly track a cruise missile at a range of 150 nm. Goodyear (Loral) claimed that, equipped with an array processor, an E-2C equipped with TRAC-A can track over 600 targets simultaneously, and can direct more than 40 simultaneous interceptions. However, TRAC-A was initially unsuccessful, the operational-test-and-evaluation force calling for broad-band TRAC-A in all 10 radar channels and improvement to match ARPS performance levels. The system passed an operational test in June 1983 but still suffered from excessive weight.

APS-139 is a further improvement with better ECCM and better surface-search performance. Scheduled to enter service in 1988, this radar can reportedly maintain over 2400 tracks simultaneously. It will be introduced in aircraft number 122.

APS-145 further rejects overland clutter, using environmental processing, in which radar sensitivity is adjusted cell by cell (range interval $\times$ beamwidth) on the basis of the clutter and traffic in that cell. PRF is being reduced to permit detections at ranges as great as 350 nm, and the scan rate is being reduced from 6 to 5 rpm. PRF may be varied during operation to eliminate target blind speeds. APS-145 was under test in 1988 and is scheduled to enter service in 1990. APS-125 and its successors all transmit on 10 channels. In early versions, channel selection was manual. However, in APS-145 channels are monitored and automatically selected, to avoid jamming signals; channels are selected on a scan-to-scan basis (every 12 sec). Grumman and GE tested a 100-channel version for the U.S. Navy, but that version was not deemed necessary. Automatic channel selection was important for the 1986 GE bid for the British AEW (Nimrod 2) contract; APS-125 was initially rejected because it would have interfered with some other NATO signals. GE argued that the new automatic selection system would avoid such

interference. Similar problems had already been overcome in Japan (where there was fear of interference with the taxi-radio band).

These radars initially fed their data into a magnetic-drum computer, which was replaced by a Litton L-304 digital computer in the late 1960s; and in 1972 the Litton OL-77/ASQ was introduced. It was initially built around 2 L-304s with eight 8k memory units. As of 1982, about 50% more capacity had been added.

The new airship is initially to carry a modified APS-138 or -139 with a 40×10 -ft antenna, for operational testing. However, advocates of the airship for fleet air defense have proposed a longer-wavelength (for antistealth operation) antenna wrapped around the airship envelope.

All of these radars are manufactured by General Electric.

For some years Grumman and General Electric have been working on a next-generation conformal-array AEW radar. A passive receiver in a wing structure passed ground tests during the summer of 1984.

See also ATDS, the airborne tactical data system fed by the E-2C's radar (described with NTDS in the Surveillance and Control section).

◆ AWG-9

Band: X **Beam:** 2.3 deg

Peak Power: 10 kW (average: up to 7 kW in pulse-doppler mode, up to 500 W in pulse mode)

Pulse Width: 0.4 and 50 microsec (pulse) 0.4, 1.3, 2.0, 2.7 microsec (pulse doppler)

Scan Rate: horizontal: 80 deg/sec
vertical: 2 scans/sec

Antenna Dimensions: 36 in (gain 37.5 dB)

Data above date to the early 1970s, and current AWG-9 characteristics have probably been modified.

The F-14 Tomcat's radar is built by Hughes. It weighs about 1300 lb, and volume is about 28 ft³. The antenna is a 36-in slotted-plate planar array, with 12 (6×2) IFF dipoles on its face. AWG-9 uses a variety of raster-scan patterns, designated by their horizontal sweep width and by their vertical extent in "bars"; they range from 8 bars and 65 deg (to either side of the airplane every 13 sec) down to 1 bar and 10 deg every quarter-second. Other azimuth limits are 20 and 40 deg; search in elevation can cover 1, 2, 4, or 8 bars. There is also a vertical-scan lock-on (VLS) mode in which the radar sweeps a 4.8-deg-wide beam up and down over a 40-deg vertical sector, which can extend from -15 to +25 deg, up to +15 to +55 deg.

There are 6 pulse-doppler modes: pulse-doppler search (PDS, giving only range rate and bearing: 5-m² target detected at 115 nm); range-while-search (RWS, to 90 nm, giving range, range rate, and bearing); TWS (to 90 nm, forming a complete track file, and limited to 2 bars/40 deg or 4 bars/20 deg to achieve sufficient data rate); pulse-doppler single-target-track (PDSTT, including both velocity tracking and jam-angle tracking, JAT). There is also an associated slaved mode for use with an IR tracker, permitting illumination of a selected IR target. Pure pulse modes are pulse search (PS, out to 63 nm) and pulse single-target-track (PSTT, out to 49 nm). There is also a slaved pulse mode. Finally, there are 3 mixed modes: pilot-rapid-location (PRL, a lock-on using a 2.3-deg beam centered on the pilot's line of sight), vertical-scan lock-on, and manual rapid lock-on. Each is effective out to 5 nm, presumably using the spacing of the doppler pulses. The TWS mode is used only for Phoenix missile launch, the radar achieving a 2-sec data rate.

The radar intercept officer (RIO) in the F-14 back seat has 2 displays, a 5-in multimode display of raw radar video, plus a 10-in processed data display using NTDS symbology, and including target tracks.

Reportedly, AWG-9 achieves 2.5 times the range of the AWG-10 installed at about the same time in F-4J Phantoms. AWG-9 can track 24 targets simultaneously. A measure of its radiated power is its ability to guide an AIM-7F Sparrow at a range of 38 nm, compared to 24 nm for earlier radars.

AWG-9 is being replaced by APG-71 in the F-14D upgraded Tomcat.

In the new F-14D, AWG-9 is replaced by a digital version, APG-71 (see the separate entry).

◆ AAAWES

Advanced Airborne Anti-air Warfare Weapons-Engagement System, a project for airborne cooperative engagements, is similar in concept to BGAAWC. AAAWES is a 2-yr (1989-91) exploratory program at Point Mugu. A sufficiently broad-band digital link should enable several aircraft to share a common tactical picture. One airplane could control missiles fired by another; it could also operate in radar silence, using another's radar picture. Some forms of jamming could be overcome because they are so directional. Current data links (Link 4A and Link 11) cannot carry sufficient information for the deployed fighters to share the tactical picture in enough detail. Ultimately, the fighters will share multisensor data. The full program will probably take at least 10 yr to field. Hughes Radar Systems Group won the test/demonstration contract in July 1989. At this stage perhaps the most important program issue is the development of sufficiently capacious LPI communications, presumably achieved in part by using highly directional antennas.

◆ IRSTS

General Electric's infrared search and tracking device is for use in the F-14D fighter. The production decision was to be made in the fall of 1989. IRSTS is conceived as complementary to the AWG-9 or APG-71 radar, allowing the F-14 to passively detect and track aircraft at long range. IRSTS flight tests began on board an air force F-15 in the summer of 1988 and continued on a modified F-14A.

Compared to a search radar, an IRSTS has a wider field of view and a narrower effective beamwidth, although IRSTS cannot determine a target's range. The narrow beam makes it possible to distinguish aircraft within a distant raid, and current systems can track multiple targets simultaneously, on a TWS basis. In theory, an IRSTS could be used to set up a missile fire-control solution, the firing aircraft using its radar (or a laser range-finder) only for a 1-time check on the target's range. Such practice would be analogous to the submariners' technique of passive tracking plus single-ping ranging and would greatly reduce the warning provided by an enemy's radar receiver. On the other hand, infrared radiation does not pass through clouds and other weather, so a pure infrared sensor system is unlikely to be satisfactory.

The current IRSTS operates in the mid-infrared (3-5-micron band) and uses a linear focal plane array of 256 indium-antimonide detectors. The focusing IR optics scan this array, in effect, over the scene outside the fighter to form an image. Compared to staring FLIRs, this system scans a very narrow beam over its array, providing greater range. Software is used to reject

clutter and such hot spots as solar reflections off clouds. Future detectors may use 4×256 or 8×256 arrays. Both General Electric and Martin Marietta have also experimented with longer-wave (8-12-micron band) mercury-cadmium-telluride arrays; 1 is to fly on board an F-14A at Point Mugu in May 1989. The longer-wave system is expected to provide longer range, as well as better performance against targets with reduced IR signatures, such as slow aircraft and cruise missiles. As of early 1989, it will probably be the one chosen for production.

As currently designed, the IRSTS gimbaled infrared optics weigh 85 lb and have a diameter of 9 in. The system consists of 2 weapon replaceable assemblies (WRAs), the sensor head and the processor.

IRSTS appears as navy fighters move from the current analog cockpit arrangement to a new "glass cockpit," in which all of the single-purpose dials are replaced by multipurpose digital CRTs. In such a cockpit, the pilot can use the same CRT to view radar or IRSTS (or TCS—see below) images. In theory, the CRT could also be arranged to superimpose or compare such images, to simplify the pilot's task of interpretation. Simplified interpretation has certainly been the effect of analogous developments in surface ships' systems.

The IRSTS chin pod was originally designed to be interchangeable with the television chin pod (TCS), but it has been decided that F-14Ds will all have dual pods.

Airborne infrared sensors have had a long history in U.S. fighters. In the mid- to late 1960s, many IR sensors were carried by North American Air Defense Command aircraft such as F-106s, and the F-14 originally incorporated such a sensor. These devices were abandoned because their range was very limited, because they provided very limited data, and because their false-alarm rates were high. F-14As were initially produced carrying a chin-mounted ALR-23 infrared detector, whose seeker head could slew independently of the fighter's radar. ALR-23 was not an imaging device. It operated in the 3-5-micron band and used an indium-antimonide detector cooled by a closed-cycle Stirling refrigerator. Reportedly, ALR-23 was provided largely to detect the Soviet MiG-25 Foxbat, which would have presented a very hot target image against a cold sky. The sensor proved ineffective and was soon deleted from the F-14. Many aircraft were completed without any chin pods, but the pod originally designed for the ALR-23 was used instead for a television, the TCS.

By the late 1970s a new generation of IR technology was available. A new air force IRSTS program was begun in 1981, and the U.S. Navy joined in 1984. Official justifications for IRSTS include the claim that the sensor may help to detect aircraft with low (i.e., stealthy) radar cross sections.

The new-generation IRSTS was first flight-tested in 1985, but the air force reduced its participation in the program in February 1986. Reportedly, the air force considered the sensor less effective than expected in a look-down situation. The navy, planning to use the sensor in the outer air battle (where the targets would generally be at considerable altitude, against a cool sky), remained in the program and approved full-scale development in 1986. Recent improvements in IRSTS have satisfied most air force concerns, although there are still no plans to place the sensor on F-15s.

General Electric is prime contractor; Martin Marietta was selected as second-source contractor in June 1987. As of early 1989, production was expected to begin in FY90. In January 1989 the U.S. Navy requested industry proposals for an integrated long-wave IRSTS/laser range-finder, for large aircraft such as P-3s, capable of tracking multiple targets at ranges beyond 100 km. Such a system might also be applicable to the E-2 or to a future unmanned fleet early-warning airplane.

◆ TCS (AXX-1)

Northrop's television camera sight for the F-14A incorporates a stabilized long-range telescope in a chin pod. The TCS was introduced to provide fighters with a means of positively identifying targets even at very long range, so that the planes could

IRSTS infrared sensor under the nose of an F-14A for tests. The operational version will be 1 of 2 identical under-nose pods, side by side, the other containing the television camera sight (TCS). The protrusion under the chin pod is an ALQ-100 jammer. (GE Aerospace)

use their long-range air-to-air missiles effectively. Prior to the advent of the TCS, typical rules of engagement required the fighter virtually to fly alongside its target before firing. That handicap was unacceptable when enemy aircraft carried long-range air-to-air missiles.

The optics have to be stabilized to keep the very distant object in view as the F-14A moves. TCS can be used independently, e.g., in an automatic search and target-acquisition mode (in analogy to shipboard optronics), or it can be slaved to the AWG-9 radar for target identification. The TCS image is captured by a video recorder on board the fighter. The telescope has a magnification of 10 and can scan over a 30-deg FOV. The instantaneous FOV is selectable as either narrow (0.44 deg) or wide (1.42 deg); the black-and-white image is presented on the pilot's vertical display indicator and on the radar officer's tactical information display.

The television pictures of the battle between navy F-14s and Libyan MiG-23s in January 1989 were taken by TCS. TCS production began in 1981, and as of 1988 all F-14As were equipped with this pod.

TCS is descended from the U.S. Air Force TISEO, target identification system, electro-optical (ASX-1), which was developed in the early 1970s as part of the Rivet Haste and Combat Tree programs. TISEO's camera and stabilized telescope are mounted in the left wing's leading edge on some air force F-4E fighters, with the video processor and power supply in the body of the airplane; and the video image is shared with the back-seat radar display. Over 500 TISEOs were delivered during the 1970s. They allowed a pilot to identify potential targets well beyond normal visual range and, thus, to use long-range air-to-air missiles (Sparrows) even under stringent rules of engagement, solving one of the major problems of air combat in Vietnam.

Navy tests of an adapted version, TVSU, the television sight unit, began in 1977. Typical effective range was 9 nm, compared to 2 or 3 for the unaided eye; reportedly observers could even decide what sort of stores the observed aircraft were carrying. That was certainly the case for the TCS-equipped F-14s in the 1989 Libyan incident. TVSU was tested at sea, on board the carriers *Kennedy* and *Constellation*, in the summer of 1978, proving particularly successful in reconnaissance. An airplane detecting a ship on radar could slave TVSU to the radar image and obtain a usable ship image at a range as great as 50 miles. TCS is a fully navalized version of TVSU.

SURFACE-TO-AIR MISSILES

BRAZIL

◆ Avibras SSA-N-1

Dimensions: 15 cm × 2.72 m [5.9 × 107 in]
Weight: 85 kg [187 lb] **Warhead:** 12 kg [26.4 lb]
Propulsion: Rocket **Speed:** Mach 2.0+
Range: max 6 km [6600 yd]

Data apply to the air-to-air Piranha missile (MAA-1).

SSA-N-1 is a ship-launched version of the Piranha (MAA-1) air-to-air missile, which is replacing Sidewinders in Brazilian service. SSA-N-1 is manufactured by the Centro Tecnico Aeroespacial (CTA) of Brazil. Concept studies were conducted in 1975, and development began in March 1976. However, the army and navy withdrew from the program late in 1977, returning only in mid-1982. The first trials were completed in mid-1984, and the air-to-air weapon entered service in 1987. Reportedly, there were initially some problems with motors, and at least 6 French-built motors were provided for the prototypes.

The naval version was to have armed later-production Brazilian patrol frigates, which will be built during the 1990s. Since the missile itself broadly resembles Sidewinder, presumably the surface-to-air version would have been comparable to Chaparral. However, this system was canceled in 1987 when the Brazilian military budget was cut by 20%. Given the erratic history of the program, it may be revived later.

CHINA (PRC)

◆ RF-61/SD-1

Dimensions: 28.6 cm × 3.99 m; span 1.166 m [11.3 × 157 × 45.9 in] **Weight:** 320 kg [705 lb]
Warhead: continuous-rod warhead
Propulsion: single-stage rocket (boost-glide) **Speed:** Mach 3
Range: 10 km against a low-flying target; maximum altitude is 8 km; maximum range at that altitude, about 5.5 km [10,900; 8700; 6000 yd]

HQ-61. (U.S. Naval Institute)

RF-61 is a ship-launched short-range surface-to-air missile. Guidance is semiactive, using a tracker-illuminator and a rear reference beam for proportional navigation.

The missile's configuration broadly matches that of the U.S. Sparrow, although RF-61 is a much larger weapon. It is unique among rail-launched surface-to-air missiles in lying atop, rather than being suspended from, the (twin) launching rail.

RF-61 was first exhibited in 1986 although it has not yet been offered for export. The missile is made by CPMIEC, the commercial arm of the Ministry of Space Industry. Development seems to have been protracted; only 2 ships carrying this weapon have been built, and they were completed in the early 1970s.

RF-61 is the ship-launched version of the ground-launched HQ-61; missile weight is 320 kg, rather than the 300 kg of the ground version.

In September 1990 CPMIEC distributed brochures describing a new version of this missile, designated SD-1. However, the photograph illustrating the missile had previously been printed with the earlier HQ-61 and RF-61 designations. The ground-launched version is now designated SD-1A.

CPMIEC announced a new low-altitude missile, FM-80, at Farnborough in 1990. It is probably in the Roland or Crotale class. Although the brochure did not mention any naval application, one is likely, given the dual role of HQ-61/RF-61/SD-1.

FRANCE

◆ Crotale Naval/Crotale NG

Dimensions: 15 cm × 2.89 m; span 54 cm [5.9 × 113.7 × 21.3 in]
Weight: 80 kg [176 lb] **Warhead:** 15 kg [33 lb]
Propulsion: boost-glide rocket (SNPE Lens III motor; burn time 2.3 sec) **Speed:** Mach 2.3 (800 m/sec; 2624 ft/sec)
Range: 8.5–13 km [6.5 km vs. a sea-skimmer; 700 m minimum]. Effective range is 10+ km against an airplane and 13+ km against a helicopter. Altitude: 150–12,000 ft [9300–14,200 yd; minimum 765 yd]; see below for anti-sea-skimmer modification.

Crotale is now the standard French point-defense missile system, installed on board the 2 carriers and 10 escorts (3 F67- and 7 C70-class frigates); it is also carried by the 4 French-built Saudi *Al Madinah*-class frigates. The typical installation is an 8-round launcher and 16 reloads, manually reloaded. Reload time for the entire launcher is about 5 min. There is also a

Crotale Naval launcher with colocated fire-control radar. The IR tracker is to the left of the radar dish. (Thomson-CSF)

lightweight 4-rnd launcher, tested on board a French aviso about 1986; it replaced the ship's 100-mm gun.

The system is fired from CIC. In large ships the fire-direction radar (with associated TV camera and IR telescope) is mounted on the launcher, the missile tubes being grouped to either side. In a smaller ship, the director can be off the mount, the electronics in a deckhouse underneath. The version for small ships is modular; a larger ship uses the compact version, in which the electronics are carried in a deckhouse under the launcher/director. Thomson-CSF claims that the modular launcher is about the same size and weight as a single 40-mm gun.

Compared to the land-based version, Crotale Naval has larger-diameter tubes for launching missiles, to keep the missile's fins from striking the sides of the tube when launching in rough weather, and lighter caps.

Guidance is command to line of sight, using a radar tracking the transponder on the missile. Upon firing, the missile is gathered into the radar's line of sight by an IR tracker (FOV 5 deg). Steering is by measurement of the error angle between missile and target, using a fin-mounted transponder on the missile and a Ku-band digital data link. The monopulse doppler tracking radar has a range of 20,000 m. A second IR tracker can be used to fire a missile at a second target in anticipation that the main command channel will become free when the first target is destroyed. This anticipation-firing mode makes for quicker engagement of multiple targets, even when they are not very close together.

Reaction time is 4.5 sec from reception of the target-designation signal. Because the missile is command-guided, the system can deal with only 1 target at a time. However, Thomson-CSF points out that a really fast missile with a high single-shot kill probability can destroy several targets in rapid succession (almost certainly with the important caveat that the targets are approaching as a stream attack). For example, Mach 0.9 sea-skimmers can be intercepted successively at 8500, 4500, and 1900 m. The manufacturer claims that anticipation firing increases the engagement rate, so that 5 targets can be engaged and killed in quick succession, before they pass within the minimum engagement range.

Designed to counter missiles flying at 50-m altitude or above, Crotale originally did not have an anti-sea-skimming capability. At very low angles of elevation the tracker beam can suffer from reflections off the surface of the water (image effect). The solution was an infrared tracking/guidance system (SEID, *Système d'Ecartométrie Infra-rouge Différentielle*), which can help

Crotale engage a sea-skimmer at up to 8500 m (depending on atmospheric conditions). The system using SEID is termed EDIR, *Ecartométrie Différentielle Infra-rouge*.

Fitted with SEID, Crotale is considered effective against Mach-2.0 targets at altitudes as low as 4 m. Because tracking is by IR, the missile must be fired offset from the target so that the missile's own IR signature does not blank out the target's. Typically Crotale is made to dive at the target at a 1-deg angle. Evaluation gates around the target are used to counter possible IR countermeasures, and the manufacturer claims that interception accuracy is 0.1 mrad in a 20×30 -mrad lobe. The system evaluates the quality of the different tracking sensors available to it, choosing automatically the one most suited to the engagement.

Moreover, an improved version of the radar tracker, using special filtering, can track a missile by comparing the direct- and reflected-image (off the sea surface) radar signals, out to 3000 m. This mode is important because under some weather conditions the infrared tracker would be ineffective.

Crotale is the entire system, not the missile. The current missile is the Matra R.440N, described above, but the next-generation Crotale NG uses a new missile, the LTV VT-1 (see below).

Very low level operation also required modifying the missile's proximity fuze to reject sea clutter. Thomson-CSF claims that the combination of a proximity fuze and a directed-blast warhead (into a plane perpendicular to the missile's axis) makes for very high kill probabilities: 0.82 for an airplane at a range of 10,000 m and 0.90 for an antiship missile at a range of 8500 m. These figures are probably conditional on successful target acquisition and missile guidance.

The current motor accelerates the missile to Mach 2.3 in 2.3 sec, and the missile reaches 5 km in 10 sec and 8 km in 20 sec, by which time it is subsonic; it takes another 26 sec to get to 13 km. Matra is developing a new motor, which will enable the missile to reach 15 km in 25 sec; only beyond that range will Crotale be subsonic.

This missile was originally called Murene and was designed to engage targets at ranges between 1500 and 9000 yd. Development of the basic land missile, Crotale, was largely (85%) financed by South Africa, beginning in 1964, the British government having refused a South African order for Bloodhound missiles. The first unguided round was fired in 1965 (the first guided round was fired in September 1967). Development of the naval version began in 1972, the French navy ordering 10 systems in May 1974. The first sea-based test was in November 1978, the target, a CT20 drone, being hit at 6-km range. Trials were completed in October 1979, and series production began in January 1980. On board the carriers, 2 Crotale Naval launchers replaced the original 3.9-in battery in 1986/87, the navy having expressed concern about possible sea-skimming missile attacks when the ships were deployed off the Lebanese coast.

A next-generation version, Crotale NG, is currently in production. It was derived from the modular Crotale Naval but uses a new missile, the VT-1, developed by the U.S. firm LTV. VT-1 is to arm the new *La Fayette*-class frigates; it is not entirely clear how much more of the Crotale NG system they will have. As announced, the French navy's order was the first French sale of Crotale/EDIR, which had previously been sold to the PRC and the UAE.

The Crotale NG program began in 1985 (under the name Liberty), to meet the U.S. Army FAADS-LOS-L-H requirement (the competition was won by the Oerlikon ADATS). Crotale NG has now been adopted by Finland and by the Dutch Air Force. In this form it uses a new 200 W Signaal C/X-band radar, Varibeam, which can process up to 20 targets simultaneously, maintaining 8 tracks. The associated frequency-agile, pulse-compressed, pulse-doppler tracker can detect hovering helicopters or Mach-2 aircraft. There is also an optronic tracker. Some of these sensors would presumably be used in the naval version.

The new VT-1 missile is 2.4 m long and weighs 75 kg (95 kg for a complete round); its maximum range is 11 km at an alti-

tude of 6000 m, and its maximum speed is Mach 3.6 (average speed Mach 2.3, covering 8 km in 10 sec). At 8-km range it can maneuver at 50 Gs, compared to 20 Gs for the current Crotale missile. VT-1 has a new pseudo-randomly pulse-modulated, broad-band prox fuze developed from that of Crotale Navale; it operates between 0.2 and 0.5 sec before interception. The missile has been under development by LTV since 1986, on contract from Thomson-CSF. Production began in 1989, and the first weapons are to be delivered, for Finland, in 1991. VT-1 completed test firings in France late in February 1989.

Crotale NG uses the same multisensor (radar and IR) control approach as Crotale Naval but differs from previous Crotales in that all sensor data are sent to 1 computer, which processes them and determines guidance orders after filtering interference. Thus radar and optical modes normally operate together, checking each other constantly. The trackers define a window containing target and missile as well as false targets already detected. Each target is surrounded by a measuring window, within which measurements made by different sensors are correlated. All data are sent to a 2D filter.

Crotale NG uses a new 12-rnd, 2.6-ton launcher (6 rnds on each side, compared to 4 for Crotale). The associated director (900 kg) carries a Ku-band, pulse-Doppler, frequency-agile radar, an LLLTV, and a FLIR; it should be able to detect very low flying targets beyond 18 km [19,700 yd]. The computer processes up to 20 targets and selects the 8 most threatening; it also selects the optimum modes of target tracking and missile guidance. The operator validates the choice of most threatening target and fires; Thomson claims that only 6 sec need elapse between target detection and firing.

◆ Masurca

Dimensions: 406 mm × 5408 mm; span 1277 mm; booster length 3222 mm and tail span 1500 mm. The missile penetrates 114 mm into the booster, so total length is 8516 mm. [16 × 212.9 × 50.2 in; 126.9 × 59.0 in; total length 335.2 in]

Weight: 840 kg; booster 1858 kg [1850/4095 lb]

Warhead: 120 kg [264 lb]

Propulsion: booster (burn time 4.5 sec) plus sustainer (burn time 30 sec); booster thrust about 35 tons, sustainer thrust 2300 kg [5070-lb thrust] **Speed:** 900 m/sec max [2952 ft/sec]

Range: 40,000 m; kinematic range 62,000 m [43,700/67,800 yd]

Masurca is an area-defense weapon broadly comparable to the U.S. Terrier/SM-1(ER). The configuration is similar, but the French missile is larger and heavier. There were both semiactive and beam-riding (Mk 2 Mod 2) versions; currently only the semiactive Mk 2 Mod 3 remains in service. Fire control is by a DRBC 51 tracker-illuminator. The design requirement was to intercept two 1-m² targets at altitudes of up to 18,000 m and at ranges of 25,000 m (beam-rider) or 35,000–40,000 m (semi-active).

Like Terrier or SM-1(ER), Masurca is stowed horizontally, on a revolving drum, without the long booster fins, which are fitted by hand before firing. The rate of fire is one 2-missile salvo every 30 sec. The launcher carries a total of 46 missiles (18 per drum plus 10 missiles in reserve, broken down with missile and booster separate). Total system weight: 111.5 tons for fire control, 31.5 tons for the launcher itself, 202.0 tons for the loading system, and 105.0 tons of missiles, 450 metric tons in all.

The 3 remaining systems, on board the 2 *Suffren*-class destroyers and the cruiser *Colbert*, were modernized 1983–85 to maintain the system until the end of its scheduled life in 1998–2000.

Masurca was 1 of 5 French naval missiles whose development began in the first postwar decade: 3 anti-aircraft missiles (Masurca, Maruca, and Masalca), 1 ASW missile (Malafon), and 1 antiship missile (Malaface). Each designation indicated the role and manufacturer: MA for *marine* (navy), then the manufacturer (SUR, for Supersonique RUELLE), then the mission (CA, for *contre-avion*, anti-aircraft). For Malafon, the only other survivor of the program, LA indicated Latecoere, and FON indicated underwater (FACE was *surface*). The program was drastically reduced about 1958, as finances tightened: Masurca had

Masurca on board the cruiser *Colbert*. (ECP Armées)

DRBR 51 directors for the French Masurca missile. (*Ships of the World*)

the highest priority, and Malaface was killed on the theory that the carrier's strike aircraft had made the missile unnecessary. Masalca, developed by Latecoere, was a longer-range (95-km) anti-aircraft missile intended for a cruiser, a French equivalent of the U.S. Talos. Presumably, the related cruiser project was dropped about 1960.

◆ Mistral (Sadral and Simbad Systems)

Dimensions: 90 cm × 1.81 m [3.5 × 71.3 in]

Weight: 17 kg [37.5 lb]

Warhead: 3 kg (1800 tungsten balls) [6.6 lb]

Propulsion: boost-sustain rocket (The booster burns only inside the launch tube, accelerating the missile to 40 m/sec [131 ft/sec], and the sustainer ignites 15 m away; the motor is based on that of the Super 530 air-to-air missile.) **Speed:** Mach 2.6

Range: 6 km against aircraft; 4 km against helicopters; 6 sec to 4000 m. Minimum range: 500 m [6600/4400 yd; minimum 550 yd]

The Matra Mistral is a short-range defensive missile used in several naval systems. Matra describes the weapon as the first shoulder-fired Mach-2.5 defensive missile. It uses an all-aspect infrared seeker and a laser proximity fuze, and the manufacturer claims that Mistral can attack helicopters with reduced IR signatures. Unlike many previous IR-guided missiles, Mistral employs proportional (rather than pursuit) navigation, using a gyro as a reference. One effect of such guidance is to reject flares ejected from the rear of a target.

Sadral anti-aircraft launchers (for the Mistral missile) on board the destroyer *Cassard*. (Matra)

Breda's combined Mistral missile and SCLAR chaff launcher, 1989. (Breda)

Mistral uses a 2-color IR seeker made by SAT. The warhead uses both impact and laser fuzes. On the launcher, the missile runs up its seeker and gyro in 2 sec; total reaction time is 5 sec.

Sadral (*Système d'auto-défense rapprochée anti-aérien légère*) is a close-in 6-rnd defensive system for second-line ships, using Mistral. There is also a lightweight 2-rnd launcher, Simbad (*Système intégré de Mistral bimunition pour l'auto-défense*). Simbad is a modified 20-mm pedestal mount (a configuration that in itself explains the function of this and analogous weapons) carrying a simple optical sight.

The Sadral launcher is stabilized, elevating and training. It carries a television camera and an IR camera for night firing. The missile is locked onto the target before firing, presumably to limit the amount of background visible to the seeker, thus improving the effective signal-to-noise ratio. An audio signal indicates that the missile has locked on before it is launched. A more elaborate version of the basic Sadral mount, Lama, carries 4 or 6 missiles and an optical target designator that can act as a secondary director for other shipboard weapons.

Tests of the basic Mistral missile were completed in March 1988, with firings against low-flying CT20 drones. One firing resulted in a head-on hit at 5 km.

Sadral is in service on board French anti-aircraft frigates (C70 AA type) in a version called SATCP (*surface-air, à très courte portée*), using a CSEE automatic director and a 6-missile rapid-reload mount. Mistral is also combined with a close-in defensive gun in the proposed Samos/SAGEM close-in weapons system. An air-to-air version, A/HATCP, is planned for French Air Force helicopters; Santal is used by ground forces, and the basic man-portable infantry version is SATCP.

This program began with feasibility studies in 1978, Matra being selected as prime contractor in August 1980. The naval version was announced in October 1980, and tests began early in 1985. Deliveries of Mistral began in June 1988. As of 1988, the estimated cost per missile, including the kevlar launch tube, was \$60,000–\$100,000.

Sadral 6-missile launcher for Mistral. (Matra)

Simbad 2-missile shipboard launcher for Mistral. (Matra)

Naval users are France, Brunei, Finland, and Norway. As of late 1990, a sale to a Persian Gulf navy, probably that of the UAE, was reported as imminent. Both Finland and Norway are developing their own missile mounts. The Finnish navy is to use a converted Soviet-type, 25-mm, unstabilized, hydraulically operated, locally controlled mounting (which receives only target-designation data from the ship's CDS). The 2 guns are replaced by 6 Mistral tubes arranged in an arch above the FLIR and TV camera. Total weight is about 1500 kg. These weapons are to arm Finnish fast attack craft and minelayers. Norway ordered several hundred Mistrals in September 1990 to arm the *Storm-* and *Snogg-*class fast attack boats, with options for more for the *Hauk* class and the new mine-countermeasures craft. The attack boats will probably be armed within the 6-tube Sadral mounting, the minecraft with the 2-tube Simbad. Mistral may also be the missile chosen for the new Norwegian system described below.

◆ SAAM/ASTER

Dimensions: 18 cm × 2.6 m [7.1 × 102.4 in]; booster 36 cm × 1.6 m [14 × 63.0 in]

Weight: 100 kg [220 lb]; booster 200 kg [440 lb]

Warhead: 10–15 kg focused fragment [22–33 lb]

Propulsion: rocket

Range: 5–15 km (see below)

Data are for ASTER 15. The seeker is the AD4A used in the Matra MICA air-to-air missile. The standard 8-rnd launcher module weighs 12.5 t.

This French advanced point-defense (antimissile) missile is under development by Thomson-CSF and Aerospatiale and is the weapon of the FAMS system. The overall system is called SAAM (*Système de défense surface-air antimissile*), and the missile is ASTER. The potential targets are Mach-2.5 (15-Gs) sea-skimmers, diving antiradar missiles, and fighter aircraft. Claimed performance is a range of about 10 km against supersonic and maneuvering missiles, or 15–17 km against high-altitude aircraft and subsonic missiles. The same upper-stage missile is to be developed for land service as SAMP (*Sol-Air Moyenne Portée*). The land-based SA-90 (ASTER 30) is to be ramjet-powered; the sea-based SAN-90 (ASTER 15), rocket-powered. Otherwise, these versions have most systems in com-

ASTER with its booster. (Author)

mon, requiring radar acquisition ranges of, respectively, 25 and 10 km [27,300 and 10,900 yd].

Key design requirements are very short reaction time, multiple engagement capability, great agility, and a very short guidance time constant. Quick reaction is ensured by a combination of vertical launching (from the canister tube in which the weapon is shipped) and highly automated operation. As in the U.S. Aegis system, a flat-face phased-array radar (in this case a single rotating face), the Thomson-CSF Arabel, tracks both missile and target. The missile is sent into a terminal "basket" by a command up-link programming the autopilot. The system is designed to handle 10 targets simultaneously. Unlike the U.S. Standard Missile, however, ASTER will use active terminal guidance, requiring no dedicated illuminators. Presumably ASTER has that capability because the missile is intended to engage its targets at short range: there would not be enough time to share a few illuminators.

The designers expect that violent missile maneuverability (up to 50 Gs) will allow the weapon to approach within 2 m of its target. At that range the missile can achieve catastrophic structural damage even with a relatively light warhead. A light warhead in turn makes it possible to package high maneuverability within a reasonable volume.

The missile itself consists of a separate booster and a guided vehicle incorporating a sustainer motor. By separating booster and sustainer, the designers again reduce terminal homing weight. They achieve maneuverability by a combination of aerodynamic forces and direct-force control (i.e., rockets firing perpendicular to the axis of the missile), a system they call PIF-PAF. Direct-force control has previously been used only in antiballistic-missile weapons. For ASTER, the claimed virtues of direct-force control are that it can operate even at very high altitude and, at any altitude, can permit violent maneuvers even at low angles of attack.

As in the U.S. SM-2 Aegis (ER), the booster employs thrust-vector control to tip the missile into the appropriate trajectory.

The ASTER missile in flight. (Aérospatiale)

ASTER, however, is finned. The booster's size controls the missile's range. The naval version of the system is designated ASTER 15 (15 km); the land version, with a larger booster, is ASTER 30. At the end of acceleration, ASTER 15 should have a velocity of 1000 m/sec; ASTER 30 will be somewhat faster. The naval version will be fired from a vertical launcher employing 8-weapon cells.

Reportedly, the French credit current systems with a reaction time of 15–20 sec; using the Arabel radar, ASTER is to have a 5-sec reaction time.

The RFP for a collaborative European missile (the French government is seeking partners for SAAM/SAMP development) was issued in 1980/81, with a 31 December 1981 deadline; the Aérospatiale-Thomson-CSF development contract was announced in August 1983. The SAN-90 design was frozen in 1984 (and a model displayed at Le Bourget in October 1985). ASTER was selected over the Matra SAMAT (which is, however, being continued as a backup) early in 1986.

As of 1988, ASTER was due to enter French navy service by 1996, on board the new carrier *Charles de Gaulle*, and SAMP was due to enter French army service in 1998. The first missile test, which demonstrated PIF-PAF maneuvering, was at the French CEL test range, 17 June 1987. About 1987 the estimated unit price of an ASTER was \$400,000–\$700,000.

The overall ASTER weapons system is designated Syrinx (Système Rapide Interarmées à base d'Engins et Fonctionnant en Bande X). See also FAMS, below.

INDIA

◆ Trishul

Trishul is a quick-reaction low-level missile, developed under the Integrated Guided-Missile Development Program approved in July 1983. It is a triservice weapon, intended to be effective against sea-skimmers. As of mid-1989, it had made 8 successful flights. Production weapons were to be delivered in 1990. Trishul uses a dual-thrust rocket motor and has a range of 9 km. It employs a combination of command guidance and some form of terminal homing. A modified surveillance radar is used to intercept one target at a time, and a modified Signaal Flycatcher provides guidance. Flycatcher is an mm-wave TWS radar, made under license by Bharat Electronics.

The 1983 program also included, in its first stage, the Prithvi SSM (250 km). The missiles of the second stage, to be operational by 1993, are the medium-range Akash SAM and the Nag third-generation antitank missile.

Akash is a ramjet missile, probably similar to the Soviet land-based SA-6, which has a blended rocket-ramjet power plant. It is to be guided by a phased-array radar, which permits simultaneous engagement of several targets. A photograph of a model shows 3 missiles on a tracked launcher, similar to that used for SA-6. Presumably, Akash, like Trishul, is a triservice project, so there will probably be a naval version.

INTERNATIONAL

◆ FAMS

FAMS stands for Family of Antiair Missiles; FAMS was developed in parallel with, and as an alternative to, NAAWS. The current production partners are France, Italy, and the United Kingdom, and the missile is the French ASTER described above. Each system employs 2 radars, a long-range unit for area air search and a shorter-range tracker. Late in 1989 the French Astral was chosen as the FAMS long-range radar. There are 2 versions of the basic naval system, the short-range SAAM chosen by the French navy and the medium-range SAMP/N chosen by Italy (using the ASTER 30 missile to engage aircraft at 30 km and missiles at 12 km). Neither quite corresponds to the British LAMS requirement, which falls between them. The French variant of the system uses Arabel as its shorter-range radar; the Italian variant uses EMPAR. No British radar has been chosen, but Marconi is the lead British contractor and is a partner in EMPAR.

All FAMS systems will use Selenia's MARA computers and MAGICS consoles (each of which accommodates up to 2 MARA computers) linked by the Italian MHIDAS bus (10 Mbit/sec). MARA currently uses an 80286 processor, and in 1990 Selenia was reported to be experiencing some difficulties with the modular software it was writing. It expected these problems to be solved with the introduction of 80386 processors. Other internal MARA boards are MON (0.5 Mbytes of RAM), ERB (768 kbytes), EPROM (64 kbytes), BSU1 (bubble memory, 0.5 Mbytes), and ECM memory extension (2 Mbytes of RAM).

A FAMS consortium, Eurosam, has been formed by Aérospatiale, T-CSF, and Selenia. In October 1988 the French and Italian defense ministers agreed that their nations would collaborate on FAMS. In December 1989 the British officially chose FAMS as their next-generation naval air-defense system.

There are still some difficulties. The British wanted a local-area missile system, sufficient for limited area defense. Reportedly, they consider FAMS/ASTER much more a point, or single-ship, defensive system. In mid-1990 the British were reportedly confronting much higher costs and a much longer schedule than they had originally wanted, and there were reports that Britain was considering rejoining NAAWS. More probably, the British government hoped to improve the terms of British participation in FAMS, including the extent of industrial participation. Again, it was reported in mid-1990 that both the British and the Spanish governments were dissatisfied that the architecture of the system had already been determined, to the extent that neither country could expect much in the way of high-technology participation.

◆ NATO AAW Missile System

The NATO AAW Missile System is a U.S.-led project to replace the existing Sea Sparrow and to arm the NATO frigate. The primary requirements are quick reaction and multitarget handling, to deal with salvos of very fast low-altitude weapons like SS-N-22. The system must also be able to counter steep divers. In theory, that requirement might demand something like Aegis controlling a new, very high energy missile. However, like Sea Sparrow, NATO AAW is conceived as a secondary system for ships intended primarily for other purposes, such as ASW. Therefore, NATO AAW has to be relatively small and, it is hoped, inexpensive.

NAAWS has suffered badly from administrative indecision. It was originally part of the abortive NATO frigate program, and it was pushed quite urgently because of fears that Sea Sparrow was becoming obsolete in the face of SS-N-22 and similar weapons. Thus at one point contractors were required to have test systems running in 1989; this requirement in turn tied them to existing hardware, at least on an interim basis. However, as of late 1990, the formal RFP was expected in March 1991. At the same time, the program fell victim to internal warfare over U.S. defense cuts. It was formally deleted from the FY92 budget, but that was most likely only a maneuver, as the secretary of de-

The Westinghouse model of a possible NATO AAW frigate, showing trainable phased-array radars fore and aft, displayed at the U.S. Navy League show in 1990. (Westinghouse)

fense was most reluctant to abandon this multinational program. The deletion from the budget particularly upset the other partners, Canada and the Netherlands, who had stayed with NAAWS (rather than FAMS) despite the collapse of NFR-90. As of late 1990, Spain was still a participant in NAAWS but seemed very likely to choose FAMS instead. However, the Dutch were expected to collaborate with the Germans in developing a new air-defense ship in the late 1990s, and it would most likely be armed with NAAWS. Thus the Germans were likely to reenter the program.

Some of the delay was the result of difficulties in obtaining authority to release U.S. technology to the European allies. That was ironic because NAAWS was originally conceived as a way of transferring Aegis technology to other NATO navies. As of late October 1990, it seemed likely that the NAAWS MoU would have been signed at the end of 1990. At that time technology transfer was still an issue within the U.S. Navy (lists of the relevant technology were submitted in March 1990). Delays in settling the transfer issue delayed the issue of the RFP for 2 months, to early February 1991 (as estimated in October 1990; March 1991 as estimated a few months later). Proponents of a liberal release policy argued that in some areas, such as GaAs-chip technology for future radars, the Europeans were actually in the lead. A Technical Documentation Package was issued in May 1990. When issued, the full RFP had to be answered within 90 days. Reportedly, the MoU would commit the partners to the next phase of the program, Dem/Val and FSED of an interim system. As of late 1990, the U.S. Navy expected to fund only one consortium through Dem/Val in hopes of holding down the cost of the Block 0 system. As of the end of 1990, it was not clear how much a Block 0 missile would vary from Sea Sparrow. The program office claimed that it would be much more capable but would be of the same size, drawing on experience with Standard and with AMRAAM.

The key elements of the NAAWS requirement are the ability to deal with fast surface-skimmers and the ability to handle saturation attacks. The typical building blocks of the system, then, are a horizon-search radar (to pick up surface-skimmers with a very high probability, albeit at relatively short range), a hemisphere-search radar sufficiently accurate for fire control (generally termed an MFR, or multifunction radar), 1 or more electro-optic or infrared sensors integrated with the radars, a combat system core, and a vertically launched missile (for very quick reaction, even at very short range). All the competing consortia include radar and missile builders on both sides of the Atlantic. The consensus seems to be that the most successful (i.e., saleable) NAAWS will have to be adaptable to several quite different radar/missile suites, even though the U.S. Navy is

pushing for definite selections. In turn, the most innovative and important element of NAAWS should be a highly adaptable, modular computer combat system, programmed in the software equivalent of the hardware of the German MEKO frigate. Such flexibility has been most publicly identified with the Ferranti WS500 series (see the Surveillance and Control section), but all of the NAAWS competitors have probably adopted something roughly comparable.

This need for flexibility probably explains the reticence of 2 of the 3 current NAAWS competitors, who have steadfastly avoided mentioning specific sensors or weapons in advertising. The sole exception is Raytheon, which has suggested a developed version of its Sea Sparrow. Reportedly, Raytheon was initially dropped from the NAAWS competition because the company's proposed system was insufficiently advanced over existing ones (i.e., because it was too specific). The company's rejoinder is that anything much less specific cannot possibly meet the NAAWS deadlines (delivery of operational systems by 1998) and that, moreover, full development of a completely new set of systems will break any realistic NAAWS budget.

It is also possible that some developments financed under NAAWS will be applicable to existing ships and systems. For example, Raytheon's newly developed Sea Sparrow, with a new motor and multimode guidance, was intended for launching from the existing vertical launcher; the company argued that up to 64 missiles could be fired from a standard 16-cell vertical launcher (Mk 41). FMC demonstrated "4-pack" Sea Sparrow launching (4 Sparrows in 1 VLS cell) for the first time in June 1988. The company described this success as its contribution to NAAWS (at the U.S. Navy League show, March 1989). In the past, in connection with proposed German ships (presumably Type 123), RCA (now GE) has commented that the ideal weapons suite would be a combination of Standard Missiles and Sea Sparrows in a common vertical launcher.

Several alternative NAAWS configurations have been published. At the U.S. Navy League show in March 1989, GE (which absorbed the RCA division that manufactured SPY-1) showed a possible NATO-frigate design employing a 4-face fixed phased-array radar, with 2 illuminators (similar in shape to the Dutch STIR or STING), and an electro-optical sensor between them. Presumably, the fixed radar would carry out both the horizon and hemisphere-search roles (as SPY-1 does in Aegis ships), and the illuminators would be slaved (as in Aegis). GE would probably use the improved Sea Sparrow as its interim missile, choosing later between new U.S. and European weapons.

Raytheon has published a sketch showing 2 radars, a relatively low frequency rotating unit to detect and track long-range targets (the company's sketch seems to show stacked waveguides), and a higher frequency fixed array to deal with shorter-range targets.

Hughes has suggested the improved version of its TAS Mk 23 as a potential MFR.

The usual published sketch of the NATO frigate shows only

1 MFR, a rotating back-to-back pair of flat-faced arrays atop the ship's tower foremast. That MFR presumably represents Arabel or EMPAR.

The original competing consortia were:

—GE (RCA), with British Aerospace, CSC (which developed the Aegis tactical software), FMC, General Dynamics, Inisel (Spain), Marconi, Siemens, Signaal, and Thomson-CSF.

—Martin Marietta, with Hughes, ITT, Lockheed Electronics, Magnavox, Norden, HSA (Signaal), Bazan, Litton of Canada, AEG, Krupp Atlas, and Plessey.

—Raytheon, with AEG, Fokker, Plessey Radar, Bristol Aerospace, Martin Marietta, ERIA (combat direction software), and MBB.

—Westinghouse, with Hughes Aircraft, LTV, Martin Marietta, McDonnell Douglas, MCR, ORI (analysts), Vitro, Canadian Marconi, MEL, Oerlikon (of Canada), SPAR, AEG, BGT (the German missile manufacturer), Contraves, Dornier, Philips (ELCOMA, of the Netherlands), Bazan, Ceselsa (Spanish radar systems house), Babcock Power (UK), Ferranti, Short Brothers, and Thorn-EMI. This group is called UNISAMS.

By September 1988, the Martin Marietta and Raytheon proposals had been dropped. However, Raytheon protested, and by early 1989 it had been reinstated in the NAAWS program.

At this stage the NATO frigate was still alive, and the main competition was between the French-led FAMS, which was conceived as a stand-alone AAW system, and the U.S.-led NAAWS, which was conceived as an Aegis-like combat system, integrated with most ship sensors and with the ship's tactical data system. NAAWS would also be integrated with the ship's electronic countermeasures. In September 1989 Britain and then France and Italy dropped out of the NATO frigate program, leaving only Spain as a possible participant requiring FAMS rather than NAAWS. At that time France and Italy agreed to join in FAMS. Although Britain was still considering its options, its withdrawal from the NATO frigate made withdrawal from NAAWS likely; that followed in December. The official British reasoning was that the NAAWS schedule ran some years later than what they needed. At that time the Germans, too, withdrew from NAAWS because its capability was beyond their requirements.

These withdrawals left NAAWS as a U.S.-Canadian program with possible Spanish participation. It is still essential as a gap-filler since the United States will have to operate numerous non-Aegis ships against Third World countries increasingly well armed with sea-skimming antiship missiles. At present Aegis is probably the only effective counter to such weapons, thanks to its automated reactions and its very effective main radar.

The withdrawals, particularly by the British, left the contenders in chaos, since British-supplied systems were essential elements of their proposals. The following notes describe the systems, to the extent that information was available late in 1989. At that time it appeared that 2 teams would be chosen for 4-yr demonstration and validation contracts in June 1990.

Unisams was led by McDonnell Douglas Missile Systems. Ferranti was to have supplied the data system, a variant of its System 500. The proposed missile was new, 4 fitting a standard Mk 41 vertical-launching cell, and it used a dual-mode active/passive seeker. A lightweight modular launcher was planned for smaller ships.

The GE team was still built around the FARS radar, but other partners included BAe Dynamics and Marconi Radar.

Raytheon still planned to use its tail-controlled Sparrow derivative, this time with a combined X-band semiactive radar and IR seeker. The planned radars were an S-band MESAR, for volume search and target designation/track, and a smaller Raytheon X-band phased array for target illumination and horizon search. The 2 would be superimposed on a single rotating mounting. In this team, Martin Marietta was expected to provide the core architecture and the vertical launcher; AEG the radar seekers, missile-guidance systems, and ship's combat-systems integration; MBB the fuzes and warheads; ERIA (Spain)

the combat system software; Bristol Aerospace the missile motors and control; and Fokker the missile-control systems and shipboard launchers.

Given the withdrawal of the NATO partners, NAAWS may well be recast as a U.S. Navy program. Alternatively, it may be down-scaled so that it can replace the existing NATO Sea Sparrow on a system-for-system basis.

As of mid-1990, no official RFP had yet been issued. However, the broad concept of NAAWS has not changed. A multifunction radar (MFR) is to be used for both horizon search and fire control. Its beam must be accurate enough to shoot on search, since by definition the system will have little time to shift from detection to firing mode. Ideally, the radar should be accurate enough to control both guns and missiles, although that may conflict with the requirement for rapid search. Current U.S. Navy planning calls for development in 2 stages, first with the existing Sea Sparrow missile but a new command/control core and a new search radar, and then, if money is available, with a new missile. The argument is that even a new missile cannot overcome the inherent limits of existing radar and command/control, whereas better command/control may make the existing missile worthwhile. The current order of priorities, then, is the core (command/control), then the MFR, and only then the missile.

NAAWS apparently differs from previous approaches to the ship-defense problem in integrating all defensive resources, both hard- and soft-kill. Its TEWA, then, must be able to compare, for example, chaff, jamming, missiles, and close-in guns. In theory, NAAWS will be an expert system capable not only of engaging but also of recommending course and speed via a bridge console. To some extent RAIDS (see separate entry) is an approach to this problem.

As of mid-1990, there were 3 active teams: McDonnell Douglas-Westinghouse (Unisams), GE/RCA, and Raytheon. None had a concrete design, at least for public discussion.

McDonnell Douglas had bought the Ferranti System 500 computers it had originally planned to use for the core of its system (System 500 had been used in the concept-exploration phase). At this time it seemed possible that McDonnell Douglas would continue to use System 500 despite the British withdrawal and would buy the associated code. As of 1990, the company was concentrating on evaluating different generic missiles and sensors in standard scenarios, as preparation for the next round of bids. The main test threats are a supersonic high diver and a sea-skimmer. Reportedly, the system is required to achieve a 0.7 probability that the target ship will not be hit.

McDonnell Douglas was also considering using Hughes Ground Systems to develop a new core. Presumably, such a core would be related to the H930 CDS and its successors. Hughes was also attractive because it was already under contract to integrate the TAS radar with combat systems. It, therefore, already had a TEWA and experience in multiweapons assignment.

Unisams was looking at a new Hughes-McDonnell Douglas missile with better performance than Sea Sparrow, using a tri-mode seeker (probably IIR, semiactive, and command). Imaging IR was needed to minimize the miss distance. The projected missile would have been 3 times as fast as Sea Sparrow, shaped like a slimmed-down SM-2 to minimize time constants (i.e., maximize maneuverability).

RCA/GE was also reportedly considering Hughes as a command/control core developer.

Raytheon was still developing a full-up system. As of early 1990, the company was marketing a new line of militarized VAX computers and had developed its own TEWA to run on them, or on its CWS workstation. Presumably this development was fallout from the NAAWS exercise, but it also presented possibilities for future CDS development, possibly in combination with Plessey (Nautis).

◆ NATO Sea Sparrow

See Sparrow (U.S. air-to-air missile) below.

◆ Polypheme-SM

Aerospatiale (France) and MBB (West Germany) are privately developing a submarine-launched, fiber-guided, anti-aircraft missile, Polypheme-SM. As of 1989, the 2 companies claimed that the system could be made operational within 5 yr, should either the French or the German navy fund full-scale development. Range would be 10 km against typical ASW helicopters; presumably, it would be shorter if the missile were fired against higher-performance fixed-wing aircraft. Maximum altitude is

Polypheme-SM emerges from the water, its canister falling away. The after rocket motor is burning. (Aerospatiale)

Polypheme-SM in flight, trailing its fiber-optic guidance link. The forward rocket motor is burning. (Aerospatiale)

5000 m (about 16,000 ft). The 43-kg missile (carrying a 3-kg fragmentation warhead) would be carried in a pressurized 62-kg capsule, which would carry it free of the water. The capsule could be fired at a depth as great as 300 m (about 1000 ft); it would follow a preprogrammed underwater trajectory, at a speed of 15 m/sec, emerging from the water about 1 km from the launch position, to protect the submarine from disclosure of its position.

The missile employs a boost-sustain motor and has 2 flight speeds: 150 m/sec for target search and 250 m/sec for attack. The missile carries 2 separate rocket motors for the 2 phases of its flight. It employs 4 canard steering fins and 4 fixed stabilizing fins at its tail.

Polypheme is compact because, like the U.S. FOG-M land-based missile, it contains virtually no guiding intelligence. Its seeker is optronic, and the seeker output travels down the optical fiber to the launching submarine. The operator aboard the submarine flies the missile to its aerial target.

There are 2 operating modes. If target range and bearing are fairly well known (e.g., if the helicopter is detected by the sound of its blades or by the pinging of its dipping sonar), the missile can search a 3-km-wide path as it flies. Alternatively, if target position is only very approximately known (e.g., by the splash of sonobuoys entering the water), the missile can fly an ascending spiral search pattern, with a radius of 1 km.

Polypheme-SM is interesting because it minimizes the exposure of the firing submarine. However, it still limits the extent to which the submarine can escape after firing. The ideal submarine self-protection weapon is a deterrent to any close approach (for localization) and can be deployed while the submarine runs, and that requires more, rather than less, intelligence inside the missile (infrared guidance is an interesting option here). Otherwise, the use of the missile tends to confirm that a supposed submarine contact is indeed a real one. On the other hand, any effective submarine-launched surface-to-air weapon will greatly reduce the value of current airborne ASW systems.

As of mid-1989, Polypheme-SM is a technology-study program. Hardware development to date has been limited to work with optical fibers; an SS 12 missile has flown 8 km trailing such a fiber. Initially, Aerospatiale used fibers coated with Kevlar, but currently only the hairlike fiber itself is used. Images have been transmitted successfully over a 60-km distance.

◆ RAM (RIM-116A)

See RAM under U.S., below.

◆ VSRAD

A 12–14-month prefeasibility study of a future NATO Very Short Range Air-Defense system began in June 1990. The major partners are Germany, Italy, the Netherlands, Spain, and the United Kingdom, with OTO Melara leading the industrial team reporting to the new Project Group 36. The United Kingdom already has a VSRAD project (see the UK section, below); reportedly, the navies of Germany, Spain, and Italy were planning similar efforts. The current observers are Belgium, Denmark, France, Norway, and the United States. An outline NATO staff target (ONST), already approved by the partners, reportedly calls for a maximum range of about 3 nm. All current hard-kill techniques (cannon, missiles, unguided rockets, lasers, and particle beams) are to be evaluated (the British VSRAD has already chosen a hypervelocity missile, Seastreak).

ISRAEL

◆ Barak I

Dimensions: 170 mm × 2.175 m; span 0.68 m [6.7 × 85.6 × 26.8 in] **Weight:** 98 kg [216 lb]

Warhead: 22 kg [48.5 lb]

Propulsion: triple-thrust (boost/sustain/terminal engagement) rocket **Speed:** 580 m/sec [1900 ft/sec]

Range: 0.5–10 km [550–10,900 yd]

Barak. (IAI)

Israel Aircraft Industries's point-defense missile for small fast attack craft is designed to achieve very short reaction time (time to maximum range less than 30 sec). Barak is vertically launched, and guidance is by automatic command to line of sight. There is also a backup optical command-to-line-of-sight tracker using a laser range-finder. Engagement is fully automatic (with operator veto).

Control immediately after launch is by thrust vanes (which flip the missile over in 0.6 sec, at 25 Gs, i.e., 10 rad/sec), which are jettisoned once the missile has accelerated sufficiently for aerodynamic control. Total angular coverage is from -25 to $+85$ deg (and 360 deg in bearing). The missile maneuvers at 45 Gs. In 1987 Barak was successfully tested against a TOW missile representing a low-cross-section sea-skimmer.

The rocket motor has 3 thrust levels, presumably initial boost (to avoid damaging the launching ship), then high-energy boost, then sustain. There is no conventional proximity fuze because the weapon may often have to engage sea-skimmers; instead, it uses a special Rafael adaptive proximity fuze with an integrated altimeter to control the sensitivity of the downward part of the fuze envelope.

The weapon is carried in 8-missile cells, and 1 control system can accommodate up to 32 missiles. Each vertical launch unit can be split into pairs of 2-8 missiles, either in above- or below-deck launchers. The radar and fire control weigh 1300 kg, and one 8-cell unit weighs 1700 kg. Canister size: $2550 \times 376 \times 300$ mm [$100.4 \times 14.8 \times 11.8$ in]. Barak was conceived for the *Reshef* class, which has a total armament weight of 40 tons. A more conventional self-defense weapon would have consumed a quarter of that weight.

Barak was announced at the June 1981 Paris Air Show, and a model displayed in 1983; tests began in May 1984. Development was reportedly accelerated because of the experience of the Falklands War. The development contract reportedly requires delivery to the Israeli navy from the end of 1988, with the system operational during 1989. However, as of 1988 sea trials were expected only that year, with the system becoming operational in 1990. Chile has bought Barak (the sale was announced early in 1988). Barak will probably arm the Singaporean *Victory* class. Barak will probably also enter Israeli service in 1991. Reported unit price (1987) was \$200,000.

A land-based version of this missile is called Adams. It is described as having a limited ATBM capability, presumably against short-range tactical weapons (such as the FROGs that the Soviets have supplied to many client states).

ITALY

◆ Aspide

Dimensions: 20.3 cm $\times$ 3.7 m $\times$ 80 cm (100 cm in the air-to-air version) [8 in $\times$ 12 ft 2 in $\times$ 2 ft 7.5 in/3 ft 3.4 in]

Weight: 200 kg [485 lb] **Warhead:** 35 kg [77.2 lb]

Propulsion: single-stage solid-fuel rocket

Speed: Mach 4.0 (AAM role) **Range:** 15+ km [16,400 yd]

Aspide is an Italian-designed alternative to the current Sparrow and Sea Sparrow. The airframe is derived from that of AIM/RIM-7H, but the internal systems are new, including an X-band monopulse seeker for snap-up/snap-down firing and for better

countermeasures and clutter resistance. The missile enjoys better endurance than Sparrow, using closed-loop rather than open-loop hydraulics. It also has a new SNIA motor with higher thrust and specific impulse, for greater velocity and range. There is a home-on-jam guidance mode.

Aspide in flight. (Selenia)

Sixteen-missile automatic loader for Aspide. This system and the Canadian Tribal-class Sea Sparrow are the only Western point-defense missile systems not reloaded by hand. (Selenia)

Four-cell Aspide launcher for corvettes. The Orion tracker-illuminator is visible above the launcher. (Selenia)

This missile is widely used as a naval point-defense weapon, and there is also a tactical ground-defense version, Spada. In the naval version, the associated overall system is Albatros, developed by Selenia. Albatros can also accommodate the Sparrow missile and predates the appearance of the navalized Aspide. Aspide's box launcher is much like that of NATO Sea Sparrow, and the substitution of one missile for the other involves only a change in circuit boards and programming, which can even be done at sea. However, unlike Sea Sparrow installations, Albatros/Aspide can accommodate a semiautomatic reloader (and a 16-missile below-decks automatic reloader is under development). There is also a lightweight quadruple launcher for small ships of less than 300 tons (4000 rather than 9000 kg for the launcher, and 1600 kg for the fire-control system); this launcher has been ordered by Ecuador.

The associated radars are usually the Selenia RTN-10X tracker and the Sirio RTN-12X illuminator (but Albatros Mod/10/0, using a Marconi 1802AS, has been developed by Marconi and Selenia-Elsag).

Development of the air-to-air version began in 1969, with trials in 1974-75. Albatros was developed in parallel (initially using the Sea Sparrow missile), with sea tests in 1973. Aspide's production began in 1977, and the first Albatros/Aspide system was exported to Peru in October 1978. The first Italian navy firing of the Aspide missile (from a modified NATO Sea Sparrow launcher) was in July 1979. In 1986 unit price was about \$250,000. By that time over 2000 were on order worldwide, and about 1000 had been delivered.

In 1984 Selenia announced that it was developing a vertically launched derivative of Aspide with an active radar seeker. This derivative was announced as the new Idra missile in April 1985.

However, Idra was dropped in favor of Italian participation in the French-led FAMS systems (for details on Idra, see the previous edition of this book).

In 1986 Selenia began to consider applying the Idra active seeker to Aspide. The active Mk 2 version should enter production in 1995, and deliveries are to begin in 1996.

NETHERLANDS

◆ Sweeper

In April 1988 Signaal and Bofors jointly announced what they describe as a new naval surface-to-air missile system, Sweeper. It appears to be a further development of the 4-missile system jointly announced in 1986 (see RBS 70 below), using the longer-range RBS 70 Mk 2 and the Signaal LIOD electro-optical director. Operation is entirely automatic, no above-deck operator being required.

NORWAY

◆ Norwegian Automatic Short-Range Air-Defense System

NFT has developed this system primarily for small combatants, such as the projected new fast attack boat. This system uses a combined auto-tracker/launcher (3 launch tubes on either side of the director) controlled by a KMT-340 console. The launcher maneuvers on 3 axes, with a maximum elevation of 120 deg. It carries a Ku-band tracking radar and electro-optical trackers. The French Mistral is under consideration as the weapon. The KMT-340 console is a reduced version of the new MSI-340 CDS planned for the new Norwegian fast attack boat.

SWEDEN

◆ RBS 70 (Rayrider)

Dimensions: 10.6 cm × 1.32 m; span 32 cm [4.2 × 52.0 × 12.6 in]

Weight: 15 kg [33 lb] (system weight 250 kg [551 lb])

Warhead: 1-kg prefragmented (with tungsten pellets) using impact and laser proximity fuzes [2.2 lb]

Propulsion: boost-sustain rocket (booster burns only in launch tube; sustainer ignites at a safe distance)

Speed: Mach 1.0+

Range: 5,000 m [5500 yd]; 6000 m in the Mk-2 version. Height coverage is 3000 m [9480 ft].

RBS 70 Missile Mk 2. (Bofors)

Rayrider is the naval version of the Bofors laser-guided infantry weapon; RBS 70 is currently used on board Swedish *Land-sort*-class minesweepers and Finnish *Helsinki-II*-class fast attack craft. The missile is a laser beam-rider; Bofors claims that the missile is unjammable because it receives its information from the launcher, not the target. Laser beam-riding automatically confers forward-aspect capability. In contrast, most short-range SAMs, which home on a target's infrared radiation, typically fly toward a target's tail. Thus they cannot hit an approaching attacker. Only very sophisticated infrared weapons, such as Stinger, can match RBS 70's forward-hemisphere performance. The laser transmitter/tracker is already gyro-stabilized for use on light trucks and is, therefore, automatically adaptable to a moving ship. The current standard installation is a single missile-launcher tube on a pedestal, which also carries the operator's seat. Reaction time is 4-5 sec.

The current RBS 70+ (Mk 2) version has a greater range and a better laser receiver, increasing the defended area by 30-50%. Mk 2 uses digital guidance (which takes up less volume than the earlier analog electronics and, thus, leaves more space for a warhead), a 50% larger warhead (shaped charge plus fragmentation pellets), and a larger sustainer. Finally, Bofors describes Mk 2 as armor-piercing and, therefore, capable of dealing with armored missiles and aircraft such as helicopters (and, presumably, thin-skinned armored vehicles). Mk 2 is fully interchangeable with Mk 1. Early in August 1988 Bofors tested a Mk 2 against a sea-skimmer approaching at an altitude of 5 m [about 16 ft]. The target was destroyed at a range of 1800 m. The target's dimensions were 40 cm [16 in] in diameter and 4.5 m in length. Mk 2 entered production during the winter of 1988-89. Effective range is 7000 m.

In 1986 Bofors and Signaal (HSA) announced a more elaborate system, combining a quadruple RBS 70 launcher with the pedestal, processor, and console of the Signaal LIOD director. Targets would be designated by 1 or 2 optronic designators, each carrying a coarse sight and a 7 × 50 binocular. Targets would be tracked by the Signaal LIOD in the launcher itself, using a

Sweeper launcher. (Bofors)

daylight television with a 3-deg FOV, with an effective tracking range of 11,000 yd (and effective up to a target speed of 875 yd/sec). The 2-pod quadruple launcher weighs 425 kg, plus 85 kg for each target designator and 375 kg for the control console.

A new version, RBS 90 (formerly RBS 70M Nightrider), combines the Mk 2 missile with a new remotely controlled twin launcher with a laser transmitter and TV and IR cameras on board. Although RBS 90 is intended for land use, it has obvious naval application.

Work on the basic missile began in 1967, and Bofors received a development contract in 1969 and a production contract in June 1975. The naval version was tested in February 1984, and a vertically launched version was demonstrated on 9 September 1986 (tests completed November 1986). In 1988 the estimated cost per missile was \$90,000–\$100,000. The Iranians used RBS 70 extensively during the Gulf War and reportedly shot down about 45 aircraft with it.

SWITZERLAND

◆ ADATS

Dimensions: 6 × 81 in **Weight:** 113 lb

Warhead: 26.5-lb frag-HEAT; active laser proximity fuze and impact fuze

Propulsion: solid-fuel rocket **Speed:** Mach 3

Range: 1000–8750 yd; to altitude of 16,500 ft

The Oerlikon Air-Defense Antitank System was designed for land operation, but reportedly the Thai navy is considering it. As its name implies, ADATS provides substantial surface-to-surface capability in addition to low-altitude air defense. Oerlikon is the system integrator; the missile is made by Martin Marietta.

The missile achieves its dual capability by laser beam-riding, with receivers in 2 of the tail fins; the burden of dual-purpose guidance falls on the optronic director. The current optronic package is similar to that of the AH-64 attack helicopter. The missile has dual fuzing—impact for antitank, laser proximity (4 lasers and 4 receivers) for antiaircraft. Missiles are delivered in sealed 143-lb containers, 9.45 × 86.6 in.

The standard ADATS turret, including 8 missiles, weighs 9920 lb. Presumably, this is much the same as the weight of a possible shipboard version. The stabilized turret carries a FLIR, a television, an NeYAG laser range-finder, a CO₂ guidance laser, and an optronic missile tracker; in addition, it carries a Contraves Italiana X-band, dual-beam, pulse-doppler, TWS radar for initial target acquisition. The latter searches out to a range of about 22,000 yd and up to an altitude of about 16,000 ft. The manufacturer claims that, encountering 8 aircraft flying at 900 km/hr at 2-sec intervals, the system can detect them at 14,000 yd and kill 5 before they fly over, and 3 more as they depart.

Development began in 1979, and missile trials in June 1981. The first full-system trial followed in 1982. ADATS has been adopted by both the Canadian and U.S. armies (the latter as its LOS-FH).

About August 1990 Oerlikon sold the ADATS system to Martin Marietta (which had developed the missile), retaining marketing rights outside North America. At that time it was uncertain whether the U.S. Army would actually purchase the system that it had selected.

TAIWAN (GOC)

Although current service missiles (Sea Chapparral and Standard) are all of U.S. origin, there are 2 indigenous programs for possible future naval missiles, Tien Chien and Tien Kung.

Tien Chien (Sky Sword) is a generic term for air-to-air missiles. Tien Chien I is an IR missile comparable to Sidewinder AIM-9L/M, and a prototype has been fired from a ship, probably using a modified Sea Chapparral launcher. Tien Chien II is broadly comparable to advanced versions of Sparrow.

Tien Chien I is being developed to replace the current AIM-9N/P; it reportedly enjoys better acquisition and tracking at low altitude and near the sun and has a seeker similar to that of the AIM-9L. Compared to AIM-9L, it has double-delta canards with a higher aspect ratio. Production is to begin in 1990, and 700 are planned, initially for fighters but probably later for shipboard use.

Tien Chien II is a longer-range missile, initially conceived in 3 versions: medium-range semiactive radar, active radar, and ARM. The last version no longer enjoys a high priority, although seeker technology demonstration work is continuing. The semiactive version is comparable to AIM-7M, and in 1990 it is nearly at the end of full-scale engineering development. The airframe and motor are based on those of AIM-7F, but Tien Chien II is to have a higher-thrust, impulse, boost-sustain motor and better aerodynamics. The inverse-monopulse seeker has been test-flown (although the missile as a whole has not), and reportedly the missile will have a digital autopilot and on-board digital processor similar to those in AIM-7M. The warhead will probably be blast-fragmentation with a laser proximity fuze.

The semiactive missile is considered an interim step toward full active homing, as in the U.S. AMRAAM. An initial version will replace the semiactive seeker in the semiactive version with an X-band active radar, but will lack any data link. Effective range will be about 20 nm. The ultimate version is to incorporate a data link controlling the missile in mid-course via a new controllable autopilot, as in AMRAAM. In its airborne version, the missile will be controlled by a variant of the U.S. APG-67 radar, which has a 30-nm look-up range and a 22-nm look-down range. Missile speed has been reported as between Mach 3 and Mach 6, depending on trajectory.

As of 1990, it was expected that the interim active version would be ready about 1994, and the ultimate version about 1996–97.

The Taiwan navy has expressed interest in the weapon as an alternative to NATO Sea Sparrow for the new frigates now (1990) planned. These ships were initially to have been French FL 3000s equipped with the French Tavitac 2000 tactical data system and with vertically launched Sea Sparrows. However, early in January 1990 the French government canceled the sale of the ships, and it is no longer clear what the design ultimately adopted will be.

The other major anti-aircraft missile program is Tien Kung (Sky Bow), the surface-to-air series. Tien Kung I is similar in outline to the U.S. Patriot but employs semiactive homing derived from that of Improved Hawk. Although Hawk homes continuously, Tien Kung reportedly uses a mid-course data link with semiactive terminal homing. It would then be more like the U.S. New Threat Upgrade or even the Aegis system. The current land-based version employs the General Electric (RCA Division) ADAR-2 phased-array radar, which is linked to several illuminators.

Tien Kung I is about the same size and shape as Patriot; the latter is 16 × 204 in and 2200 lb; the blast-fragmentation warhead weighs 200 lb. Patriot's slant range is 60 km and maximum altitude is 78,750 ft. Like Hawk and Patriot, Tien Kung I has a dual-thrust rocket motor. It has a blast-fragmentation warhead probably comparable in size to that of Patriot. Speed at burn-out is Mach 4 to Mach 5, and maximum range is about 35 nm, with an effective ceiling of 60,000+ ft. Like Patriot, Tien Kung I is designed for very high maneuverability, reportedly for sustained 30–35-G maneuvers, with an ultimate limit of 60 Gs.

The missile is fired from a quadruple launcher, and a 16-rd vertical launcher is being developed. The latter may ultimately equip Taiwan navy frigates. The land-based version is currently operational using Improved Hawk fire control.

An extended-range version, with a separate booster rocket, is being developed as Tien Kung II. This is a less ambitious version of the original program, which included active terminal radar guidance and an integral rocket-ramjet motor.

As of mid-1990, Tien Kung II has been redesigned with a ramjet power plant. Trials of the original rocket-powered version were disappointing, because of bubbles in the propellant. Taiwan, therefore, bought Bloodhound missiles from Singapore (to acquire superior solid-fuel technology), only to find that they, too, suffered from the internal bubble program.

As for current programs, the SM-1 version aboard Wu-jinn III (modernized *Gearing*)-type destroyers is now operational. For details of this system, see the description of the Modular Combat System (MCS), a variant of the U.S. H930, under tactical data systems in the Surveillance and Control section of this book. In October 1989 a Wu-jinn III successfully fired an SM-1 against a Beech drone at a range of 27 km at medium altitude. This success followed some initial failures. The main problem seems to have been breaking radar track. Given the nature of the MCS, that problem may be due to the limited effective data rate through the data bus, and thus to excessive dependence on extrapolation.

USSR

◆ SA-N-1 Goa

Dimensions: 37 cm × 6.1 m; span 1.2 m; booster diameter 55 cm and span (folding fins) 2.3 m [14.6 × 240 × 47 in; 21.6/90.6 in]
Weight: 950 kg [2090 lb] **Warhead:** 60 kg (132 lb)
Propulsion: separate booster (burn time 3 sec) and sustainer (19 sec); boost-glide flight
Speed: maximum Mach 3.5
Range: 18.3 km, minimum 2.4 km; altitude limits 45 m to 18.3 km [2600–20,000 yd; 150–60,000 ft]

Data are for the land-based SA-3.

A navalized version of the land-based SA-3, SA-N-1 was the first Soviet naval surface-to-air missile to enter widespread service. The land-based SA-3 is known as Neva (S-125) in Soviet service and was developed by the Lavochkin design bureau. SA-3 was conceived as a low-altitude complement to the SA-2, which had been designed primarily to attack bombers at high altitude. SA-3 was the first Soviet surface-to-air missile to use solid fuel for both stages, a consideration that would have made the missile much more attractive than the massive SA-2 for naval use. Prototype testing of SA-1 began at Sary Shagan in 1959, and that missile became operational in 1961.

The naval missile, SA-N-1, is designated M1 Volga-M in Soviet service; the Soviets may use the name Volga for the missile itself within the land-based Neva system. The first test platform

Typical area-defense missiles. Top to bottom: Masurca, Terrier, SM-2(ER), SA-N-6, SA-N-3, SA-N-1, Tartar, SM-1(MR), Sea Dart. (*Ships of the World*)

was the Kotlin-class destroyer *Bravyy*, which ran trials in June 1962. This system arms Kashin-class destroyers and Kynda- and Kresta-I-class cruisers. The roughly contemporary SA-N-2, a navalized SA-2, was employed only on board one now-discarded ship and seems to have been an unsuccessful experiment.

SA-N-1 is command-guided, with 1 double Peel Group director per twin-armed launcher. The director can, therefore, engage only 1 target at a time; the doctrine is presumably to fire 2

An SA-N-1 missile on its dual launcher. (TASS from SOVFOTO)

weapons per target. The system presumably operates as command to line of sight, measuring an error between the line of sight to the missile and to the target, and sending correction signals. That scheme is probably also characteristic of SA-N-3, -4, and -9.

The missile has a canard configuration, with relatively large fixed wings, and there is a short booster, whose fins fold out as the missile leaves its launcher.

SA-N-1 (like all other Soviet naval surface-to-air missiles) is credited with a secondary antiship role. As estimated in 1973, surface-to-surface range is 3–9 nm. This missile (and the other Soviet naval SAMs) is normally proximity fuzed; design for antiship attack would require an additional impact or delayed-action fuze.

Standard magazine capacity per launcher is 16, the missiles being carried in two 8-missile race-tracks.

◆ SA-N-3 Goblet

Dimensions: 60 cm × 6.1 m; span 1.4 m [23.6 × 240 × 55.1 in]

Weight: 545 kg [1200 lb] **Warhead:** 80 kg [176 lb]

Propulsion: boost-sustain rocket motor **Speed:** Mach 2.5

Range: 32,800 yd (improved version, in *Kiev*, 60,100 yd) (altitude 300–80,000 ft)

SA-N-3 missile being launched, with another on the launcher. (*Ships of the World*)

SA-N-3 is unique among Soviet naval surface-to-air missiles in having no army equivalent; reports that Goblet was related to the semiactive SA-6 proved erroneous. SA-N-3 is command-guided (Head Lights is the radar director), with 1 director per twin launcher. The missile has shallow delta wings, perhaps adopted for lengthened surface-to-surface range, for something approaching dual-purpose performance. The rear fins carry fixed antennas that probably carry the command link.

Reportedly, SA-N-3, like SA-N-1, was developed by the Lavochkin/Grushin design bureau, and a proposal for this weapon was prepared for Khrushchev in 1961.

In 1973 SA-N-3 was credited with a surface-to-surface range of 2–20 nm.

Missile capacity per launcher is 36 (it may be 22 in some ships).

◆ SA-N-4

Dimensions: 21 cm × 3.2 m; span 64 cm [8.2 × 126 × 25.2 in]

Weight: 168 kg [370 lb] **Warhead:** 18 kg [40 lb]

Propulsion: boost-sustain rocket (burn times 2 and 15 sec)

Speed: Mach 2+

Range: 13 km (minimum 1.6–3 km) [14,200 yd; minimum 1750–3300 yd]; altitude limits 30–20,000 ft

The Soviet designation of this point-defense missile system is Osa-M; the Soviet launcher designation is ZIF-122. SA-N-4 is a naval equivalent of the land-mobile SA-8 (Gecko). Apparently the naval version entered service first. SA-N-4 is broadly comparable to the U.S. Sea Sparrow or to Crotale Naval. Missiles are housed nose-down in the protective silo. The twin-arm

Short-range naval air-defense missiles. Top to bottom: Crotale Naval, Mistral, Sparrow, Aspide, RAM, Barak, RBS 70, Sea Cat, Sea Wolf, SA-N-4. (*Ships of the World*)

launcher is normally housed; it emerges before firing and retracts to pick up reloads. Missile capacity per standard 4.2-m diameter silo is 20, on 4 revolving drums, each carrying 5 rnds. The nose-down position reduces the distance missiles must be lifted into firing position and may be required for fuzing before firing. This arrangement would also simplify protection against a cook-off, since all that would be required would be to open the door to vent.

SA-N-4 is command-guided (by the Pop Group radar) and can be used against surface targets.

The missile details above refer to the land-based equivalent, SA-8. At the Defense Services Asia Exposition (Kuala Lumpur, March 1990) the Soviets provided official details of the land-based missile. Detection range of the land-based radar (similar to, but not identical to, Pop Group) was given as 35 km, tracking range as 25 km, and missile range as 1.5–10 km (1640–10,900 yd); altitude range was given as 10–3500 m (33–11,500 ft). Firing rate was given as 1 missile every 45 sec, and ready-to-fire time as 26 sec.

In 1973 SA-N-4 was credited with a surface-to-surface range of 1.5–4 nm. Reportedly, the Soviets frequently exercise this capability.

SA-N-9 is the replacement for this system.

SA-N-4 missiles on their twin-arm launcher.

◆ SA-N-5 Grail

Dimensions: 70 mm × 1.34 m [2.76 × 52.8 in]
Weight: 9.2 kg [20.3 lb]
Warhead: 1.1 kg (370 g RDX/AP) [2.4/0.82 lb]
Propulsion: boost-sustain rocket
Speed: 385 m/sec (Mach 1.13) [1260 ft/sec]
Range: 3.6 km; min 800 m, altitude limits 50–3500 m [875–3900 yd, 165–11,500 ft]

A standard quadruple SA-N-5 mounting. Many Soviet submarines carry single SA-N-5 tubes.

SA-N-5 is a naval version of the ubiquitous SA-7 shoulder-launched surface-to-air missile. Grail is either hand-held or fired from a special quadruple launcher. SA-N-5 is widely distributed on board Soviet patrol and amphibious craft, much as the U.S. 20-mm gun once appeared wherever space was available. Many Soviet submarines reportedly carry 1 or more in the sail, for self-defense when surfaced. Compared to the U.S. Stinger, SA-N-5 is reportedly less effective against anything but a hot tailpipe and is easier to counter.

The basic missile is called Strela or 9M32 in Soviet service; development was reportedly inspired by the revelation of the U.S. Redeye in 1959. The naval version is called Strela 2M in Soviet service.

The SA-7 is produced in China as HN-5; HN means Hong Nu, or Red Cherry. The current HN-5A is an improved HN-5 with a more powerful warhead and a better seeker, the latter for greater detection range and better discrimination against clutter. Slant range is 0.8–4.4 km. This missile is carried on board fast attack craft and small auxiliaries.

For some time there have been reports of Soviet interest in submarine antiaircraft missiles. In 1990 it was reported that Typhoon and Kilo-class missiles carry a 4-ft-diameter pressure-proof container that can be extended upward. The container carries 12–18 SA-N-5 or -8 IR missiles, and the report claims that a hinged blast deflector is clearly visible on the sails of both types of submarine.

◆ SA-N-6 Grumble

Dimensions: 45 cm × 7 m [17.7 × 276 in]
Weight: 1500 kg [3300 lb] **Warhead:** 90 kg [198 lb]
Propulsion: rocket **Speed:** Mach 6
Range: 100 km; max altitude 30.4 km, min altitude 300 m [about 109,000 yd, 984–99,700 ft]

SA-N-6 is a naval version of the land-based SA-10 area-defense missile. The land-based weapon was reportedly designed in the late 1960s or early 1970s to deal with a new generation of high-speed threats, presumably including the new U.S. SRAM short-range ballistic stand-off bomber missile. In naval service, SA-N-6 supersedes the SA-N-3 area-defense missile and provides (in theory) the ability to counter much faster threats and, probably, pop-up threats (thanks to the vertical launcher). However, because Grumble almost certainly cannot engage incoming threats around a 360-deg arc, SA-N-6 is not a true anti-saturation system like the Aegis system.

Reportedly the missile is extremely energetic.

The land-based system was developed by the Grushin design bureau, and tests began in 1972. In land service, the missile is associated with a large S-band surveillance-and-tracking radar (Big Bird), a pulse-doppler target tracker, and a flat-plate X-band

An SA-N-6 launcher on board the cruiser *Marshal Ustinov*. In contrast to Western vertical launchers, only 1 missile can be launched at a time (only 1 section opens); the triple circular plates over other missile positions are apparently blow-out plates. (S. Zaloga)

control radar. It seems likely that the naval Top Dome radar combines the tracking and missile-control functions in a single device, and that the Big Bird surveillance/acquisition function is carried out by Top Sail or a similar 3D search set.

The naval test ship, the cruiser *Azov*, appeared in 1977. SA-N-6 is the primary anti-aircraft armament of *Kirov*- and *Slava*-class cruisers. Missiles are carried in 8-rnd vertical revolver launchers. Since each Top Dome director covers only a limited arc, and since all the missiles can fly in any direction, it seems likely that each director can control weapons against the maximum number of targets. In that case the 12 missile launchers on a *Kirov*-class cruiser would suffice to deal with 6 targets (on the usual Soviet basis of 2 missiles per target), and each director would be able to engage up to 6 targets simultaneously, over a limited arc.

A Soviet brochure describing the equivalent land-based system (S-300 PMU) was released late in 1990. The system is credited to the Almaz design/production bureau. It consists of a command vehicle and 3 launcher vehicles, each carrying 12 missiles, i.e., it is equivalent to the 12 launchers (and 1 of the Top Dome radars) of a *Kirov*-class cruiser. The brochure claims that the radar can handle 6 targets (2 missiles per target) simultaneously and that it can intercept air targets at any operational altitude above 25 m [about 80 ft], i.e., well above sea-skimmer altitude. The single-stage missile uses solid fuel and has a fragmentation warhead; it is cold-launched and ignites well above the launch canister.

◆ SA-N-7 Gadfly

Dimensions: 40 cm × 5.6 m, span 1.2 m [15.9 × 220 × 47.2 in]

Weight: 650 kg [1433 lb] **Warhead:** 80 kg [176 lb]

Propulsion: solid rocket **Speed:** Mach 3

Range: 30 km, min 3 km [3300–33,000 yd]; altitude limits 100–46,000 ft

SA-N-7, a navalized SA-11, is the first Soviet naval semiactive missile. SA-11 was itself derived from SA-6, a semiactive weapon inspired by the U.S. Hawk. As in the U.S. Standard system, SA-N-7 uses a single-arm fast-firing launcher, but it uses multiple Front Dome illuminator-trackers located near each launcher. *Sovremennyy*-class destroyers are arranged so

The destroyer *Sovremennyy* fires an SA-N-7 missile. (West German MoD)

An SA-N-7 missile on its launching rail on board a *Sovremennyy*-class destroyer. The resemblance to the U.S. Standard Missile is apparent. (German Ministry of Defense)

that 2 Front Domes are located on each side of each launcher, with 2 more on the sides of the ship near the forward launcher. An electro-optical device, presumably associated with the system, is located on each side near a Front Dome near each launcher. At least 2 Front Domes, therefore, bear on each heading (3 on the broadside). This pairing would seem to correspond to the previous Soviet practice of providing 2 missiles per target (on 2 launcher arms of a slow-firing launcher). However, the 2 launchers must share 1 Front Dome when they engage targets approaching from directions near the broadside. Presumably, the Soviets could not adopt the typical U.S. solution, to place the illuminators on the centerline, because these ships are extremely limited in centerline space. The trials ship, *Provornyy*, has 8 Front Domes, giving her a pair on each quarter. Presumably, *Sovremennyy* is too short to allow for this arrangement (the after position equivalent to 1 of the 2 forward Front Dome positions is occupied by the Light Bulb data link antenna).

Reportedly, SA-11 uses an energy-efficient up-and-over trajectory similar to that of SM-2. That would seem to imply the

use of a data link, in which case the SA-N-7 system would be somewhat equivalent to the U.S. NTU. Reported characteristics include a maximum speed of Mach 3.0 and the ability to maneuver at 23 Gs. These figures compare with Mach 2.5 and 15 Gs for SA-6.

The land-based SA-11 appeared about 1979; the naval test installation (on board the destroyer *Provornyy*) appearing in 1981. The missile itself is similar in external configuration to the U.S. Standard Missile series. Only 1 ship per year is being built to accommodate this missile.

The standard launcher holds 20 (also reported as 22) missiles. Its Soviet designation is probably 3S90. The Soviet name for this system is their word for "Tornado."

◆ SA-N-8 Gremlin

Dimensions: 75 mm × 1.4 m [2.9 × 55.1 in]
Weight: 10.5 kg [23.1 lb] **Warhead:** 2 kg [4.4 lb]
Propulsion: boost-sustain rocket **Speed:** 600 m/sec [1970 ft/sec]
Range: 6 km, min 600 m; altitude limits 10 m and 5500 m [660–6600 yd; 33–18,000 ft]

A follow-on to SA-N-5, SA-N-8 uses the next-generation Soviet hand-held weapon, SA-14. Reportedly SA-14 introduces a more sensitive IR detector but still lacks full forward-aspect capability and, thus, does not quite compare with the U.S. Stinger. The next type, SA-16, reportedly can attack an approaching target and is probably also in naval service.

This weapon apparently entered service about 1980.

The Soviets displayed SA-16, which they designate Igla (Needle), at the Defence Services Asia Exposition at Kuala Lumpur in March 1990. The IR seeker has a 40-deg FOV, compared to the 5 deg of earlier equivalents (i.e., it probably uses an imaging IR seeker), and maximum range is 5000 m [5500 yd]. Targets can be engaged at altitudes of 10–3500 m [33–11,500 ft], and maximum target speed is 360 m/sec [700 kt]; average missile speed is 570 m/sec [1100 kt]. Reaction time is 5 sec.

◆ SA-N-9

Dimensions: 20 cm × 3.5 m [7.9 × 103 in]
Weight: 200 kg [441 lb] **Warhead:** 20 kg [44 lb]
Propulsion: boost-sustain rocket **Speed:** Mach 3
Range: 15 km; maximum altitude 12 km [16,400 yd; 39,000 ft altitude]

This vertically launched missile is the successor to SA-N-4. SA-N-9 first appeared in the destroyer *Udaloy* and is to be fitted in the cruiser *Frunze*, the carrier *Novorossisk*, and presumably in other future construction. SA-N-9 is found on board the carrier *Baku*. Reportedly, SA-N-9 is a naval version of the land-based SA-15, which has superseded SA-8 in Soviet ground forces. Data above describe SA-15.

The associated radar director is Cross Sword.

Four SA-N-9 revolver launchers on board a *Udaloy*-class destroyer. Presumably, they are loaded via the large centerline hatch. The shrouded objects farther forward are twin chaff launchers. (Sea Power)

At San Diego in 1990 the Soviets stated that each SA-N-9 vertical launcher loads a missile into the central position and fires it from there; it can fire its 8 missiles within about 1 min.

A Soviet brochure describing an equivalent land-based system (Tor) was released late in 1990. The system is credited to the Antey design/production bureau. The vehicle-mounted Tor carries 8 vertically launched missiles in a rotating turret, with a planar radar and a search radar on the same turret. Neither really resembles any element of Cross Sword, but performance is presumably comparable. Two system operators sit at a pair of consoles carrying a large CRT (presumably for the search radar), a medium CRT (presumably for the EO adjunct), and a small CRT (at the other operator position, presumably the display for the engagement radar).

In this system the C-band pulse-Doppler/pulse-compression search radar has a range of 25 km, and its beam is 32 deg high (covering 0–32 or 32–64 deg; no horizontal beamwidth is given in the brochure). It can acquire up to 48 targets, initiate tracks on 10, and evaluate threats automatically. The K-band pulse-Doppler/pulse-compression, phased-array, tracking radar operates over a 15 × 15-deg sector, tracking 2 targets simultaneously at velocities of up to 700 km/sec [1380 kt]. The complementary EO system can detect targets at 20 km.

Reaction time from the first target detection is 5–8 sec.

The missile has a maximum range of 12 km [13.1 kyd] and can engage at altitudes between 10 and 6000 m [33–19,600 ft]. Maximum missile speed is given as 850 m/sec, and the fragmentation warhead (which uses a proximity fuze) weighs 15 kg [33 lb].

◆ SA-N-10

This lightweight twin-arm automatic launcher for IR-guided missiles is found only on board the nuclear-powered auxiliary SSV-33. The missile may be SA-N-8 (SA-14 or -16).

SA-N-10 launcher (upper center) on board the intelligence-gathering ship SSV-33. It is 1 of 3 on board (2 are aft). Immediately abaft it are a Kolonka remote visual sight and a pair of Tin Man remote optronic devices; forward is a 76-mm gun. The launcher presumably reloads automatically from below. (Sea Power)

◆ SA-N-11

This is the missile component of the CADS-1 system described in the gun section below. The missile, launched from a dispos-

able tube, is a navalized SA-19. The mount carries up to 8 missiles, plus guns. The missiles may be auto-reloaded from a below-decks magazine, perhaps in analogy to the standard Soviet bombardment rocket launcher.

UNITED KINGDOM

◆ Javelin/Starstreak

Dimensions: 3 × 54.7 in (fin span 10.8 in) **Weight:** 28 lb

Warhead: 6 lb (1.3 lb HE) **Speed:** Mach 1

Propulsion: boost-sustain rocket

Range: 5000 yd vs. jet aircraft, 6000 vs. helicopter; minimum range about 500 yd; effective altitudes 30–10,000 ft

Data above apply to Javelin.

These are hand-held anti-aircraft rockets comparable in role to the U.S. Stinger, the Soviet SA-7, and the Swedish RBS 70. Javelin can be used for small ship's self-defense; the manufacturer, Short Brothers, has tried from time to time to sell multiple lightweight mounts. The Royal Navy first purchased Javelin in June 1984, following trials on board HMS *Phoebe*. A 5-rnd mount is being developed. Sea Javelin was formally announced in September 1985, and in November 1986 it was revealed that British minesweepers in the Persian Gulf had been armed with Javelin for self-protection. Javelin is also carried in a 3-barrel launcher on the Omani royal yacht. No GWS designation has been announced. The Royal Navy used the predecessor missile, the Short Brothers Blowpipe, as an emergency point-defense weapon during the Falklands War and may have deployed some to the Persian Gulf. However, none are currently (1990) deployed, and on land British Blowpipes have been limited to Territorial (reserve) forces.

Blowpipe has survived as a war-reserve weapon. It was carried on board Canadian warships assigned to the Persian Gulf in August 1990; these ships were also fitted with elderly Boffin single 40-mm mounts (which were intended for the new Canadian coastal mine-countermeasures craft). The Canadians later bought Javelins to supplement or replace their Blowpipes.

The Javelin missile is command-guided to line of sight, the aimer using a sight and thumb controls to maintain the apparent coincidence between missile and target. The missile is auto-

Triple Javelin. (Short Brothers)

matically gathered into the FOV by an infrared sensor, and that process reduces minimum range to 300 yd. Time of flight to full range is 14 sec. Javelin uses semiautomatic command-to-line-of-sight control, the operator merely keeping the target in the aiming sight, and the missile being tracked automatically. This scheme increases accuracy and reduces minimum intercept range. Javelin also has a higher impulse motor for greater range (5.5 km [6000 yd]), and a blast-fragmentation rather than a shaped-charge warhead (2.72 vice 2.2 kg). Dimensions match those of Blowpipe, except that the missile is slightly heavier, and the total system, including the clip-on aimer, weighs 24.1 rather than 20.25 kg.

As of 1988, estimated costs per missile were \$8000 for Blowpipe and \$12,000 for Javelin. Blowpipe was sold to at least 14 countries, and production probably amounted to about 36,500 rnds, with one clip-on aiming unit for every 5–10 mds.

The successor missile is Starstreak, which uses a boost-sustain rocket to attain Mach 4.0 and has a range of 7 km (7700 yd); minimum range is about 300 m. Dimensions are 127 mm × 1397 mm (launch tube diameter 274 mm). No weight figure is available, but the manufacturer has tried to keep total on-shoulder system weight below the Javelin's 24.3 kg. Unlike any previous British anti-aircraft missile, Starstreak fires 3 separate warheads (darts), each about 2 × 45 cm, which are described as both explosive and kinetic-energy penetrators. Each carries

This model of a naval Starstreak (Seastreak) mounting was displayed by Short Brothers at RNEE in 1989. (Author)

Javelin on shipboard. (Short Bros.)

about 1 kg of high explosive. Since the motor is Javelin-derived, it would appear that the very high speed is achieved by using very light darts, perhaps analogous to the use of sabots in conventional guns.

The Starstreak command unit contains 2 laser diodes, 1 scanning horizontally and 1 vertically, to establish a 2D matrix of beams pointing toward the target. The darts are, in effect, beam-riders, using steerable fins to hold formation within this matrix. They are designed to penetrate before exploding. Guidance is semiautomatic, the operator placing a stabilized aiming circle on the target using the continuous-zoom telescope. The operator tracks it briefly to establish azimuth and elevation lead angles before firing, then keeps the circle on the target until the darts hit.

Short Bros. displayed a private-venture naval version, Sea Streak, at the RNEE exhibition in 1989. A 1-ton powered stabilized mounting carries 24 missiles, a mm-wave surveillance radar (scanning in both bearing and elevation to detect targets at up to 15-km range) at its head, electro-optical tracker and guidance sensors on 1 side, and radar tracker and guidance sensors probably operating in mm-wave) on the other. The surveillance radar provides threat warning and evaluation, and the entire system can operate automatically. Salvo size is based on automatic threat evaluation, e.g., 1 missile against an airplane, or 3 against an antiship missile. The naval Starstreak missile would differ from the land-based version in having a single-stage motor and boost-phase guidance.

◆ Sea Cat (GWS 20, 21, 22, 24)

Dimensions: 7.5 × 58.3 in; span 25.6 in **Weight:** 138 lb
Warhead: 45 lb (38-lb HE) in Mod 1; Mod 0 is a 31-lb continuous-rod warhead (5-lb HE); both mods have both impact and IR proximity fuzes. **Propulsion:** boost-glide
Speed: Mach 0.6 (average at the end of boost)
Range: 5000 yd, minimum 1500 yd; max altitude 3300 ft

Sea Cat was the first point-defense missile to enter naval service. Sea Cat was conceived (by Short Brothers and Harland) as a 1-for-1 replacement for the existing twin 40-mm Bofors gun and was based on the Malkara antitank missile. Sea Cat is command-guided by an operator using a joystick (Mk 20 Visual Guided Weapon Director); the operator first captures the missile after launch using sighting binoculars, then tracks it to the target. This version is used by Australia (early River class) and Nigeria (*Erin'ni* class).

GWS 21 is controlled by the Type 262 radar originally developed for 40-mm gun control. This version is used by Indonesia (Tribal class).

A quadruple Sea Cat launcher on board the British frigate *Argonaut*, 1975. (U.S. Navy)

GWS 22 employs a modified radar director originally designed for medium gunfire control, MRS 3 (the British equivalent of the U.S. Mk 56), with Type 904 radar and a Type 323-series closed-circuit television. In this MEASL system, ordered by the Royal Navy in 1972, the television, which is slaved to the target-tracking radar, tracks the missile automatically. This version is used by Chile (County class and *Leander* class), India (*Leander* class), New Zealand (*Leander* class), Pakistan (County class and *Leander* class), and the United Kingdom (surviving non-Sea Wolf *Leanders*).

GWS 24 employs the WSA-4 FCS with Type-912 radar (*Amazon*-class frigates). This version is also used by Brazil (*Niteroi* class).

Sea Cat could also be controlled by the Contraves Sea Hunter, the Selenia NA-9, and the Signaal M45 systems. Only the last survives in Australia (later River class), Chile (*Almirante Williams* class), India (some *Leanders*), and Indonesia (*van Speijk* class). The Sea Hunter version was adopted by Iran, but Sea Cat was removed from her Vosper corvettes (replaced by Soviet-type 23-mm cannons).

Sea Cat was modified in 1977 with a special altimeter, for the antiship-missile-defense role; Sea Cat carried out sea-skimming trials late in 1980 and was ordered (as a target) in September 1980.

The standard launcher carries 4 missiles, with the command-guidance antenna in the center. The launcher weighs about 6600 lb. A lightweight (2800 lb) 3-missile launcher was adopted by the Iranian and Nigerian navies. It is controlled by a set of binoculars atop a single manually operated pedestal director.

Because of its low speed and short range, Sea Cat cannot engage supersonic targets. Development of a proposed Sea Cat 2 was dropped in favor of Sea Wolf; the much greater sophistication of the latter system testifies to the complexity of the supersonic sea-skimming-missile problem.

◆ Sea Dart (GWS 30; CF 299)

Dimensions: 16.5 × 172 in, including booster; span 36 in
Weight: 1200 lb **Warhead:** 50-lb HE/continuous rod
Propulsion: ramjet with rocket boost **Speed:** Mach 2.5–3.0
Range: 25–30 nm (altitude 100–60,000 ft)

Sea Dart is the standard British area-defense missile, a semi-actively homing ramjet. Like the defunct U.S. Talos, Sea Dart uses 4 interferometer aeriels (polyrods) for guidance, rather than a dish. They provide monopulse tracking; the missile has a reference antenna pointing back and flies a proportional-navigation path. Guidance is provided by 2 Type 909 tracker-illuminators. This radar is cued by a Type 992Q high-definition (target-indication) radar, which in turn is cued by a Type 965 or Type 1022 broad-beam search radar; only the illuminator searches in elevation.

Because it employs vacuum-tube technology, this system is reportedly not entirely reliable. A Sea Dart 2 program, announced in November 1977, reportedly amounted to a British equivalent of the U.S. 3-T "Get-Well" program of the 1960s. However, Mark 2 would also have had thrust-vector control (and a more powerful booster), new wings and fins to allow the missile to engage higher-altitude targets, more fuel tankage, and a higher proportion of solid-state circuits. Presumably solid-state circuitry would also have applied to the guidance radars, which had the most serious reliability problems. Moreover, using the separate search and target-indication radars in combination increased the system's response time. Marconi proposed, then, to replace the obsolescent 965/992 combination with a single search/target-indication radar, STIR. Sea Dart 2 would also have had a programmable autopilot (as in the U.S. NTU). This major upgrade was reportedly ordered after the system failed against a simulated saturation attack off Australia. By 1980 the Sea Dart 2 program had been reduced to ECCM improvements, including the new radars. However, the program (including the new Type 909M and STIR radars) was killed in 1981 as part of the Nott Defense Review. This program seems to have been revived following the Falklands War, without the

A Sea Dart launcher (Mk 30) on board the missile destroyer HMS Glasgow, 1990. In contrast to U.S. vertically loaded launchers, the blast doors project well above the ship's deck. (Author)

Mk 2 designation. Modernization will include replacement of existing Type 992Q radars with the new Type 996 for better targeting.

A new blast warhead (GMk 39A1) was delivered beginning in 1987. Presumably this warhead is a response to the problem of intercepting fast passing targets.

Missiles are loaded in 2 stages. Stowed vertically in a magazine below the water line, missiles are then carried up (by chain hoist) into an intermediate position, warmed up (for 30–60 sec), hoisted into an upper-deck position, and only then rammed hydraulically onto the launcher: this process is analogous to the 2-stage hoists used by many heavy naval guns. This practice should increase safety (the Royal Navy has been extremely con-

scious of safety requirements for magazines since World War I) but may also reduce the rate of fire. Reportedly, at least 1 Sea Dart ship found in the Falklands War that her blast or flash (outer hoist) doors did not close properly at times. Typically 2 missiles are held in readiness below the launcher, with another 2 in the intermediate position. The intermediate position is probably required to fit the booster, just as in Terrier/SM-1 and Masurca. The cumbersome magazine arrangement may explain proposals for box-launched Sea Dart. However, reportedly HMS *Invincible* was able to fire 6 Sea Darts in 2 min on 1 occasion, or 1 salvo (2 missiles) every 40 sec. HMS *Bristol* is equipped with a heavy Mk 30 (i.e., GWS 30) Mod 0 electrically driven launcher, whereas later ships have the lighter-weight Mod 1. Missile capacity: HMS *Bristol*, 22 missiles; Type 42 (all versions), 22 missiles; *Invincible* class, 36 missiles. The 22-missile figure is often rendered 20, and the difference may be test missiles.

Development began in August 1962, with full development approved in May 1963, tests in 1965, and production announced in November 1967. The 500th missile was fired by HMS *Bristol* in November 1986. Using Sea Dart, HMS *Invincible* shot down a Petrel target drone on the Hebrides missile range in November 1985.

Argentina was the only export customer, for its 2 Type 42 destroyers. As of 1986 estimated production was 1600 (plus 60 for Argentina), and estimated unit price was \$300,000. A new production contract, reportedly for 100 missiles with the new warhead, was let in August 1986.

Sea Dart was the major British naval area-defense missile used in the Falklands War and is credited with having shot down 7 Argentine aircraft. Unfortunately several other firing opportunities were lost because of the system's unreliability, e.g., because magazine doors did not always allow missiles to be loaded promptly. The system was also degraded by its surveillance and acquisition radars, which reportedly lacked the MTI required to detect and track Argentine aircraft popping up over the nearby shore.

A box-launched Lightweight Sea Dart system was announced in 1978, using the Marconi ST805 tracker-illuminator (ranges are reportedly 60 km on an airplane and 14 km on a missile, the former increasing to 80 km with a larger dish). The missile has also been promoted as a surface-to-surface weapon with a range of 25–30 km, climbing steeply after launch, then diving at 30 deg to build up momentum for deep penetration of a target. Thus far none has been sold. A land-based version, Guardian, for defense of the Falklands, was offered in September 1982 but was not purchased.

◆ Sea Slug (GWS 1)

Dimensions: 16.1 in × 20 ft (19 ft 8 in for Mk 1); span 56.6 in

Weight: approx 4400 lb total (1980 lb without boosters)

Warhead: approx 200 lb

Propulsion: strap-on boosters with sustainer rocket

Speed: Mach 1.8 **Range:** Reported range for Mk 2 is 24.3 nm.

Sea Slug is obsolete; it is the survivor of the initial postwar generation of Western command-guided (beam-riding) surface-to-air naval missiles. The U.S. equivalent, now extinct, was the beam-riding version of Terrier. The original requirement, defining Sea Slug Mk 1, was that the missile be able to engage a high-

Sea Dart. (Sea Power)

HMS *Devonshire* fires a Sea Slug. The cylindrical radar just forward of the helicopter platform is Type 901; forward of the after funnel are the Type 278 height-finder and the Type 965 (AKE-1 antenna) search radar. (U.S. Naval Institute)

altitude 650-k bomber at 30,000 yd (15 nm), i.e., at about 50% greater range than the contemporary U.S. Terrier. Sea Slug Mk 1 development trials were completed in 1961.

Sea Slug Mk 2 was intended to achieve 20% better performance than Mk 1, to be much more lethal against low-flying aircraft, and to have an operating range of 70,000 yd and a maximum altitude of 65,000 ft. It also had new design features for antiship use. To achieve this performance, it had more powerful Gosling boosters and a more powerful Deerhound sustainer. There were alternative warheads, although the standard was still a continuous-rod antiaircraft type. It had 3 independent fuze systems: an IR proximity fuze, an impact fuze (for antiship effect), and provision for command detonation.

The Sea Slug guidance radar (Type 901) produces 3 beams: a gathering beam, a target-tracking beam, and a separate missile-guidance beam. The last makes possible up-and-over attacks against low-flying aircraft (the guidance beam is elevated, and the missile commanded to dive) and against surface targets (at ranges of up to 40,000 yd). This type of guidance was somewhat similar to that adopted for the U.S. Talos, except that terminal guidance was by command rather than by semiactive homing. The missile, therefore, could not follow violently maneuvering targets, and its accuracy declined with range. These limitations were acceptable for a weapon designed, like the contemporary U.S. Terrier, to deal with large subsonic bombers (Sea Slug was originally made large enough to accommodate a homing antenna, but none was ever made for it). The lack of terminal homing became crippling as targets became more agile. Thus, although 2 ships, the *Antrim* and *Glamorgan*, carried Sea Slug into the Falklands War, the missile was not used for fleet air defense. HMS *Glamorgan* did fire hers against Port Stanley airport.

Work on Mk 2 began about 1957, and tests were completed in 1965. However, in fleet firings the missile tended to break up when its boosters blew away (they separated 1 by 1 as they burned out, and subjected the missile to heavy but unbalanced loads). The problem seems to have been solved in 1971–72.

This missile was carried only by British "County"-class destroyers. Except for the disarmed accommodation ship HMS *Kent*, the only surviving units have been sold to Chile and Pakistan. The Chileans elected to retain Sea Slug in 2 of their 4 ships; in 1986 they bought the remaining spare parts and spare missiles.

Sea Slug is unique in having its 4 strap-on boosters attached around its nose rather than its tail. The wings and control surfaces are attached at 45-deg angles. The missile was designed to be stowed horizontally, rather than vertically (as in the first U.S. Terrier launchers); and in "County"-class destroyers the centerline magazine takes up much of the total length of the ship, resembling the hangar of a small carrier. Capacity is 39 missiles. The earliest County-class ships stowed all their missiles ready for service (i.e., finned) on 2 parallel tracks for a total capacity of 28. Later ships, however, carried about 18 ready-service rounds, with about 20 more forward requiring winging and finning before they could be fired (there was a winging/finning compartment forward of the launcher). Because the wingless missiles were much narrower, they could be stowed more densely.

◆ Sea Wolf (GWS 25, 26)

Dimensions: 18 cm × 2 m; span 56 cm [7.1 × 75 × 22 in]
Weight: 82 kg [180 lb] **Warhead:** approx 14 kg [31 lb]
Propulsion: boost-glide; burn time 2–3 sec
Speed: Mach 2 **Range:** approx 5 km [5500 yd]

Sea Wolf is a point-defense missile, normally carried in a 6-round trainable launcher. Guidance is by command to line of sight, using either a radar or a television tracker. The missile is gathered into the tracking beam and command-guided up the beam until intercepting the target. A ship carries 1 radar per missile launcher, so that (for example) a Type 22 frigate has 2 engagement channels. The tracker operates in I-band, the command link in J-band; individual trackers operate in different

Vertically launched Sea Wolf. (Author)

frequencies, so that a ship can guide 2 missiles independently toward the same (or alternative) targets simultaneously. Missile launch is entirely automatic (subject to operator veto), the weapons system ranking and engaging threats in turn. During the Falklands War, this system (on board Type 22 frigates) was used for the close-in defense of the British aircraft carriers. It was discovered that the automatic threat-ranker tended not to deal with crossing targets, and new software had to be provided on the spot. This experience shows both the inherent flexibility of software-based digital systems, and also the effect of the assumptions (in this case, that the system was purely for self-defense) written into that software.

Targets are acquired and tracked by back-to-back Type 967/968 radars, and the associated guidance radar is Type 910. The search/track radars are 2D, the target being located in elevation by the Type 910 tracker itself.

A lightweight version (GWS 25 Mod 2) is being developed for the *Invincible*-class carriers and Type 42 Batch III destroyers, using a 4-barrel launcher and a lightweight tracker (Type 911, the Marconi 805SW); the contract award was announced 1 February 1988. The Type 911 tracker had already been tested on board HMS *Brave*, in November 1986. All subsequent Type 22s are so fitted. This system is GWS 25 Mod 3. Besides Type 911, Mod 3 employs upgraded Type 967/968 radars. The lightweight Mod 2 system uses a launcher based on that developed for Sea Cat; Mod 2 fires containerized missiles. Total weight is 2.5 tonnes, compared to 7.5 tonnes for the earlier 6-barrel launcher. Each containerized missile weighs 170 kg.

A vertical-launch system (GWS 26) is being developed for the new Type 23 ("Duke"-class) frigates, a Sea Wolf with a booster already having been launched from an obsolete frigate (September 1982). It appears that British Aerospace was interested in vertical launch at a much earlier date, since 7 Sea Wolf-type

Sea Wolf being loaded. (British Ministry of Defence)

missiles were launched and turned over to normal flight mode in 1978 in Project SINNER. The first British official development contract was let in the fall of 1983. Vertical-launch Sea Wolf installations will use a new Type 911(2) tracking radar, an improved version of the Type 911(1) now being installed. In the vertical-launching system, the missile itself is provided with a long, finned booster with thrust-vector control. The booster reportedly adds about 50% to the range of the missile, for a maximum of about 8 km.

A development contract for a more sophisticated version of the system, GWS 27, was let in 1986. It was later canceled. GWS 27 would have used an active seeker and a phased-array tracker, the Marconi S1805SW Multifire. Reportedly, 1 goal of the GWS 27 program was to more than double the range of the missile, to beyond 10 km. Missiles would have been command-guided into a terminal homing basket, or else fired with pre-programmed inertial mid-course guidance autopilots. The Marconi seeker intended for GWS 27 was displayed at RNEE 1985.

British Aerospace has also marketed a lightweight Sea Wolf using the Signaal VM40 tracking radar.

Sea Wolf was initially conceived as a faster follow-on to Sea Cat, to engage supersonic targets. In June 1967 a contract for what was then designated PX430 (CONFESSOR) was let to British Aircraft Corporation. The initial production contract followed in July 1968, and the first missile was fired in 1973. A Sea Wolf hit a Mach-2 Petrel target in 1974 and a 4.5-in shell in June 1977. This missile proved quite successful during the Falklands War. On 1 occasion, 4 Argentine aircraft attacked a frigate. Two were shot down, and a third crashed trying to evade a Sea Wolf. Only the fourth escaped. In all, Sea Wolf was credited with having shot down 5 aircraft during the war.

This system was ordered by Kuwait, but in March 1988 the British Ministry of Defence blocked the sale on the grounds that the technology involved might be transferred further.

In 1988 British Aerospace offered a modified vertical-launch Sea Wolf, named Wolverine, as a near-term land-based anti-tactical-ballistic-missile weapon. The initial Wolverine proposal was a boosted missile with an elongated nose carrying flechettes and an active radar seeker, which was derived from the seeker originally proposed for an active version of the Sky Flash air-to-air missile. With the disappearance of the Soviet SS-20 (because of the INF Treaty), the remaining threat was considerably less demanding, and BAe was able to discard active guidance. The current proposal employs MRCLOS (Missile Ref-

erence Command to Line of Sight). MRCLOS uses an inertial reference unit in the missile, reducing the number of updates required by a pure command to line of sight (CLOS) system. That reduction, in turn, permits a single fire-control unit to guide several missiles on a time-shared basis. BAe currently claims that MRCLOS would suffice against weapons such as the upgraded Soviet SS-23 and SCUD B, although an active missile seeker will still be needed to deal with future weapons. Presumably MRCLOS would have a potential naval application.

In mid-1989 the British MoD funded a BAe/Marconi Sea Wolf mid-life update, Marconi concentrating on the radar. Tenders for competitive project definition were to be issued in 1990, for completion in 1992. An initial production contract may be issued in 1993.

The first Sea Wolf VLS missile was handed over to the Royal Navy in 1989.

◆ SDMS

Support Defence Missile System would be used by a missile ship to defend the adjacent 2 or 3 ships, as the Type 22 frigates defended carriers in the Falklands. It is conceived as the successor to current area-defense missiles (Sea Dart) and will presumably arm the next-generation air-defense destroyer (the Type 42 successor to be purchased in place of the NATO frigate). ARE accepted much shorter range in view of the rise of sea-skimmers that approach at short range only, making classical area air defense impossible. The project, therefore, stresses fast reaction and high rate of fire. SDMS will almost certainly be the FAMS missile, but in 1990 there were reports that the existing ASTER did not meet British requirements. Prior to British acceptance of FAMS, a likely candidate had been GWS 27, Sea Wolf with an active seeker and with command mid-course guidance.

SDMS is 1 of 3 parallel ARE programs for next-generation air defense; the others are VSRAD and the active decoy.

◆ VSRAD-2000

Very Short Range Air Defence is an ARE-sponsored program parallel to SDMS. It is conceived as a last-ditch point defense, a short-range hypervelocity weapon that can be accommodated on board merchant ships (STUFT), but that can also be connected into a ship's central command/control system. ARE prefers a missile to a gun because it doubts whether a gun can destroy the incoming missile at sufficient range, and also because it doubts the ability of GFCs to deal with future maneuvering targets. Several alternatives are under consideration, including the potential for international collaboration (see VSRAD in the international section). ARE has displayed 1 based on the Short Seastreak, as well as an alternative using a retractable 4-rnd firing ramp. Seastreak itself was developed as part of a VSRAD contract with MoD.

◆ Rascal CIWS

At the RNEE exhibition in the fall of 1987, Rascal displayed a mock-up of a new private-venture close-in weapons (missile) system the company is developing, for introduction about 1995. The system consists of a box launcher on a stabilized platform, with a noncleaving radome on top. The box (about 1.7 m wide, 1.8 m long, and 0.7 m high) carries 3 missiles on each side, stacked vertically, with electronics and hydraulics between and with windows for 2 optronic sensors in the front. The radome carries a K-band CW search radar, scanning at high speed, and covering an 80-deg arc in elevation. Presumably the radar detects targets by their doppler. Threats are automatically evaluated and passed to an M-band tracking radar using an array antenna (to form both a wide beam for missile gathering and a narrow beam for command to line of sight). Very fast missiles are to be used, so that even though engagement range will be short there will be time for at least 1 re-engagement should the first fail. Maximum delay from detection to interception will be 3 sec. Total system weight is to be no more than 1.5 metric tons. Reportedly the missile will be an adaptation of the British

The Racal CIWS mock-up, on display at RNEE 1987. (R. Cheung)

Aerospace Thunderbolt, the unsuccessful competitor with Starstreak for a British Army contract.

The Racal system is interesting because it suggests a movement away from current gun-based CIWS systems back toward missiles, which should have a high unit-kill probability, but which are often ineffective inside a substantial minimum range. Although the system was described as a private venture, the Racal proposal may reflect the requirements of VSRAAD 2000.

UNITED STATES

◆ Aegis

See radar integration under AAW radars above.

◆ RAM (RIM-116A)

Dimensions: 5 × 111 in; span 17.25 in **Weight:** 162 lb
Warhead: 5 lb **Propulsion:** solid-fuel rocket
Speed: Mach 2.0+ **Range:** 5 nm

The Rolling Airframe Missile (RAM) is a new point-defense weapon developed as a joint U.S. (General Dynamics)–West German (RAM GmbH)–Danish (Per Udsen) program.

Unlike Sea Sparrow, RAM is a fire-and-forget weapon, homing either on the infrared signature (forward-aspect glint) or the emissions of the homing radar of the incoming weapon. RAM uses a Sidewinder motor, warhead, and fuze, a Stinger infrared seeker, and a new 2-antenna RF seeker. The missile spins as it flies, so that 2 canard control fins (and 2 RF antennas) do the

RAM (RIM-116A) firing. (General Dynamics)

work that 4 of each do in a nonspinning missile. Four tail fins keep the missile spinning.

In theory, the missile is fired in response to radar (or passive electronic intercept or passive electro-optical) warning, launched on a selected bearing and elevation. RAM flies toward its target on the basis of RF mid-course guidance. The missile shifts to infrared terminal guidance but can continue on RF if weather conditions (e.g., too little sun to provide too little glint) provide too little IR signature. In theory, this fire-and-forget operation should make it possible for even a small combatant to deal with multiple attackers.

There are 3 alternative launchers: a standard 21-rnd EX-31 for patrol boats up to large amphibious ships (using the same base and turning mass as a Phalanx mount), a modified NATO Sea Sparrow launcher (2 cells occupied by a total of 10 RAMs), and a special RAM Alternate Launching System (RALS) carrying 10 rnds in 2 arms. RALS has been designed specifically for small craft, and it has been proposed to the Royal Danish Navy for installation on board Standard Flex-300 and *Niels Juel*-class ships.

Planned U.S. EX-31 installations: 2 LCC, 5 LHA, 7 LPH. The Sea Sparrow change will go into aircraft carriers, LHDs, AORs, and the *Spruance* class.

LAUNCHER CHARACTERISTICS

	Standard	RALS
Above-Decks	11,424 lb	7200 lb
Below-Decks	2,105 lb	
Working Circle	129 in	
Elevation	–25/+80 deg	–25/+85 deg
Capacity	21	10

RAM production was suspended because of test and cost problems, which have delayed the system about 5 yr in all. However, on 30 March 1987 U.S. Secretary of Defense Caspar Weinberger certified that the missile had passed its tests and would, therefore, enter production. At that time it was expected that the first 500 would cost \$145,000 (FY86) each, cost averaging \$100,000 for the remaining 4500 planned U.S. weapons. An MoU for U.S.-German production was signed in August 1987, at which time the United States planned to buy 30 launchers, and Germany planned 58 launchers (1923 missiles). The German producer will be RAM GmbH, and it and General Dynamics are to compete for up to 70% of the annual binational purchase.

The first 117 U.S. production missiles were authorized under FY86, FY88, 240; FY89, 260 (U.S. production only). The January 1989 U.S. budget request showed 580 RAMs in FY90 and 540 in FY91. The FY91 budget (January 1990) showed the figure for that year cut to 405, at a projected unit cost of \$174,000.

As of 1990, the Royal Danish Navy is considering buying RAM. Drawings of the new Japanese 1900-ton frigate show RAM; presumably, the Japanese plan to manufacture the missile under license.

RAM is limited in that some missiles, particularly divers, use IR or semiactive-radar rather than active-radar guidance and, hence, will not provide the necessary RF signature. The projected solution is a more sensitive IR seeker, for search as well as terminal homing. The new version is RAM II; a development contract was signed in December 1989.

The new IR seeker is to be sufficiently sensitive for the missile to acquire targets before launch, without any RF signature being present. The existing reticle (point) seeker is to be replaced by an image-scanning seeker (as in a FLIR), and the IR mode and search pattern will be selectable from the launcher. RAM II will retain the dual-mode guidance capability, and a missile launched in RF mode will default to IR search if RF acquisition is lost. This program was initially known as IRMU (IR Mode Upgrade), and it was demonstrated over water early in 1990. As of May 1990, the RAM II seeker had not yet been chosen.

There are several new launcher concepts. The U.S. program for modernizing protection of shipping (POS) ships, described in the ASW section, includes improved hard-kill self-defense, which means RAM missiles. This program affects *Spruance*-class destroyers and *Knox*- and *Perry*-class frigates. Funding, at least for the first 2 classes, is likely to begin during FY91. *Perry*-class frigates are to have their Mk 13 launchers modified so that they can load twin RAM canisters (on hardbacks) as single rounds, in place of single SM-1 missiles. NSWC/Dahlgren has proposed Sideshooter, in which RAM launchers are mounted on the outside of a 5-in Mk 45 gun mount. The mount can carry two 21-rnd, four 5-rnd, or two 5-rnd launchers.

General Dynamics has proposed using a ship GFCs to designate RAM targets. More generally, RAM can be integrated with a ship CDS through a computer-based self-defense module interface. The module should be effective with any ship CDS (presumably, it was developed as part of the larger integration effort now underway); using it, RAM should be able to exploit fire-control radar, Phalanx radar, ESM, or IR tracks. This idea was tested on board the destroyer *David R. Ray*, the ship's Phalanx detecting and acquiring the target. General Dynamics argues that Phalanx and RAM are complementary since RAM will generally kill targets at ranges that preclude debris from hitting the ship, while Phalanx can deal with leakers at its shorter range.

The FY89 program began work on RAM utilization of CIWS radar information and also on the IR seeker upgrade to deal with passive targets. The FY90 program began work on a Block I upgrade, including launcher modifications and system evaluation. The planned FY91 program includes design work on RAM launch from Mk 13 launchers.

As of mid-1990, plans to carry RAM missiles in modified Sea Sparrow launchers had been dropped because of cost and technical difficulties. That leaves the EX-31 launcher and probably a modified Mk 13. RALS, the Danish lightweight launcher, has been tested, but the missile has not yet been adopted by the Royal Danish Navy.

The RAM operational requirement was issued in May 1975, followed by an MoU with Germany for advanced development in 1977 (with Denmark in 1979) and by an MoU for full-scale engineering development in March 1979. RAM first flew in 1978.

See Sidewinder (U.S. air-to-air missile below).

◆ Sea Sparrow

See Sparrow (U.S. air-to-air missile below).

◆ Standard Missile-1 (Medium Range) (RIM-66A and -66B)

Dimensions: 13.5 × 176 in; span 42.5 in

Weight: 1240 lb (1390 lb for RIM-66B)

Warhead: 137-lb continuous rod

Propulsion: boost-sustain rocket **Speed:** Mach 1.25–3.5

Range: 35,000 yd, minimum 3000 yd for air targets; maximum intercept altitude 65,000 ft (maximum intercept range 50,000 yd, maximum altitude 80,000 ft for RIM-66B)

Data are for RIM-66A except as noted.

The Standard Missile replaced the earlier Tartar and Terrier, using as many parts in common as possible for, respectively, the medium-range (MR) weapon with a boost-sustain motor and the extended-range (ER) weapon with a separate booster and sustainer. The design was adapted from that of the TRIP (Tartar Reliability Improvement Program) weapon, which had also been specified for the abortive Typhon program. Reliability improvements included all-electric design (hydraulic power for control surfaces was eliminated) and solid-state electronics with the first battery power in a U.S. missile (which drastically reduced warm-up time, from 26 sec to 1/15 sec). Those improvements in turn eliminated the requirement for shipboard check-out, missiles being shipped as "wooden rounds" good for a 3-yr no-test cycle. The Standard Missile also incorporated a single-

A twin Standard Missile launcher on board a Taiwanese WJ-III (modified FRAM *Gearing*) destroyer. This type is unique to the Taiwanese navy. (F. S. Mei)

sideband receiver (for improved ECCM and clutter rejection) and "doppler offset" to improve discrimination among multiple targets. An increase from 12 to 19 guidance channels reduced ship-to-ship interference. While RIM-66A was an interim weapon that used the existing Mk 27 Tartar motor, RIM-66B introduced a new Mk 56 dual-thrust rocket motor, to achieve 45% greater intercept range, 33% greater peak velocity, 25% greater intercept altitude, and greater terminal maneuverability. RIM-66C is SM-2(MR) (see below).

Standard Missile (Medium Range) being fired from a Mk 26 launcher. The SM-1, SM-2, and Tartar missiles are virtually identical in appearance, though quite different in capability. (U.S. Navy)

Improvements in the Standard Missiles' intercept envelopes resulted from the change from semiactive to command guidance. (General Dynamics)

The original design requirements for the SM-1(MR) missile were a maximum range of 25 nm and a maximum intercept altitude of 80,000 ft. By 1971, however, an (MR) missile at White Sands had successfully intercepted an augmented target at a range of 38 nm. That was without using the energy-efficient trajectory of the SM-2 missile system; at the time it was estimated that SM-2(MR) would be able to engage targets at a range of 40 nm, using the original SM-1 motor and airframe. Longer range meant a lengthier flight, and the electric battery had sufficient energy for 200 sec of operation.

Standard differed from its Terrier/Tartar predecessors in using an adaptive autopilot, i.e., an autopilot that could adapt to changes in missile velocity (e.g., after burnout) and atmospheric pressure (e.g., as it climbed into thinner air). The missile continuously measured its own aerodynamics by sensing the strength of an intentionally induced roll oscillation. In 1971 it was claimed that the existing autopilot could deal with altitudes from sea level up to 100,000 ft, with payload variations of up to 1000 lb (i.e., with a fully burnt-out motor), and with speeds as great as Mach 5.

The original 1964 design allocated space and weight for an RF up/down link for mid-course guidance and also for the inertial reference system for the autopilot, which it needed to exploit the link. Both capabilities were used in the SM-2 version of the missile.

From FY72 on, missiles were bought with a new proximity fuze, TDD (target detecting device) Mk 45. By this time targets were so varied that conventional proximity fuzes no longer sufficed. They formed a cone-shaped sensing pattern whose length equaled the range cutoff. The warhead exploded a fixed time after a target penetrated the outer edge of the cone. The time

delay and the range cutoff were related to the size of the target: if the delay was too long, for example, the blast of the warhead might pass beyond an approaching small target. Until about 1970 it was possible to choose a compromise fuze design (cone angle, range cutoff, and time delay) that could hit roughly amidships on large targets without missing small ones. That was impossible when targets, such as antiship missiles, became very small (particularly when, if they were crossing targets, the fuze would approach broadside-on, seeing their body diameters as their effective lengths). The solution was to use a pair of beams that, in effect, measured target length and permitted the fuze to adjust the time delay to match. Mk 45 was also specially adapted to low-altitude conditions (it could, therefore, trigger overhead bursts against surface targets), and it incorporated new ECCM features. Advanced development work began in FY65, and it was completed at the end of FY69. Engineering development began late in 1969, and Mk 45 was first delivered to the fleet in 1973.

Other weapons in the series were designed for specific anti-surface applications: RGM-66D was Standard ARM (ship-to-ship, homing on the target's radar emissions); RGM-66E was a Standard ARM adapted for firing from an ASROC launcher; RGM-66F was a Standard Active antiship missile. AGM-78, Standard ARM (see Strike/Surface Warfare section), is an air-launched antiradar version, now being replaced by HARM, AGM-88A (see Strike/Surface Warfare section). In the surface-to-surface mode, Standard ARM follows an up-and-over trajectory and thus achieves a range of 35–40 nm (minimum range 7000 yd) carrying a 219-lb warhead (102-lb high explosive). Standard ARM (shipborne) was fitted to 2 U.S. patrol gunboats; it is carried by the Korean *Paek Ku 51* (ex-USS *Benicia*) and *Paek Ku 52–55* of the PSMM-5 class. Standard was fitted to the Iranian destroyers *Babr* and *Palang*, in box launchers (4 per ship, with 4 reloads) as a surface-to-air missile, not Standard ARM (and so is limited to horizon range for surface-to-surface fire). It seems likely that the Standard installation on board the third Iranian destroyer, *Damavand*, is for antiship use only, given the nature of her FCS (Sea Hunter 4). The interim surface-to-surface missile (ISSM) program was initiated in FY70, and the first of 5 *Knox*-class frigates fired Standard semiactive missiles in February 1972 (the *Trippe*). She used 2 of her 8 ASROC cells for antiship missiles. ISSM was replaced by Harpoon in U.S. service.

The West German navy reportedly bought Standard (at that time, Tartar) for German missile destroyers because the weapon promised a useful surface-to-surface capability. For a time General Dynamics was developing a version of the missile armed with a Bullpup warhead, specifically for the antiship role, to be carried on board German fast attack craft. This weapon was tested, but the Germans chose Exocet instead.

Development of the Standard Missile began in FY63, with tests in FY65–67, and procurement from FY67 onward. Procurement of SM-1(MR) ended in FY85 (700 in FY84, 600 in FY85). Consequently, in the future ships firing off their SM-1 missiles will have to use SM-2(MR) with its programmable autopilot disabled; that use should lengthen the SM-2's production run and cut that missile's unit cost. Total SM-1(MR) production was reportedly 12,000. The Standard Missile concept, unifying the design of the Tartar and Terrier follow-ons, was proposed in October 1963 by the Surface Missile Systems Project Office, and development was approved by the secretary of the navy on 10 April 1964. Because of the standardization of both (ER) and (MR) versions, unit cost was well below that of the earlier Tartar and Terrier until the introduction of the more complex fore-and-aft fuze (TDD Mk 45) in FY72 missiles.

Developments of the basic RIM-66B are incremental and are denoted by block changes. The current version is Block VI; the first production version was Block II. Versions were

Block III First 1194 production units.

Block IV Next 1665 production units. Upgrades included ECCM improvements, reduced minimum range, and shorter acquisi-

tion time against surface and crossing targets. Block III missiles were upgraded to Block IV standard from about 1970 on.

Block V Next 2141 production units. This program began in mid-1967 to achieve substantially better maneuverability and improved ECCM. These missiles were better able to engage surface targets because they reduced the effect of glint (target scintillation) by using a modified scanning system (sequential plane scan, SPS, rather than conical scan). The new integrated-circuit autopilot reacted more quickly, and the seeker head was driven directly rather than through gearing.

Block VI The current units add the SM-2 monopulse seeker, for better resistance to countermeasures, and a new proximity fuze (target detection device [TDD] Mk 45 Mod 4), but the guidance section is interchangeable with that of Block V. Both Block VI and SM-2(MR) Block II are 10 in longer than earlier versions to accommodate the new Mk 56 motor described above. Block VI also has a new dual-initiated warhead for greater fragment velocity and density to deal with targets closing at higher speed. Acceptance trials were completed in March 1983, and Block VI began to replace Block V in procurement in FY80.

The termination of SM-1 production has had 2 important consequences. First, to the extent that the current effort at battle-group AAW coordination is successful, SM-1 ships carrying SM-2 missiles can act as spare magazines for Aegis ships, contributing to the overall firepower of the battle group. Second, since the United States is not yet willing to export SM-2 technology, it is unable to provide further missiles to those NATO allies currently operating SM-1. The U.S. decision reportedly contributed, in part, to the French choice not to build the planned second group of SM-1-armed missile destroyers (*Casard* class).

For details of the predecessor Tartar (RIM-24) missile, probably now extinct, see the previous edition of this book.

◆ Standard Missile-1 (Extended Range) (RIM-67A)

Dimensions: 13.5 × 160.182 in (wing span 24 in, fin span 42.48 in) plus booster (18 × 156.6 in, with 62.25-in fins)

Weight: 1148.27 lb plus 1876.7-lb booster (2969 lb total for RIM-67B)

Warhead: approx 250 lb

Propulsion: sustainer rocket with separate booster

Speed: Mach 3.0

Range: 40 nm (minimum 7000 yd, altitude limits 50–80,000 ft)

This successor to Terrier (RIM-2) incorporates many components in common with RIM-66 SM-1(MR), but with a different rocket motor capable of greater range. Procurement of the SM-1 Block II (ER) version ended after 1983 (1095 ordered FY82, 375 FY83). Compared to Block I, Block II has a more energetic motor

DIFFERENCES FROM AA MODE

3. DISABLES THE PROXIMITY FUZE

Standard Missiles' flight paths.

(for higher intercept altitude), a more lethal warhead, and better resistance to countermeasures.

The original design of the SM-1(ER) missile called for a range of 40 nm and a maximum altitude of 80,000 ft. However, by 1971 a missile fired at White Sands had intercepted an augmented target at 70 nm. At that time it was estimated that SM-2(ER)'s range (using the original motor and airframe) would be 90 nm.

The nuclear version of Terrier, the only version of the predecessor to SM-1(ER) remaining in service, has now been retired. See the previous edition of this book for details of this weapon.

◆ Standard Missile-2 (RIM-66C and RIM-67B)

SM-2 adds a programmable autopilot to the basic SM-1 missile, so that SM-2 can be command-guided into a homing "basket" near the projected position of the target. SM-2 was the first tactical missile to incorporate inertial navigation, to guide the missile from the launching ship up into the designated homing "basket." Semiactive illumination is needed only toward the end of the missile's flight. SM-2 is the basis of the Aegis system, which counters saturation by time-sharing illuminators. SM-2, in both (MR) and (ER) versions, is also part of the New Threat Upgrade (NTU) to existing missile systems. NTU ships do not enjoy the tracking precision of the SPY-1 phased-array radar, so illumination must be provided for a longer period, but even so they can engage more targets per unit time.

Like SM-1, SM-2 exists in 2 versions: a single-stage Medium Range (MR) weapon (RIM-66C), and a 2-stage Extended Range (ER) version (RIM-67B). Both share the same programmable autopilot. Aegis ships fire only the (MR) version because their rapid-fire launchers cannot accommodate the manual finning required by the (ER) weapon. The big boosters of these missiles require large fins; the smaller tail fins of the (MR) missiles fold during stowage. Missile cruisers with Mk 10 launchers can fire the (ER) version after undergoing NTU modernization.

The addition of command guidance increases a missile's range

SM-1(ER) being launched. (U.S. Naval Institute)

in 2 ways. A conventional semiactive missile homes all the way to its target: the illuminator must, therefore, provide enough energy for a sufficient amount to be reflected all the way back to the missile on its launcher. In contrast, a command-guided SM-2 requires illumination only near its target. The illuminator must still provide sufficient energy to reach 1 way, but only a fraction of the way back. The combination of command and semiactive is preferable to pure command because tracking (both of missile and of target) is unlikely to be precise enough to bring the missile within lethal range at many tens of miles, while the target maneuvers violently.

The missile also gains range because it can fly a more energy-efficient path than the direct chase of a semiactive weapon. When SM-2 replaced SM-1 (without any change in rocket motor), effective range approximately doubled (the stated improvement in the (MR) version was 60%). SM-1(MR)'s range was probably about 25 nm, so this improvement probably brought the range of SM-2(MR) to about 40 nm. In the case of SM-2(ER), the improvement was 50% or more. Altitude performance also improved. Published diagrams of SM-2(ER) Block I/II's range suggest a maximum range of 90 or even 100 nm. Maximum missile range against a given target is ultimately determined by terminal energy, as the missile glides after its sustainer engine burns out.

SM-2 Block I introduced a monopulse seeker, which counters self-screening jamming.

SM-2 Block II had an improved rocket motor, to deal with faster and more maneuverable targets. This motor doubled the effective range of the (MR) missile, probably bringing it up to the limit imposed by illuminator power. The (ER) Block II missile could fly much farther (i.e., enjoyed a much greater kinematic range), but its effective (illuminator-limited) range is presumably about the same as that of (MR) Block II (which in turn is about the same as that of (ER) Block I). In this case the advantage of the new motor was increased maneuverability against more difficult targets.

Block II also adds digital signal processing and a high-velocity fragmentation warhead (to kill targets passing at very high speeds). Block II was developed in response to a 1975 directive by the secretary of defense, who called for a faster, i.e., more energetic, weapon (in both (MR) and (ER) versions). In March 1981 an SM-2 with the new Mk 70 booster set an altitude record for the interception of a drone.

Missiles procured from FY88 on are Block III, with an improved low-altitude fuze. Development of another new motor, the dual-thrust Mk 104, was announced in the FY86 budget. Mk 104 is presumably intended for an SM-2(MR) Block V, an unboosted equivalent to Block IV.

SM-2(ER) required a data link back to the launching ship. The link was first tested on board the destroyer *Mahan* in FY79, and installation of the link is associated with the NTU program (see the entry under shipboard AAW radars above).

SM-2 Block I procurement ended in FY83. Block II (ER) was approved for service use in May 1983, and the (MR) version in December 1983. Block III, which incorporated low-altitude improvements developed under a 1984 Standard Missile Improvement Program, entered production in 1988 in both (MR) and (ER) versions. A new warhead and further fuze enhancements will be introduced in Block IIIA. As of early 1990, a "dramatically advanced guidance system" is to be retrofitted into missiles during FY91 as Block IIIB, and all-up Block IIIB missiles are to enter production in FY92.

In December 1985 it was estimated that 13,560 SM-2 missiles would be required; another estimate shows 8119 (MR) and 7270 (ER) missiles. The difference may reflect estimates of test and practice firing. Unit costs, as of FY82, were \$513,333 for (MR), \$572,333 for (ER). Total Standard Missile procurement (all versions): FY84, 1190; FY85, 1380; FY86, 1316. SM-2(MR) procurement began with 30 in FY80; then FY83, 150; FY86, 846; FY87, 844; FY88, 1310; FY89, 1310; as of January 1989 the U.S. budget request was 590 for FY90 and 900 in FY91. SM-2(ER): FY80, 55; FY86, 470; FY87, 350; none in FY88 or FY89.

The FY91 budget request (January 1990) included 600 SM-2 Block IIIA missiles. The FY90 budget had included 940 (i.e., more than had been requested), at a unit price of \$415,000.

A Missile Homing Improvement Program (MHIP) is to begin in FY91, for both Standard and Sparrow.

The Navy's proposal for a nuclear version, denoted SM-2(N), using a W81 warhead, was rejected in the FY80 budget but reinstated in FY81 (for procurement of test rounds). However, (N) was deleted from the FY86 budget by the congressional conference committee in favor of a nonnuclear solution. The chief argument in favor of SM-2(N) was the threat of steeply diving nuclear-armed air-to-surface missiles such as the Soviet AS-4/6. If a weapon could intercept such a missile only as it dove, a conventional weapon might tear off wings without destroying an armored nuclear bomb; and the Soviet weapon, tumbling, might still destroy its target by a near miss. The nonnuclear alternative was presumably a higher-energy missile (Block II or even Block IV), which could attack the incoming weapon farther out, before it began to dive, and bring it down outside any damaging range.

◆ SM-2 Aegis (ER) (SM-2 Block IV)

Dimensions: 13.5 × 256 in (booster: 21 × 72 in)
Weight: 3076 lb (total)

An SM-2 Block IV (Aegis ER) missile, with its short finless booster. (Raytheon)

SM-2 Aegis (ER) is a boosted version of SM-2(MR) designed specifically for Aegis ships equipped with Mk 26 or Mk 41 launchers, to deal with very fast or very high altitude targets. Added energy should make the weapon more agile, particularly at the edges of its flight envelope. The missile should also achieve greater range. Aegis ships could not use the regular SM-2(ER) configuration because their launchers are automatic (for high rates of fire) and, therefore, cannot accommodate the manual finning of the usual Mk 10 (SM-2(ER)) system. In 1987 the contract for SM-2 Block IV development was given to Raytheon; General Dynamics Pomona had been responsible for all SM-1/2 development up to that time.

Block IV is designed specifically for vertical launching, so the new missile's short (finless) booster uses thrust-vector control. Modifications to the missile itself include a slip-cast silica radome, a modified antenna with a new signal processor, an improved autopilot, and modified dorsal and tail fins (the latter with new actuators and a new clamp). Raytheon claims that the new aerodynamic surfaces will give considerable improvements in lift and control.

The FY91 budget request included the first 300 production SM-2 Block IV missiles.

◆ Sea Chapparral

See the entry for the Sidewinder air-to-air missile.

◆ Sea Sparrow

See the entry for the Sparrow air-to-air missile.

◆ Stinger (FIM-92)/FIF-2

Dimensions: 2.75 × 60 in **Weight:** 34.5 lb
Warhead: 6.6 lb (proximity fuze) **Propulsion:** 2-pulse rocket
Speed: Mach 2.0 **Range:** about 5500 yd

This surface-to-air missile was intended for use on land (e.g., by the marines), but since 1984 Stinger has been issued to many

A Stinger is fired from shipboard. Note the supporting ring. (General Dynamics)

U.S. warships and auxiliaries for point defense, particularly in Middle Eastern waters. For example, movies of the missile cruiser USS *Vincennes* showed a Stinger operator on deck. Target acquisition was initially entirely visual (via head phones), but the navy is now buying UPS-3 battlefield radars for this purpose. Compared to other hand-held infrared missiles, Stinger is said to have a greater capacity to home on the forward aspect of an incoming target. SA-7, for example, seems to be more limited to tail-aspect attacks and is more likely to be vulnerable to relatively simple infrared countermeasures.

Special features include a dual-color (IR and ultraviolet) seeker (for resistance to countermeasures) and a rosette-scan seeker (in Advanced Stinger) for target discrimination, e.g., between an airplane and a flare.

Recent procurements: FY84, 1205 navy; FY85, 2360 navy; FY86, 3439 navy; FY87, 536 navy; FY88, 425 navy, 3067 marines; FY89 request, none for navy, 3115 for marines. It was reported in April 1988 that purchases of Stinger by the navy had ended, with about 150 fewer than the 685 originally planned. Because it was designed for use on land, Stinger incorporated no shielding against the electromagnetic radiation typically present on shipboard. This problem is typical of land-warfare weapons placed on ships without special adaptation. In addition, the missile's launch blast could damage the ship's structure.

At the U.S. Navy League show in 1989, General Dynamics exhibited a shipboard firing platform for Stinger, a ring allowing the gunner to rest the launcher when not in use, with plastic poles to prevent firing in a direction that would damage the ship. The poles are analogous to the pipe rails fitted to many light antiaircraft guns during World War II, to keep their gunners from firing into their ships' superstructures. This is a problem for any manually controlled weapon since there is no automated FCS that incorporates the appropriate cut-offs.

This missile arms the new West German mine-countermeasures craft (Types 332 and 343), each of which has 2 Stinger positions (as well as 40-mm guns). The German designation for Stinger is Fliegerfaust 2 (FlF 2); Redeye was FlF 1.

Stinger was extremely successful in Afghanistan, against Soviet helicopters and ground-attack aircraft.

◆ ASAT

The antisatellite weapon is a new program begun in FY90, with a proposed budget of \$218.9 million for the first 2 years. The United States has had active antisatellite programs through the Reagan Administration, but in the past they have been an air force responsibility. The navy has argued that the satellites of most immediate tactical significance are relatively low flying Soviet naval reconnaissance craft, and that their prompt destruction may be essential in battle group operations. For example, destruction of a radar satellite just prior to launch can disrupt an Oscar's SS-N-19 missile attack by denying the submarine vital last-minute information. This tactical move is precisely analogous to destroying a Bear-D radar airplane to disrupt an SS-N-3 attack.

This type of attack is quite distinguishable from an attack on an early-warning (or, probably, signals intelligence) satellite in a higher orbit. It seems at least arguable that the Soviets cannot afford to place their tactical radar satellites in very high orbits, particularly if the U.S. Navy uses decoys and cross section-reduction techniques to make radar tracking of its ships more difficult. There will, then, generally be a very clear distinction between attacks on naval-related tactical satellites and attacks on satellites that might be considered more strategic in character. That distinction in turn should help differentiate naval ASAT, as a tactical operation, from strategic-warning ASAT, which some might consider destabilizing.

Reportedly, the decision to allow the navy to develop a sea-based ASAT reflects OSD agreement, late in 1988, that space should not be controlled by a single (i.e., air force) manager, but rather that at least some space defense tasks should be considered natural outgrowths of air defense at lower altitudes.

Reportedly, too, the navy's program is a response to rejection of the air force's ASAT program, which many in Congress considered strategically destabilizing. The air force's weapon was a miniature homing vehicle, carried aloft by an F-15 and then fired into orbit atop a rocket. The same weapon could be carried by an F-14; in each case, the fighter must fly a precisely defined high-energy trajectory, acting as the first stage of the interceptor rocket. A navy ASAT might also be fired out of a shipboard vertical launcher. As of the late spring of 1989, it appeared that tactical ASAT, which had been carried in budget documents as a joint army-navy program, would be developed by the army, presumably by ABMDA, the old Army Ballistic-Missile Defense Agency, at Huntsville, Alabama. The joint nature of the program would presumably be reflected in a requirement that the missile fit the standard navy vertical-launcher cell. Any possibility that the weapon would be carried aloft by a navy fighter thus seems to be ruled out. It may be that limitations on the size of the tactical ASAT missile will be reflected in inherent performance limitations sufficient to convince potential congressional critics that the weapon cannot be used against strategic warning satellites.

As Chief of Naval Operations, Admiral C. A. H. Trost chose the surface-ship VLS rather than the strategic-submarine missile tube as the preferred launcher. As of 1989, ASAT was planned as a kinetic-energy (direct-collision) weapon, with an undetermined sensor.

◆ Outer Air Battle Missile(s)

Since the 1970s the U.S. Navy has sought a longer-range, higher-energy replacement for the SM-2 series. Ideally, this replacement would be able to engage Soviet bombers before they could launch their antiship missiles, during what is now called the Outer Air Battle.

For a surface-launched weapon, the problem is twofold. First,

some means of guiding a missile, perhaps beyond the fleet's horizon, is needed. Second, the missile requires sustained high power. The second problem is more easily solved, since very long range hypersonic weapons already exist. In the 1970s it seems to have been assumed that the solution would be an integral rocket-ramjet, and the new Mk 26 launcher developed for Aegis ships was deliberately designed to fire future larger weapons with this type of propulsion. Because the current Vertical Launching System (Mk 41) is designed to accommodate Tomahawk cruise missiles, it can also accommodate a future long-range surface-to-air weapon.

Guidance is a much more serious problem. The most obvious solution is active homing rather than the semiactive homing of SM-2, but a small missile-borne active radar is unlikely to be able to overcome terminal countermeasures, as the targets will enjoy much greater power resources. It might be possible to use a combination of active radar and infrared "glint." One alternative is to limit the missile to a specific mission, the destruction of the escort jammers that generally accompany Soviet antiship air strikes. The missile could then home on the jamming emissions; the threat of the missile might force the Soviets to shut down their jammers, thus opening the platforms to shorter-range weapons. Another alternative is to use a platform closer to the target to provide guidance, a technique once called Forward Pass. One version is the Surface-Launched Air-Targeted (SLAT) missile, for which ships carry the heavy missiles and air platforms the relevant radars. In 1984 Martin Marietta proposed that OTH guidance be furnished by a dedicated radar satellite, but this idea was apparently too radical (and probably far too expensive).

Several extremely long range surface-to-air missiles were proposed through the 1970s, usually using rocket-ramjet power to achieve a combination of range and terminal maneuverability. The usual choices for guidance were concentration on Soviet escort jammers (home-on-jam) and Forward Pass (SLAT). LORAINÉ (see below) represents yet another, and quite different, alternative. A very long range home-on-jammer project, SOJS (Stand-Off Jammer Suppression), was canceled in 1981 with the announcement that, as important as this threat was, some new technical approach was needed.

At about this time there was also official reference to a ramjet-powered Long-Range Dual-Mission Missile (LRDMM), which could attack surface targets (at Mach 2.5) as well as very distant air targets (at Mach 4.5). As of 1978, the navy hoped that LRDMM could enter engineering development in April 1983. LRDMM would extend Aegis's range and might rely on E-2Cs for OTH engagement of targets such as Backfires and stand-off jammers. There was some interest, at the time, in commonality with the air force ASALM ramjet cruise missile, and some hope that the army would join in a triservice program. The ramjet missile Martin Marietta proposed for ASALM later surfaced as a possible Outer Air Battle alternative, and then became the SLAT supersonic target (and a Harpoon follow-on candidate—see Harpoon II in the Strike/Surface Warfare section).

Another project of the late 1970s was Thor, an abortive Martin Marietta project using a Sprint (ABM)-like very high acceleration missile. The Thor concept seems to have been applied both to very long and to very short range projects of this type, since the very high acceleration could boost a weapon to considerable range, or allow the missile to engage short-range targets that were maneuvering very violently.

A series of Outer Air Battle studies was carried out in the early 1980s, the objective being a pair of missiles, one for surface ships (to replace SM-2) and one for aircraft (to replace Phoenix). Ideally, both would use many of the same components.

A unitary Outer Air Battle Missile program began under the FY81 program, under the designation SM-3. Research efforts included improvements in IR guidance to supplement semiactive homing; more maneuverable aerodynamic design; the development of a linear autopilot (superior for high altitudes); and a directional, aimable warhead (for greater lethal radius and better effect against hardened targets). The Outer Air Battle study,

which was completed on 15 June 1983, set development milestones (a breadboard design in FY84, with wind tunnel tests and design review, followed by an FY85 concept definition competition). An RFP issued on 4 February 1985 included such guidance concepts as Forward Pass (see above) and called for commonality between the advanced air-to-air missile (AAAM) and the surface-to-air missile (ASAM). Reportedly ASAM was conceived as an 800-nm, Mach-4.5 ramjet.

Concept contracts were awarded on 31 May 1985 to Hughes, Martin Marietta, McDonnell Douglas, and Raytheon; study contracts were also awarded to General Dynamics and Grumman. Submissions were due in the first quarter of FY86. A navy program review during the summer of 1986 concluded that it was impossible to develop a satisfactory unitary missile and, moreover, that it was unwise to develop a totally new very long range surface-launched surface-to-air weapon. Instead, effort would be concentrated on a new long-range air-to-air missile (AAAM) and on an evolutionary improvement of SM-2, which became SM-2 Aegis (ER). AAAM was separated from ASAM.

◆ LORAINÉ

LORAINÉ is an experimental program sponsored by DARPA: the letters mean Long-Range Aircraft Interceptor Experiment. LORAINÉ is intended to attack targets at very long range with nonnuclear weapons and, therefore, is a candidate technology for the navy's Outer Air Battle project. There are also possible air force applications, for example, as part of the Air Defense Initiative (ADI, the air-breathing complement to SDI). In common with other DARPA projects, LORAINÉ is a technically risky attempt to achieve a dramatic improvement in overall performance.

From the sketchy information available, it appears that LORAINÉ is a ballistic weapon sized to fit the standard launching cell of a Mk 41 vertical launcher. LORAINÉ boosts its reentry vehicle (the "boost-glide vehicle") above the atmosphere. As the vehicle falls back to earth, the active conformal-array radar searches over a wide area matched by its kinematic footprint. The missile has sufficient energy to connect with any conventional air-breathing craft; speeds of Mach 8–10 have been mentioned. The homing footprint might be so wide that the weapon could use target-designation data from a sensor as crude as an OTH radar. Reportedly the reentry vehicle might use a multimode seeker (e.g., active radar, antiradar, and home-on-jam). One technical problem would be to distinguish the target from the surrounding ground clutter; this problem would be for LORAINÉ a worse version of the usual look-down/shoot-down question.

Because the missile is relatively small (limited by vertical cell dimensions to roughly Tomahawk size), it is potentially quite mobile and can be carried by aircraft (Tomahawk was considered as an alternative air-launched cruise missile). Given the missile's mobility and flexibility of basing, DARPA saw LORAINÉ as a means of rapidly improving national air defenses in a crisis.

The program began formally in FY86 (\$2.5 million) as a continuation of earlier exploratory work (the SWERVE III experiment). The SWERVE III vehicle was apparently assembled at the Sandia National Laboratory (which normally concentrates on nuclear weapons and which would, therefore, be familiar with the problems of ballistic reentry vehicles); and under the FY85 program a SWERVE III test vehicle flew 600 nm to Johnston Island (20 April 1985) to verify electrical, mechanical, and thermal performance. This project was tentatively killed off in DARPA cuts for the FY86 budget, but the money was restored when another project, Teal Ruby, had to be delayed.

In FY87, \$20 million was provided, and the request for FY88–90 is \$52 million (\$18 million for FY88, \$22 million for FY89, and \$12 million for FY90) to bring the weapon to full-scale development stage. A test flight against a drone is planned for 1991. The key technology is a radar array capable of operating at very high temperature and at high speed. In the FY87 budget Congress rejected a navy request for \$16.3 million for a

study of a hypersonic wide-area-defense missile on the grounds that the LORAINÉ technology would be superior.

The original SWERVE was the Sandia Winged Energetic Re-Entry Vehicle, a Sandia-DARPA project dating from late 1979, and conceived as an application of DARPA work on a sensor-navigation problem. SWERVE was derived from several years' work to achieve standoff maneuvering capability for tactical aircraft carrying nuclear weapons. The Sandia tactical inertial-guidance and extended-range (Tiger) program used test nuclear-weapon shapes with wings, movable canards, and solid-propellant propulsion. SWERVE was a hypersonic theater-defense missile that could be surface-launched into a ballistic (exo-atmospheric) trajectory, then reenter and maneuver to attack aircraft and cruise missiles, with a large footprint at a range of 1000 nm. Initial flight tests from Kauai, Hawaii, in September 1980 used a Thiokol Strypi (XM-33 Castor I as first stage, augmented by 2 XM-19 Recruit rocket motors). The second stage ignited after the vehicle was above the atmosphere and headed downward to accelerate the SWERVE vehicle to the desired speed. SWERVE leveled off at 25,000 ft and maneuvered. Reentry speed was about 10,000–12,000 ft/sec, about half that of a ballistic missile reentry vehicle.

◆ T ASD

Rockwell's target-acquisition ship-defense system was first displayed at the U.S. Navy League show in March 1989. A sketch showed a box missile launcher surmounted by a radar dome containing a pair of radars, operating in Ku- and W-bands. Rockwell argues that guns cannot expect to destroy incoming missiles at sufficient range to avoid damage from their fragments. The next best alternative is command to line of sight-guided missiles. Rockwell's proposal shows 2 radar dishes side by side on a single pedestal, the 2 frequencies being used together to solve multipath and glint problems. Both dishes would transmit simultaneously, and the associated control system would also use data from other ship sensors, such as ESM and electro-optical devices. Rockwell has already tested the radar concept; the company's stand showed a photograph of the dual dishes (which are the same size) side by side on a test pedestal.

TASD was a product of a congressionally mandated Balanced Technology Initiative (BTI), which was intended to apply new strategic-defense concepts to tactical problems. The TASD contract was signed in the summer of 1988.

By the spring of 1990 TASD had apparently been reduced largely to a sensor program. Drawings displayed at that time showed that initially the 2 coherent radars shared a common antenna, but that the proposed production version had side-by-side antennas. At this time Rockwell claimed that the system as a whole enjoyed 100-microrad accuracy, and that its dual frequency made it effective against low-fliers and in adverse weather. The dual radar could also provide a Ku-band up-link for a command-guided missile. Rockwell proposed it as a fire-control sensor for a 5-in gun or an electro-thermal gun (ETG). One drawing suggests a final configuration in which an electro-optical sensor is mounted atop the 2 radar dishes.

Further data were not available; it is not clear whether Rockwell has a specific command-guided point-defense missile in mind.

◆ MIRACL

Although not currently a satisfactory weapon, the Mid-Infrared Chemical Laser has shot down drones in tests, and presumably it is intended as the forerunner of future U.S. naval laser weapons. In 1985 Congress rejected a navy request that MIRACL be developed as the basis for a future naval tactical directed-energy system; the laser project was left alive largely by its connection with the SDI program. In current form, MIRACL reportedly occupies several acres.

The first successful test was on 18 September 1987 against a target drone flying at 500 kt and at an altitude of 1500 ft. On 2 November MIRACL shot down a BQM-34S drone at twice that first range; figures were not disclosed.

On 23 February 1989 MIRACL, using a Sea Lite beam director, destroyed a supersonic drone (later identified as a Vandal, a converted Talos ramjet missile) at what was described as a realistic tactical range. MIRACL had destroyed subsonic targets in the fall of 1987 but never a supersonic one. The press release issued at the time stated that the laser lethality demonstrated in the test had been predicted and tested against static missile parts but never against a real high-speed target. The 1989 test was the culmination of a 2-yr program. MIRACL itself is much too massive to use at sea, and Sea Lite is also quite massive, but the successful test, conducted at White Sands Missile Range, may provide motivation for a usable tactical system.

The tactical problem is quite different from the strategic or space-based laser problem. A missile warhead damaged in space may well burn up as it reenters the atmosphere, so relatively low damage levels may suffice. On the other hand, that damage must be imposed at very great ranges, on the order of thousands of miles. In contrast, a tactical laser hits its target at relatively short range, but the lethality must be very great, since a pinhole fatal in space may have no effect whatever on a large aerodynamic missile. The destruction of the Vandal is particularly impressive because it is so large and robust a missile. The precise damage mechanism involved is still of interest. For example, if the laser destroyed the Vandal by igniting its fuel tanks, then the result may not be generally applicable. If, however, the laser literally melted large areas of the missile's surface, the result is much more significant. The possibility of countermeasures such as defensive types of missile construction remains open in either case, however.

Proponents of a naval air-defense laser can point to the massive power supply available on board ship and to a ship's great reserves of space and weight. For example, much of the weight of the laser might be carried well below decks, with only the optical path of the beam emerging into a beam director above decks. Compared to a conventional missile, the laser promises lethality down to zero range. Compared to a small-caliber gun, the laser greatly simplifies the fire-control problem, presumably destroying the target so thoroughly that there is no danger of fragments traveling on to damage the ship. The 3 great technical issues are probably propagation through the water vapor-laden air near the sea's surface (e.g., shooting down sea-skimmers); the rate of fire (i.e., providing enough energy for quick multiple engagements); and the sheer mass of the beam director.

The MIRACL test against the Vandal drone was conducted under the congressionally mandated Balanced Technology Initiative (BTI), an attempt to apply SDI technology to conventional warfare.

The MIRACL laser was developed by TRW and uses a Hughes beam director (Sea Lite). Sea Lite was conceived for research toward a laser CIWS, as the culmination of a series of navy studies of chemical and gas dynamic lasers. The navy had also worked on at least 2 particle-beam weapons, Seesaw and Chair Heritage. In 1973 TRW won a competition with a deuterium-fluoride CW laser, operating at 3.8 microns (350 kW). It shot down a TOW missile in 1978, exciting navy interest in a laser CIWS. Hughes received a contract for a pointer-tracker. In FY81, however, the program was moved back from advanced to exploratory development, and about a third of the requested appropriation was cut by the House of Representatives. The move to White Sands Missile Range began in FY82, and MIRACL moved from the naval tactical program to the SDI program. In September 1985 it destroyed the second stage of a Titan missile booster on the ground at a reported range of about half a mile. The laser first ran at full power on 19 August 1986. In the successful Vandal test, the laser destroyed vital components, causing the missile to spin into the ground.

The laser fuels are ethylene, hydrogen, and NF₃; TRW estimates the cost per kill at \$10,000.

As of 1990 the 2 developing companies were attempting to convince the U.S. Navy to test a defensive laser at sea. TRW displayed a model of a possible ship-defense laser at the 1990 U.S. Navy League show. Although MIRACL itself stretches over

a considerable desert area, TRW claims that a practical version would be no larger than a 5-in/54 gun or a vertical missile magazine. It would not displace the gun or the missiles, since the gun would still be needed for shore bombardment, and the missiles to deal with targets above cloud cover. The laser would be aimed by an imaging tracker telescope.

◆ U.S. Missile Launching Systems

The principal current types are Mk 10, 11, 13, 26, 29, 41, and 43.

Mk 10 standard DDG and CG Terrier launching system, for SM(ER) (originally Terrier) missiles. The missiles are stowed horizontally without their booster fins, in 20-missile rotating rings. They are raised onto parallel monorails for ramming onto the launcher (through armored doors), and the boosters are finned manually. Rate of fire: 4 rnds per minute (1 missile every 30 sec per rail); typical weight, including missiles and fluids, 400,347 lb (275,875 lb without missiles). Mod 1 has 2 rings; Mod 2, the superfiring launcher in the cruiser *Long Beach*, has

Mk 10 missile launcher. The ready service mechanisms are the rotating rings carrying the missiles. Other versions of the Mk 10 launcher employ 2 or 4 rings.

A missile in a Mk 10 launcher, waiting to be finned before being rammed out onto the rails. Below it can be seen the blast doors leading to the rotary magazine; the stations at either side are for the men who ram the fins onto the missile booster. The fins are too large to fold for stowage, and the operation of finning slows the firing rate of the launcher. (U.S. Navy)

4 (80 missiles: 695,329/450,857 lb); Mods 3 and 4 were for the carriers *Kitty Hawk* and *Constellation* (now removed); Mods 5 and 6 (2 rings, 40 missiles) are on board *Leahy*-class cruisers. Mods 7 and 8 (*Belknap*-class cruisers) have 3 rings (60 missiles) and fire both surface-to-air missiles and ASROC (20 ASROC can be interspersed with the missiles on the 2 upper rings). This system was called ASTER. Weight: 546,734/361,994 lb. Complement: 16. Dimensions, for a 2-ring installation: 360 × 395 in (magazine, not counting launcher). Train rate: 30 deg/sec (elevation rate 20 deg/sec; limits +90/-10 deg).

At the U.S. Navy League show in 1990 FMC displayed possible new applications for the existing Mk 10 launcher: firing a ballistic rocket, or firing a flechette rocket (80 flechettes per round) for antiship missile defense. Interest in shore bombardment recalls a late 1960s project for a shore-bombardment missile, which would have been fired from the missile launchers of obsolescent missile cruisers.

Mk 11 twin-arm SM(MR) (originally Tartar) launcher, virtually automatic because the missiles did not have to be finned. Mk 11 was, however, considered unreliable, and it was superseded by Mk 13. The 42 missiles are stowed vertically in a 196-in diameter (209 in high) magazine. Total weight: 201,370 lb loaded, 148,450 lb empty. Crew was 3, and rate of fire one 2-missile salvo every 18 sec. This launcher can also fire Harpoon missiles.

Mk 11 missile launcher. (U.S. Navy)

Mk 13 current standard SM(MR) launcher, with a single arm, first installed in late *Adams*-class missile destroyers. Mk 13 fires 1 missile every 10 sec (continuous salvo rate is 1 missile every 7.47-7.82 sec in the Mod 4 in the *Perry* class). The 40 missiles are stowed vertically, in 2 concentric rings (Mk 22, below, is in effect the inner ring of a Mk 13). Both the rings and the launcher rotate, the blast door is fixed. Train rate: 90 deg/sec (elevation rate 45 deg/sec); elevation limits are +95/-15 deg (+93/-15 for Mod 4). Diameter: 203 in. Weight (Mod 4): 134,704 lb empty. Mod 4 was designed specifically to fire Standard Missiles, which require no warm-up, and, therefore, lacks the warm-up connectors of earlier versions. This launcher can fire Harpoon missiles.

Besides the elimination of all the warm-up circuits and hardware, Mod 4 has a new solid-state (rather than relay) control system and a means of automatically identifying the missile in each magazine position (which is necessary for a launcher firing different types of weapons). Mod 4 can identify any 7 out of a possible total of 64 missile types. Two zener diodes within each missile have reverse breakdown voltages related to binary codes assigned to missile versions based on their warhead, fuzing, guidance, and propulsion. The missile automatically identifies itself to the guide arm as it is loaded onto the launcher.

Mk 16 ASROC "pepperbox," carrying 8 missiles in 2-missile cells elevating separately. Maximum rate of fire is 3 missiles/

Mk 13 Mod 1 missile launcher. The missiles are carried in the two concentric rings surrounding the central column. (FMC)

min. Elevation limits: $+85/-3$ deg. This lightweight launcher is often criticized for its vulnerability to weather damage. Most versions are reloadable; in *Knox*-class frigates the magazine is under the bridge, abaft the launcher, and the missiles are stowed horizontally. In *Spruance*-class destroyers, the magazine is under the launcher, the missiles are stowed vertically, and the launcher elevates to 90 deg to reload. The *Spruance* version was designed specifically so that it could later be replaced by Mk 26 Mod 0. Instead, these ships are being fitted with 61-cell vertical launchers to hold 45 Tomahawks and 16 Vertical-Launch ASROCs.

Mk 21 The Polaris A3 missile-launching system survives only in the Royal Navy. Unlike its predecessors, but like all later U.S. strategic-missile launchers, it uses a gas generator to expel missiles.

Mk 22 lightweight single-arm SM(MR) launcher, for *Brooke*-class frigates and for the Spanish *Baleares* class, carrying 16 missiles in 1 fixed vertical storage ring (the blast door revolves). Rate of fire: 7/min. Train rate: 85 deg/sec (elevation 45 deg/sec); elevation limits: $+85/-10$ deg. Magazine diameter is 146 in. Weight (empty): 94,003 lb.

Mk 24 Poseidon C-3 launching system.

FMC is currently studying a variety of modified standard launchers, including the proposal to mix Standard Missiles and 2-RAM strongbacks in a Mk 13 magazine, illustrated here. The RAMs could be ripple-fired, and the strongback ejected as soon as they had been fired. FMC has proposed similar modifications to Mk 10, 22, and 26 launchers. The Mk 13 project is being funded as part of the *Perry*-class improvement program. (FMC)

Mk 25 BPDMS (initial Sea Sparrow) launching system, consisting of ASROC boxes on a former 3-in/50 twin mount (2 outboard, 2 between the vertical arms of the mount), all elevating and training as a unit, carrying 8 Sea Sparrows and firing them at a minimum interval of 2 sec (all in 16 sec). There is no means of automatically reloading. Training rate: 30 deg/sec (elevation rate: 24 deg/sec); elevation limits $+65/-15$ deg). Total weight: 31,500 lb. Mod 1 has frangible doors.

Mk 26 twin-arm dual-purpose (SM and ASROC) launcher, used in place of Mk 13 on *Virginia* and *Ticonderoga* classes. Missile length limit is 200 in (diameter 14.75 in, weight 2200 lb, compared to 13.5×186.45 and 1500 lb for Mk 13). Missiles are stowed vertically, in 2 parallel chains running fore and aft under the launcher. Rate of fire per arm reportedly approximates that of Mk 13 (in theory a Mk 26 can fire 2 missiles every 10 sec). Train rate: 90 deg/sec (elevation: 50 deg/sec). Three versions: Mod 0, 24 missiles (193,022 lb/162,302 lb empty, largely for ASROC); Mod 1, 44 missiles (264,897/208,577 lb); and Mod 2, 64 missiles (337,031/255,111 lb).

Mk 29 NATO Sea Sparrow launcher, more compact than Mk 25 and considerably lighter (12,768 lb), firing 1 round every 2 sec. Train rate: 40 deg/sec (elevation 65 deg/sec), elevation limits $+85/-5$ deg.

Mk 32 Standard Missile box launcher, for *Asheville*-class gunboats (Mods 0 and 1) and for the Iranian destroyers *Babr*, *Palang*, and *Damavand* (Mod 2). Mk 32 is fixed in train and elevates to an angle of 25 deg for firing, with a maximum rate of fire of 2 rnds/min (2 rnds per launcher, in a magazine forward of the launcher proper). Total weight: 22,420 lb. The launcher is 205

Mk 16 is the standard ASROC launching system, shown on board the frigate *W. S. Sims* (1986) and on board the missile destroyer *Farragut* (1987). Each pair of cells elevates independently. (S. Terzibaschitsch and W. Donko)

in long, with a 203-in magazine, and the launcher itself is designated Mk 134.

Mk 35 Trident C-4 launcher for strategic submarines.

Mk 36 SRBOC chaff launcher (130-mm, 40-lb cartridge). The launcher itself is Mk 137.

A standard Mk 25 launcher for the Basic Point Defense Missile System, on board the helicopter carrier *Tripoli*, July 1984. The girder in the background carries a ULQ-6 jammer. (Zeitlhofer)

Mk 26 Mod 1 missile launcher, showing a variety of weapons (Standard, 2 kinds of ASROC, and Harpoon) and the strike-down hatch at the right, with a Standard Missile being loaded. The missiles are carried on a pair of vertical conveyors, 1 for each launcher arm. (FMC)

Standard Missiles on a Mk 26 launcher, USS *Callaghan*, 1988. (W. Donko)

A Mk 29 Sea Sparrow launcher on board the frigate *Van Kinsbergen*, 1990. (L. van Ginderen)

Mk 37/38/39 launchers for CAPTOR mines from, respectively, surface ships, P-3 aircraft, and submarines.

Mk 40 Training launcher system for Iranian Navy (to train on Mk 32 launching systems).

Mk 41 Vertical Launching System (VLS), conceived in 1976, and first installed operationally on board the cruiser *Bunker Hill* (CG 52). The system was originally designed to fire only Standard Missiles, using a 228-in canister (which allowed for future expansion). However, it was decided that all VLS would also be able to launch Tomahawk missiles, so the standard canister slot was enlarged, to a length of 264 in. Standard Missiles are, therefore, loaded in short canisters with a 37.5-in adapter; all canisters are 25 in² in cross section. There is also a short canister, 144 in long, e.g., for Vertically Launched Sea Sparrow (4 missiles per canister space). This canister has not yet been used but has been proposed for the NATO frigate. Maximum missile size is 22 × 220 in (2500 lb).

Launchers are assembled from modules (8 cells each, in 2 rows of 4; but each group also includes one 5-cell module with a 3-cell strike-down crane). The usual combinations, then, carry either 29 or 61 missiles. Each module carries its own launch sequencer, motor control panel, and gas exhaust system. When a missile is fired, it exhausts through the canister blowout cover into the plenum and then up through the deck between the 2 rows of cells. The plenum can withstand 7 firings per cell plus a restrained firing from any other cell. The Mk 41 is said to cost half as much as a Mk 26 (cost per missile) and to require fewer crew (8 guided-missile mates on the *Bunker Hill*, 11 on an earlier Aegis cruiser).

Rate of fire is reportedly 1 missile/sec.

Vertical-launcher cells ready for installation.

Because the cells are large enough to accommodate a Tomahawk, they are considerably larger than a Standard Missile. At the 1990 U.S. Navy League show, FMC, the manufacturer, displayed a cell holding 2 slightly slimmed SM-series missiles (arranged diagonally), which were described as a General Dynamics proposal for a possible follow-on to the current SM-2(MR) for the mid-1990s.

Successful 4-pack launching of Sea Sparrow missiles was demonstrated as part of the NAAWS program. Given sufficient reserves of topweight, an Aegis ship could presumably stuff some of her vertical cells with the new version of Sea Sparrow (RIM-7P), which has an up-link compatible with that of SM-2.

FMC's concept for 4 boosted Sea Sparrows in a single vertical launcher cell. (FMC)

The FMC/GD "dual pack" proposal: to pack 2 of a more compact version of SM-2 in a single vertical launcher cell, doubling a ship's missile capacity. (FMC)

Mk 42 Countermeasures launching system.

Mk 43 box launcher for 21 RAM (RIM-116) point-defense missiles on a Phalanx chassis, part of ASMD Weapons System EX-31 (the system is often described as EX-31).

Mk 44 Tomahawk armored box launcher (for Tomahawk Weapons System Mk 32). Mod 1 was the ground-launched system (GLCM), now obsolete, and Mod 2 is the shipboard launcher.

Mk 44 armored box Tomahawk launchers on board the battleship *Wisconsin*, 1988. (S. Terzibaschitsch)

Mk 45 Tomahawk vertical launching system for submarines.

Mk 45-46 Trident D-5 launchers.

Mk 48 Sea Sparrow vertical launching system (using the Mk 164 launcher). Mod 0 is in the Canadian "City"-class frigates; Mod 1 is in the Dutch M-class frigate; and Mod 2 is in the Greek MEKO-200 frigate. Mk 48 has now (1989) been chosen for LHD 5, planned for the FY91 program. Mod 0 consists of 2 individual cells with exhaust uptakes between them. Mod 1 has paired cells with uptakes alongside. Mod 2 is 16 cells concentrated in 4 rows, with paired uptakes between the first and second and the third and fourth rows. The Mod 0 and Mod 1 installations are designed to be placed along a ship's side; Mod 2 is a centerline installation. Mod 0 dimensions: total height 190 in, total width 89 in, depth 52 in. These figures include the dual manifold between the 2 cells. The total weight of a 16-missile system is 34,393 lb. For the basic 2-cell launcher, 2 canisters weigh 1450 lb, 2 missiles 1100 lb, exhaust control 725 lb, ship-board mounting interface 800 lb; the total for 2 cells 4075 lb. The system as a whole requires one missile-launch controller (825 lb) and one electrical interface (242 lb). The total is 34,393 lb. Each controller can accommodate 2 fire-control systems, 16 missiles, and 8 electrical interface units.

Mk 49 RAM (RIM-116) box launcher (21 rnds) for large amphibious ships, which use canisters longer than those of the Mk 43. Total weight is 8960 lb.

Mk 50 Launching system for SLQ-49 "rubber duck" decoy. Even-numbered Mods (0, 2, 4) include 2 Mk 166 launchers, 1 on each side (total weight is 600 lb). Odd-numbered Mods (1, 3, 5) include 2 Mk 166s on each side (total weight is 1200 lb).

Mk 52 Decoy launcher for the PBC patrol boat, including two 6-barrel Mk 137 SRBOC launchers.

AIR-TO-AIR MISSILES

FRANCE

◆ Super R 530

Dimensions: 26 cm × 3.54 m; span 90 cm (530D: 26 cm × 3.8 m × 87.5 cm) [10.2 × 139.4 × 35.4 in {10.2 × 149.6 × 34.4 in}]
Weight: 250 (265) kg [551 {584} lb] **Warhead:** 30+ kg [66+ lb]
Propulsion: dual-thrust rocket (2-sec boost, 4-sec sustain)
Speed: Mach 4.5 (5.0)
Range: 35 (45) km; ceiling 21,350 (24,400) m [38,300 {49,200} yd; 70,000 {80,000} ft]

Data refer to 530F, with 530D data in parentheses as shown.

R 530 is the standard French heavy air-to-air missile, currently carried by Crusader carrier-based interceptors. R 530 is

A Super 530D missile, with Magic 2 in the foreground. (Author)

broadly equivalent to the U.S. Sparrow. The 530F version is semiactive and is carried by the Mirage F-1 fighter with its Cyrano IV X-band monopulse radar. The 530D is carried by the Mirage 2000, which has an RDM multimode radar (for export) or an RDI radar (for the French Air Force).

The Super 530 missile can maneuver at up to 20 Gs (at 17,000–18,000 m in altitude) or 6 Gs (27,000-m altitude). The 530F version can snap-up (rising 9000 m to 27,000 m). The 530D can also snap-down.

Work began in 1958, and the original R 530 was in service in 1963. Design of the improved Super 530 began in 1968; development began in January 1971, and trials of the AD 26 seeker in September 1972. The first guided firing was in 1975, and production began in 1980. The first Super 530D with RDM pulse-doppler radar was delivered in May 1983, and the missile became operational (on board Mirage 2000 fighters) in mid-1986.

◆ Magic (R 550)

Dimensions: 16.4 cm × 274.8 cm; span 66 cm [6.4 × 108.2 × 26.0 in]
Weight: 89 kg (Magic 2: 90.7 kg) [196.2 {199.9} lb]
Warhead: 12.5 kg (including 6-kg HE) [27.6 {13.2} lb]
Propulsion: single-thrust rocket, 1.9-sec burn
Speed: Mach 2+
Range: 10 km (minimum range 300 m) [range 1000–11,000 yd]

Magic is France's current, standard IR-guided missile, carried by Super Étendard strike fighters and by Crusaders. It can be launched at airspeeds of up to 700 kt and is credited with a maximum maneuverability of 30 Gs. The IR seeker is nitrogen-cooled. Typical range is 2.5 km [2750 yd] at medium altitude, or 10 km at high altitude.

The French Rafale fighter carries Magic 2 missiles on its wing tips, with 4 Matra MICAs under its body. (MATRA)

Magic 2. Unlike Sidewinder, Magic 2 has no air-driven gyros on its tail fins. (Author)

The improved Magic 2 entered production in September 1984. It has a better detector (80–100 times as sensitive) and can be slaved to the aircraft's fire-control system. The maneuverability limit is increased to 50 Gs. In February 1990 a Magic 2 was fired by a fighter flying at Mach 1.3 at 20,000 ft, pulling 8 Gs, which was reportedly close to the edge of its flight envelope.

Magic was conceived as a private-venture replacement for Sidewinder. Concept and feasibility studies were carried out in 1966–68, and the French government let a development contract in 1969. The first guided launch was in January 1972. The 1000th missile was delivered in December 1976, the 2000th in November 1977, the 3300th in March 1979, the 4500th in August 1980. More than 8000 have been manufactured for at least 18 countries; 75% of total production is for exports. Magic was first used in combat, in the Persian Gulf War, in August 1980. There, Magic is carried by French naval aircraft and Indian Sea Harriers.

In 1988 estimated cost per missile was \$175,000 (\$200,000–\$250,000 for Magic 2).

◆ MICA

Dimensions: 16 × 310 cm [6.1 × 122 in]

Weight: 110 kg [242 lb]

Warhead: 12 kg [26.4 lb]

Propulsion: solid-fuel rocket

MICA is to replace both Magic 2 and Super 530; it will arm the next-generation French Rafale naval fighter. The missile has 2 interchangeable homing heads, active radar and IR. Data above refer to the radar version. Like its competitor, the U.S. AMRAAM, MICA has a preset autopilot and an inertial reference system, for multitarget engagement with mid-course update. Matra claims that its long wings particularly suit it to flight at high angles of incidence, for steep climbs and dives (snap-up and snap-down shots). The seekers are designed to lock onto targets far off bore sight at short range. The missile steers

The 2 versions of MICA, radar (top) and IR (bottom). Note that the tail fins are very similar to those of Super 530. Control vanes are visible in their exhaust nozzles. (Author)

by a combination of aerodynamic (tail control) and direct-thrust control (using 4 vanes in its nozzle). Modes: multitarget engagement at long range (mid-course update), medium-range multitarget engagement (no mid-course update, but the missile may lock on after launch), dogfight, and self-defense. In the last mode the missile automatically locks onto targets as much as 90 deg off bore sight, so a strike airplane need not turn away to engage an enemy aircraft. Matra is prime contractor, with radar guidance developed by Electronique Serge Dassault (ESD) and Marconi Defence Systems (which has a 30% share); the IR seeker is being developed by SAT and Matra. Matra points out that MICA is so light that it can be carried on wing as well as fuselage. Rafale should be able to carry 6 (wing tips and under body), and similarly an F/A-18 should be able to carry 6 (underwing and under body; the Matra brochure does not show MICAs at the F/A-18's wing tips).

Matra offered a modified MICA with an IR seeker as an alternative to the ASTER series (which was adopted as the SAAM/FAMS missile). Several such missiles could fit a single Crotale tube, just as several RAMs can fit a single Sea Sparrow cell.

Studies of the next generation French air-to-air missile began in 1979–85, and Matra was awarded a development contract late in 1985. The missile was ground-qualified in 1989, and air-to-air firings began in 1990, from a Mirage 2000. As of mid-1990, the active radar version of MICA was scheduled for availability at the end of 1993.

INTERNATIONAL

◆ ASRAAM (AIM-132A)

ASRAAM, or Advanced Short-Range Air-to-Air Missile, was the Sidewinder replacement envisaged in an August 1980 MoU among the United States, Britain, and Germany. Under this MoU, the United States would develop the parallel Sparrow replacement, AMRAAM, and it would agree to adopt an Anglo-German Sidewinder replacement, ASRAAM. However, as of 1990 the future of the missile project was extremely uncertain, the German government having pulled out of the project in July 1989. Germany would have provided more than 40% of total development funds. Its withdrawal was due largely to the escalating cost of other programs such as PAH-2 and EFA. The U.S. Air Force closed its ASRAAM project office in 1990 as part of its FY90–91 budget cuts, but as of the spring of 1990 it was not yet clear whether the United States still plans to buy some ASRAAMs as its part of the MoU.

Norway joined the program in 1986, and Canada in 1987. France has observer status. Germany was to have contributed over 40% of the total, with a similar share from Britain, 10%

ASRAAM mock-up on a British Sea Harrier. The United States is trying to avoid using the launch-rail adapter. (British Aerospace)

from Norway, and 3–4% from Canada. Italy and Spain had shown some interest earlier, but in 1989 neither was directly involved in the program. Planning was based on a U.S. requirement for 40,000 missiles, compared to 15,000 in all for Britain, Germany, Norway, and Canada. The German share was 4495 rnds, at a projected unit cost of DM 200,000 (something less than \$100,000).

During 1988 the national armaments directors of the United Kingdom and West Germany decided to transfer prime responsibility from Germany to Britain. The decision did not affect work shares, but the ASRAAM became more clearly a leader-follower program. In return, Euram, the company responsible for AMRAAM production in Europe, moved from Britain to Germany; the partners in Euram are MBB, AEG, BAe, and Marconi Defence Systems.

BAe, which had already carried out considerable development of projected Sidewinder replacements for the Royal Air Force and the Royal Navy, under the SRAAM (short-range air-to-air missile) program, was prime contractor, with the German firm, BGT (which had manufactured Sidewinder under license) as the main subcontractor. When the Germans withdrew, BAe sought new partners, and Thomson-CSF reportedly offered to develop a new seeker, in place of BGT. Early in 1990 BAe was negotiating with Hughes to form a new ASRAAM consortium.

SRAAM used thrust-vector control and had a dual-mode (radar and IR) seeker. Published photographs of the ASRAAM model show fin control. Reportedly, the missile will use a triaxially stabilized IR seeker capable of all-aspect acquisition and tracking, and of discrimination among multiple targets. The missile will be slaved either to the aircraft's search radar or perhaps to the pilot's helmet, and will probably be locked on before launch. There may also be a lock-on-after-launch mode, the missile being fired outside its FOV. The missile's seeker may also be used as an alerting IR sensor while searching from its launch rail, e.g., for an airplane not equipped with a search radar (or not using its radar, for electronic silence). Photographs show a wingless missile, presumably using body lift in flight; and the motor will probably be a boost-sustain type to provide sufficient energy for terminal maneuvers.

ASRAAM is to have an IIR head, but it has not yet been decided whether it will be strap-down or gimballed. Current British seekers provide a picture consisting of 64×64 pixels; Hughes has demonstrated a 256×256 -pixel array. This level of imaging makes jamming difficult, and also makes it easier to provide off-boresight capability. As of mid-1988, reported performance includes: 20–50-deg off-boresight capability, speed about Mach 2.5, 10-G maximum maneuverability. Reportedly, this performance may be within the capability of an updated Sidewinder.

The U.S. DoD has complained about the slow pace of ASRAAM development. DoD also wanted ASRAAM and AMRAAM to be interchangeable on an airplane's pylons. That requirement ruled out the Missile Support Unit (MSU) planned for ASRAAM (the MSU contained interface electronics and cooling pack). The U.S. DoD argued that at the least an MSU would have to be tested after firing an ASRAAM, because it could be damaged by the hot gases of the launch. BAe has, therefore, had to integrate the MSU with the missile, and that integration, in turn, has protracted development. As of mid-1988, completion of development was scheduled for 1989.

As might be imagined, given the very large prospective U.S. order, U.S. objections carried great weight. ASRAAM was substantially redesigned, its diameter increased from 150 to 163 mm to accommodate the equipment otherwise carried on the MSU. As a consequence, the seeker could operate longer and the nose profile was more efficient aerodynamically. The missile was given a boat tail to reduce drag. The fatter missile was stiffer, hence better able to resist whipping when fired from a wing tip, but it was also very near its weight limit. Given repackaged electronics, the fatter missile could carry a larger warhead, and there was some interest in redesigning its motor to take more propellant, by replacing the carbon-fiber casing. Even

so, there were reports in 1989 that projected ASRAAM performance (which would not enter service for some years) was no better than the performance actually being achieved by existing product-improved Sidewinders.

Late in 1989 GEC (which owns Marconi Defence Systems) proposed an ASRAAM alternative using MICA technology, both in the seeker and in the motor, which it called MICASRAAM. MICASRAAM would use thrust-vector control and a wide-angle seeker for far-off-boresight shots. It would use a cooling engine rather than 1-shot gas bottles, to activate and maintain the missile seeker throughout flight. The missile can, then, function as a surveillance device to supplement the aircraft radar. Using the inertial guidance system of the MICA missile, MICASRAAM could be locked on after launch. For example, it could be commanded into a curving path, flying under inertial control until the target entered the seeker's FOV. MICASRAAM would weigh less than 90 kg [less than 198 lb] and would be able to accelerate laterally at over 50 Gs. GEC and Matra claimed in 1990 that it can be available in 1995. In theory, the British government cannot take up this proposal until the ASRAAM MoU is abandoned or until it lapses in 1994.

In March 1988 it was reported that the United States might be developing an alternative "black" (code-word) missile that might even be ready for service before ASRAAM, which is unlikely to be available before 1995 at the earliest (despite an initial schedule requiring production in 1983 or 1984). According to these reports, the black Sidewinder-replacement program has been proceeding for some years, and there are even test airframes. ASRAAM was described as too heavy and as requiring too many modifications to the aircraft intended to carry it. Reportedly, the U.S. alternative program is classified partly because the U.S. services do not want other multinational programs, such as the Modular Stand-Off Weapon, jeopardized.

USSR

The new Soviet carrier *Tblisi* will probably carry a mix of Su-27 (Flanker), MiG-29 (Fulcrum), and Yak-41 (Forger follow-on) fighters, of which the Su-27 and MiG-29 both have long-range doppler radars and carry a variety of air-to-air missiles. The current Yak-38 (Forger) is credited with the ability to carry the AA-8 Aphid only, the Soviet equivalent of Sidewinder.

Su-27 is a long-range national air-defense (PVO) fighter and has also been used to escort Su-24 (Fencer) attack bombers. Its likely naval roles would be bomber escort (to prevent U.S. F-14s from executing their outer-air-battle mission) and possibly a contribution to the national air-defense system. The latter role has often been discussed by Soviet writers but may well owe more to current official interest in "defensive insufficiency" than to any operationally realistic scenario. However, unless the Soviet carrier operates AEW aircraft (which will be difficult in the absence of a catapult), any interception role will have to depend on cooperation with land-based aircraft. That is not impossible; the U.S. Navy operated land-based AEW aircraft (EC-121 Warning Stars) until the early 1960s, i.e., until it could obtain sufficiently sophisticated carrier-based types. U.S. naval forces currently enjoy cooperation from land-based AWACS aircraft.

Su-27 is not quite equivalent to the F-14, since the Soviet plane has only a single seat and lacks a very long range equivalent to the U.S. Phoenix. However, in the PVO it replaces the very large, very long range Tu-28 (Fiddler), which was a 2-seater.

An Su-27 carries up to 10 missiles, including pairs of AA-10 A/B/C and 4 AA-8s (Aphids) or AA-11s (Archers).

MiG-29 is a much shorter range and much more maneuverable airplane, more like the U.S. F/A-18 in size and in character. Armament is 6 AA-10s or AA-11s underwing, plus provision for AA-8s and AA-9s.

Both aircraft also carry 30-mm cannon.

Soviet air-to-air missile development practice is to provide parallel IR and semiactive radar versions of the same airframe. Standard doctrine is to fire 2 missiles to achieve a reasonable probability of kill, and to mix the 2 main guidance techniques

for the same reason (partly on the theory that countermeasures will be deployed against one or the other, but not against both). Typically, then, a fighter will fire an IR missile first (otherwise the IR missile would home on the tail of the semiactive one). However, the IR missile cannot be locked on nearly as early as the semiactive one (note the comparative ranges, where figures are given), and a typical U.S. view would be that the mixed tactics unduly limit a fighter's maneuvers.

♦ AA-8 Aphid (R-60)

Dimensions: 13 m × 2.0 m; span 52 cm [5.1 × 78.7 × 20.5 in]
Weight: 55 kg [121 lb] **Warhead:** 6-kg HE [13.2-lb]
Propulsion: solid-fuel rocket **Speed:** Mach 3.0
Range: 7 km [7650 yd]

AA-8 is the Soviet equivalent of the modern versions of Sidewinder, replacing the earlier AA-2 Atoll. Although Aphid exists in both IR and radar-guided versions, only the IR version is probably carried by Forger carrier-based VTOL fighters.

There is some evidence that AA-8 lacks lethality. For example, in October 1988 an AA-8 failed to kill a British Aerospace 125 business jet carrying the president of Botswana, when the missile was fired by an Angolan MiG-21. The missile is smaller than a Sidewinder and cannot be launched head on.

The current version is R-60MK. This missile is now being replaced by a new R-73 (AA-11).

An AA-8 (R-60) missile on display at Farnborough, 1990. In the background are AA-11s and an AA-10. (Author)

♦ AA-10 (Alamo, R-72)

Dimensions: 7 × 158 in (126 in for short-range versions) [18.5 × 400/320 cm]
Weight: 441 lbs (342 lb short-range) [200/155 kg]
Propulsion: solid-fuel rocket; boost-sustain in long-range version
Speed: Mach 4.0 (Alamo B: Mach 3.5)

This missile replaces the AA-5 (Ash) carried by the previous heavy PVO fighter, the Tu-28, as well as the AA-3 (Anab) of the single-seat Su-15 (Flagon) PVO fighter. MiG-25/31 interceptors carry a much larger missile, AA-6 (Acrid). The AA-10's configuration is unusual, with inverse-tapered wings abaft small strake foreplanes, and with the usual (but short-span) tail fins. It is officially described as conferring good maneuverability at high angles of attack.

There are 4 versions:

- | | |
|---------|--|
| Alamo A | Short-range semiactive-radar (standard in MiG-29) version. |
| Alamo B | Short-range IR version. |
| Alamo C | Long-range semiactive-radar version. |
| Alamo D | Long-range IR version. |

The difference between long and short range is in the length of the rocket motor, hence its burn time. The longer-burning

An AA-10 (R-72R) missile on display under the wing of a MiG-29 at Farnborough, 1990, with AA-11s outboard. Note the characteristic inverse-tapered wings. (Author)

motor may also be used to provide the missile with greater terminal maneuvering power at constant range. In the radar version, the longer motor is probably intended to take advantage of the higher illuminating power available in an Su-27. Since AA-10 is a very new missile, it is apparently assumed that it uses an inverse-monopulse seeker, like that of current Sparrows.

In 1988 it was reported that in recent U.S. Air Force exercises the head-on range of Alamo was assumed to be 6–8 nm, rather than the 20 nm of late models of Sparrow. However, later estimates were 30 km [16.5 nm] for the A and B versions and 45 km [25.5 nm] for the C and D versions. At Farnborough in 1990 a Soviet aircraft designer credited AA-10 (presumably the radar version, which was on display) with a range of 60 km [32.8 nm].

The earlier Soviet AA-7 (R-23) missile, which arms the MiG-23, is a 1970s missile broadly equivalent to the original Sparrow III, albeit much larger (8.75 × 181 in, with 42-in span; 705 lb with an 88-lb warhead). Range was about 20 nm or 22 nm in the semiactive version (R-23R), and 12 nm in a look-down mode. As in other programs, there is also an IR version (R-23T). Presumably, the difference between AA-7 and Sparrow is explained by much less compact Soviet electronics, and also possibly by much less efficient solid fuels (it takes a larger motor to get worse performance, in this case Mach 3).

AA-10 entered service in 1984, and initially it was described in the West as a developed version of AA-7. However, it has an entirely different configuration.

Soviet military designations: R-72R and -72T are the radar- and IR-guided versions of the basic missile; R-72ER and -72ET are the longer-range versions. The industrial designator is Izdeliye (Object) 470. The R-27 designation sometimes published for this missile is probably a misprint.

♦ AA-11 (Archer; R-73)

Dimensions: 130 mm × 2.13 m [5.1 in × 7 ft]
Weight: approx 45 kg [100 lb]
Propulsion: solid-fuel rocket (boost only)
Speed: Mach 2.5

This new short-range, dogfight missile was first reported in 1986; it replaces AA-8 and is probably broadly equivalent to recent Sidewinders (AIM-9L/M), to which it is similar in size and configuration. However, at least 1 report credits it with thrust vectoring for very high maneuverability. It should offer better lethality than AA-8, and also better performance (including forward-aspect attack).

At Farnborough in 1990 a Soviet aircraft designer credited this missile (presumably the IR version, which was on display) with a range of 20 km [10.9 nm], a capability to maneuver at 60 Gs, and a seeker that could turn 60 deg off bore sight (this last figure may be the seeker's full FoR). The missiles on display showed

An AA-11 (R-73) missile under the wing of a MiG-29 at Farnborough, 1990. (Author)

what may have been vanes in their nozzles, for a degree of thrust control.

UNITED STATES

◆ AAAM

The Advanced Air-to-Air Missile is intended to replace Phoenix (see below) with a Sparrow-sized weapon. Two competitors have emerged: a General Dynamics–Westinghouse team and a Hughes–Raytheon–McDonnell Douglas team. Proposals were submitted in May 1987, and both contractors received demonstration/validation contracts for FY88–90, the winning team to receive its contract in FY91. Funding may make it impossible to carry both teams all the way through to flight tests.

Reportedly, the navy wanted an AAAM with a diameter of less than 9 in and a weight of less than 650 lb, with a unit cost of less than \$750,000, to attack crossing and violently maneuvering targets at ranges of 100 nm. The hope was that an F-14, which can fly with 6 Phoenix and land with 4, could land with at least 8 AAAM on board. The navy has specified a maximum AAAM-system weight of 5303 lb for the F-14D, on the basis of acceptable carrier-landing weights.

The General Dynamics project dates to the mid-1970s and began as a private venture. The company proposes a combina-

The General Dynamics version of AAAM, being fired by an F-14. (General Dynamics)

The Hughes version of AAAM, an integral rocket-ramjet. (Hughes)

tion of a small long-range 2-stage rocket missile (380 lb; 5.5 × 144 in) and an external multifunction airborne track-illuminator or ATI (16 × 142 in, 750 lb), the 2 communicating through the standard internal digital data bus already used for pods such as laser-trackers. The ATI would have a limited search capability, although usually targets would be designated to it by the aircraft's main search radar or main IR search/tracker. The ATI would have front and back antennas, so it could continue to track while the airplane maneuvered freely. Once the target(s) had been designated, the ATI would track them and compute engagement envelopes. The aircrew would select and fire missiles, which would fly out using mid-course inertial guidance. The missile's autopilot would be updated via a signal time-shared between the missiles. Missiles would transition to semi-active terminal guidance (interrupted continuous wave), and in at least some cases missiles might home by infrared (perhaps mm-wave) using a common-aperture dual-mode seeker. Missiles homing semiactively would time-share a common illuminator, just as Phoenix does.

The General Dynamics missile is so small that the company estimates that an F-14 can carry as many as 15 AAAMS, normally 6 to 9. The missiles themselves would be stowed in universal launch tubes, with their fins and wings folded. The motors would have selectable burn, i.e., they would be able to reserve fuel for terminal maneuvering. The missiles would use a combination of aerodynamic and thrust-vector control for violent maneuvering. General Dynamics claims that this approach and the ATI's ability to function as a (limited) acquisition radar make it possible to provide almost any airplane with an advanced very long range air-to-air capability.

The alternative Hughes-Raytheon missile is powered by an integral rocket-ramjet, for a high-power output throughout the flight. Hughes's missile would use a combination of infrared

The General Dynamics/Westinghouse AAAM, stowed in its universal launch tube and deployed. The ogival radome is radar transparent and would be discarded if the missile went into IR-homing mode (there is an internal hemispherical dome over the IR seeker). (General Dynamics)

AAAM envelope compared to that for Phoenix. (General Dynamics)

imaging and active-radar homing. Like Phoenix, the missile uses semiactive mid-course guidance. No dimensions (other than a length of 12 ft) are given, but Hughes describes the missile as Sparrow-sized with Phoenix or better performance ("stand-off ranges that are up to 4 times greater than current systems"). Engagement modes include launch-and-leave and silent- (pure-passive) engagement.

◆ AMRAAM (AIM-120A)

Dimensions: 7 × 144 in (wing span 21 in, tail span 25 in)
Weight: 335 lb **Warhead:** 50-lb class
Propulsion: solid-fuel rocket **Speed:** reported approx Mach 4.0
Range: reported 60,000–80,000 yd

AMRAAM (AIM-120A) with Phoenix and Maverick in the background. (Hughes)

AMRAAM's inboard profile. (Hughes)

The Hughes Advanced Medium-Range Air-to-Air Missile is intended to replace Sparrow. Much lighter than Sparrow, AMRAAM may be carried in greater numbers. More importantly, it is a fire-and-forget weapon, providing a fighter with a capacity to engage multiple targets. The missile is sent into a homing basket on the basis of data fed in before firing, supplemented by data-link data supplied by the launching fighter. Approaching the target, AMRAAM switches on its X-band pulse-doppler seeker. Long range and good maneuverability are assured by a boost-sustain motor, which replaces the boost-glide motor of the Sparrow.

In 1982 Raytheon was chosen as a second-source supplier. Although an air force project, the missile has several vital naval applications. It provides F/A-18s with the capability to engage multiple targets, and AMRAAM will probably provide late-production A-6 Intruders (A-6G and later) with a self-defense or even fleet radar-picket capability. In addition, AMRAAM has been chosen as the armament of the modernized Royal Navy Sea Harrier fighter.

AMRAAM has always suffered from very high unit cost. Hughes, the prime contractor, has suggested from time to time that the missile is the natural successor to Sea Sparrow as well as to Sparrow itself. Raytheon has suggested that the missile can never be made inexpensive enough to supplant Sparrow entirely, and that a developed Sparrow will be the basis of the next-generation NATO naval air-defense system.

The first production AMRAAM missile was delivered on 26 October 1988. The initial production lot (for navy and air force) is 180 missiles, 105 from Hughes and 75 from Raytheon.

The U.S. Navy FY89 program included 26 AMRAAMs, and the January 1989 budget proposal showed 150 in FY90 and 800 in FY91. The current AMRAAM export price is \$475,000. There is some question as to whether these missiles will be manufactured in Europe by the Euram consortium because the U.S. manufacturers, Hughes and Raytheon, are asking a 13% licensing fee. Euram may, therefore, be unable to offer a competitive price. However, during the 1989 Paris Air Show, MBB announced that it would license-produce AMRAAM, delivering the first units in 1993. This production will include weapons for Royal Navy Sea Harrier 2 fighters.

The only current foreign naval customer is the Royal Navy, which plans to carry AMRAAMs on board its Sea Harrier FRS.2 fighters, and which cannot substitute any existing medium-range semiactive radar missile. The reported current British requirement is at least 330 missiles. Very large numbers of AMRAAMs are required to replace Sparrows in current service with European air forces.

Concurrent with initial AMRAAM production, there is an AMRAAM product-improvement program. Replacement of the current electronics by custom VLSI chips should drastically reduce the number of circuit boards, and heat production is to be reduced by 90%. The current mechanical gyro is to be replaced by laser ring gyros.

Early in 1989 the Norwegian government signed a study contract with Hughes and with Norsk Forsvarsteknologi (NFT) to develop a mobile land-based surface-to-air missile system using AMRAAM, to be called NASAMS (Norwegian Advanced Surface-to-Air Missile System). Each battery will consist of 3 radars, 3 fire-control centers, and 9 six-missile launchers, the controlling radars being based on the current Hughes TPQ-36. Should NASAMS proceed to production, the modified AMRAAM developed for it would presumably become available for naval service.

Navy procurement: 26 in FY89, 85 in FY90, 550 requested (January 1990) for FY91 (unit cost \$767,000).

◆ Have Dash-2

This stealthy missile, intended as the forerunner of an AMRAAM successor, is currently under development. Ford Aerospace is conducting a 38-month program that is to end in 6 flight tests (by 3 vehicles) in March–September 1992. Although the program is being managed by the U.S. Air Force Munitions Systems Division, a missile derived from Have Dash-2 may well follow AMRAAM into naval service. Have Dash-2 is to be carried externally, blending into the skin of an airplane without destroying its stealthy shape. It, therefore, has a flat underside, 13 in wide (it is to be carried above, rather than below, the fuselage), and it also provides some body lift. For most of the missile's length its 2 upper sides are also flat (it has a triangular cross section). It, therefore, belongs to the new class of faceted stealthy missiles, the faceting reflecting most radar signals away from the transmitting antenna. Given its greater body lift, Have Dash-2 dispenses with the mid-body wings of Sparrow and AMRAAM and is limited to 4 folding tail fins. The combination of body lift, fin configuration (as in the proposed tail-control Sparrow), and new bank-to-turn autopilot should permit Have Dash-2 to maneuver at 50 Gs, compared to 35 Gs for current weapons.

The missile's length is limited to 12 ft (144 in, as in AMRAAM) to avoid interference with trailing-edge control surfaces and access doors on the F-15s and F-16s that may ultimately carry it (the test flights will be made from an F-111E equipped with a 2-piston ejector). Total weight is 400 lb. The drawing released in July 1990 shows a pointed nose similar to that of the existing AMRAAM. This shape is inherently stealthy in that it reflects radar signals away from broadside. However, if it houses a conventional planar antenna, the shape the incoming radar signal is likely to see will be the flat shape of that antenna. A conformal array might encounter fewer problems but would be more difficult to use. Have Dash-2 will not be testing new-generation stealthier sensors. It will incorporate an

inertial reference system (like that required by AMRAAM) and a new navigation-intercept computer. An operational missile derived from Have Dash-2 would use a combination active/passive radar and IR seeker. Plans originally called for Have Dash-2 to be powered by either a ducted or a pulsed rocket, in either case stealthier than the current boost-sustain engine (because its IR signature is either greatly reduced, in the case of the duct mixing air with the exhaust, or intermittent). However, in the interest of economy, flight tests will be made with AIM-7E Sparrow motors.

In July 1990 Brunswick Defense received a contract for 3 graphite-polyamide (composite) airframes for the recoverable prototypes; they are probably the first nonmetallic, supersonic missile airframes. Reportedly, 1 of the 2 major issues in the flight tests will be whether such materials are strong enough to withstand the expected speed of Mach 4+. The other question is the extent to which the unusual shape and autopilot can achieve the desired agility.

Have Dash-1 was described officially as a missile-to-airframe integration program.

◆ Phoenix (AIM-54)

Dimensions: 15 in × 13 ft (span 36 in)
Weight: 1008 lb (985 lb for AIM-54A) **Warhead:** 133 lb
Propulsion: solid-fuel rocket (single-pulse)
Speed: Mach 5.0 (Mach 4.3 for AIM-54A)
Range: 80 nm (minimum 2.0 nm) (AIM-54A: maximum 72.5 nm, minimum 2.1 nm)
Launch Altitude: 60,000 ft maximum (-54A: 48,800 ft)
Missile Max Altitude: 100,000 ft (-54A: 81,400 ft)

Phoenix missiles carried by an F-14A fighter. (U.S. Navy)

Data apply to AIM-54C version.

Phoenix, manufactured by Hughes, is the longest-range air-to-air missile in operation; stated maximum range is 86+ nm. Phoenix is carried only by F-14 Tomcats and is guided by their AWG-9 radar. The missile incorporates a programmed autopilot to fly into a basket near the target; Phoenix then picks up semi-active illumination from the launching airplane. Not needing that illumination at launch time, Phoenix can fly a more energy-efficient (up-and-over) trajectory. Moreover, not needing to pick up reflected energy at very long range, the missile can make use of an illuminating radar of reasonable power (the missile is closer to the target when illumination is needed). Illumination is intermittent, and the missile uses its X-band active seeker for terminal guidance. The combination of precomputed/data-linked initial trajectory and terminal active homing makes it possible for several missiles to time-share a single tracker-illuminator; an F-14 can engage 6 targets simultaneously.

AIM-54A was manufactured from 1972 through 1980. The only foreign customer was Iran, and it seems likely that the missile was compromised during or after the fall of the Shah. No reliable reports of Phoenix engagements during the Iran-Iraq War have come to light, but it has been reported that the Iranians have used their F-14s as airborne radar-control platforms.

AIM-54C was the second production version, incorporating 5

major improvements: digital rather than analog circuitry so that the missile can be programmed for target discrimination in stream raids, improved beam (crossing-target) capability, and improved capabilities to engage an opening target from its rear quarter; better resistance to ECM; greater range and altitude; greater maneuverability; and a fuze (target-detecting device) better adapted to detonating on small targets or very low altitude targets found in clutter such as chaff. Deliveries began in 1981, and the last of 330 were delivered in September 1986. Deliveries of AIM-54C Plus began in March 1986. This last version incorporates internal heaters.

A further improved AIM-54C Plus began development in August 1987; it incorporates a high-powered TWT (adapted from that of AMRAAM, giving 10 times the power of the earlier version), a reprogrammable memory (RPM), and a new low-sidelobe antenna with better electronics. The new memory replaces 45 chips with 6 new ultra-high-speed ones. The RPM and new software were tested in shots in September and December 1989, and the full upgrade was first tested in August 1990. The full upgrade will be incorporated in new-production missiles and will also be available in retrofit kit form.

Although designed primarily as an outer-air-battle weapon, to attack bombers rather than their missiles, Phoenix can shoot down antiship missiles. In June 1983 it was reported that in a test Phoenixes had shot down 11 of 11 Harpoons.

Current U.S. Navy policy is to maintain 2 competing suppliers of all major weapons; Raytheon was chosen as the second source, making initial deliveries early in 1988.

Like SM-2, Phoenix is designed to deal with saturation attacks. During the early 1970s, Hughes proposed a sea-based version, which some saw as a less expensive alternative to Aegis. This version was also substantially less capable, and it did not progress very far. Phoenix is ultimately to be replaced by AAAM, which is Sparrow-sized.

The basic concept of a very long range air-to-air missile was developed in 1960, and Hughes was selected in August 1962. The first guided flight (from an A-3) was in May 1966. AIM-54C's engineering development began in October 1976, with first deliveries of development missiles in August 1979. Production began late in 1982, and AIM-54C was operational in January 1984. Approximate unit costs: AIM-54A, \$750,000; AIM-54C in FY83, \$796,000, but in FY84, \$681,000. Reported inventory objectives are: 2932 AIM-54A, 7249 AIM-54C (including 45 for RTD&E). The 1000th AIM-54C was delivered 27 October 1988; this figure includes more than 600 AIM-54C+. The FY89 program included 450 Phoenix missiles; and in January 1989 the U.S. budget proposal showed 420 in each of FY90 and FY91. Current plans call for completion of Phoenix procurement in FY93, although there is some question as to whether that will make second-source production (by Raytheon) uneconomical.

Four engagements give some idea of AIM-54/AWG-9 capability. In one case, an F-14 (at Mach 0.7, 31,500 ft) intercepted 5 targets simultaneously. Four missiles were launched from 30-nm range at 4 of the 5, flying (at Mach 0.6 at 20,000–25,000 ft) in a wave-front formation 20 nm wide. One target was hit directly, and the other 3 missiles passed within lethal range.

In a second exercise, an F-14 began to track a BQM-34E drone that was using ECM (Mach 1.5 at 50,000 ft). The missile was launched into an up-and-over trajectory at a range of 110 nm, reaching a peak altitude of 103,500 ft, and flying 72.5 nm to intercept the target. The drone had been augmented to present the radar cross section of a bomber.

A third exercise simulated an engagement with a MiG-25 Foxbat (simulated by an AQM-37A at Mach 2.2 at 82,000 ft). The F-14 fired from a range of 35 nm, the missile climbing about 36,000 ft to destroy the drone.

Finally, the F-14 engaged a BQM-34A simulating a cruise missile that was flying at 50 ft. The fighter flew at 10,000 ft, and its radar operated in TWS mode; it killed the missile at a 22-nm launch range.

◆ Sidewinder (AIM-9)/Sea Chaparral

Dimensions: 5 × 112.2 in (canard span 15 in, wing span 24.8 in)
Weight: 188 lb **Warhead:** 25 lb **Propulsion:** boost-sustain
Speed: Mach 2.5 **Range:** 10,000–20,000 yd

Sidewinder (AIM-9L). (U.S. Navy)

Sea Chaparral on board a Taiwanese destroyer. (Republic of China Navy)

Data apply to AIM-9L version.

The Sidewinder is virtually the Free World's standard short-range air-to-air missile. It has also been copied by the Soviets and by the Chinese. Several other countries have developed externally similar weapons. The current version, used by the U.S. and Royal Navies, is AIM-9L/M, to which the figures above apply. Because Sidewinder (and its brethren) need very little support by the airplane carrying them, they are the natural missile armament for attack aircraft and for fighters without long-range radars, such as current Sea Harriers.

Guidance is passive infrared, with proximity and contact fuzing (the early version had only a contact fuze). There was also a semiactive-radar-guided version, AIM-9C. Stocks of this weapon have been converted to Sidarm short-range antiradar missiles (see the Strike/Surface Warfare section). AIM-9L introduced full-aspect homing, using the heat generated by high-speed flight and also the forward-aspect "glint" of sunlight on an airplane. The basis of current versions, AIM-9L is the version that proved so successful in the Falklands War, when the missile was carried by British Sea Harriers defending the fleet against Argentine air attacks.

AIM-9A (AAM-N-7) was the prototype, development of which began in 1950 at China Lake; it was conceived as a guided version of the 5-in, high-velocity aircraft rocket. The contract for seeker development was let in 1951, and the first missile flew on 11 September 1953. In September 1958 Sidewinder became the first missile to shoot down another airplane in combat, over

the Taiwan Straits. A dud brought home by a PRC MiG fighter was apparently the basis for the Soviet AA-2 (Atoll, or K-13).

AIM-9B (Sidewinder 1A) was the first production version. It became operational with the U.S. Navy in July 1956, and production ended only in 1962. Total -9B production was 80,900 by Philco-Ford plus about 15,000 under license in West Germany by Fluggeraetewerk Bodensee GmbH (now Bodenseewerk Geraete Technik) for NATO air arms. About 10,000 missiles were later updated (see AIM-9F, below). Missiles updated from 1982 on have been fitted with DSU-21/B laser proximity fuzes, described below under AIM-9L. In the early 1960s an AIM-9B cost about \$2500.

The basic mode of operation was the bore-sight attack, in which the missile seeker was caged to look dead ahead. When an IR source entered that FOV, the missile generated a tone. In theory, the pilot would then check whether the target was within the missile's kinematic flight envelope and fire. In some aircraft the missile could begin to track the target before leaving the rail, generating a chirping tone in the pilot's earphones. These audio cues, standard for all Sidewinders, were essential since the pilot could not look away during a dogfight. Only with the advent of HUDs have Sidewinders introduced visual cues (a digital display of seeker-head position and an "in range" cue based on programmed launch-zone equations).

AIM-9B had a 25-lb blast-fragmentation warhead containing 10.5 lb of high explosive (producing about 1500 fragments moving at 6000 ft/sec, lethal to 30-ft range) and contact and IR proximity fuzes. Maximum range at high altitude was about 2.6 nm, using a 4000-lb-thrust motor burning for about 2 sec; maximum speed was Mach 1.7. Range decreased to 4000 ft at low altitude. This version had an uncooled lead-sulphide (PbS) seeker with a 3.5-deg FOV, a maximum look angle of 25 deg, and a 70-Hz reticle; it could track at 11 deg/sec.

The seeker operated at short wavelengths (about 2 micron); and peak sunlight, reflected sunlight, cloud edges, and the horizon all fell into its bandpass. The dead zone around the sun was 20 deg wide. The sensitivity of the overall system imposed a 2-G limit, beyond which it could not track (maximum G-loading at launch was 2 Gs below 40,000 ft and 1.6 Gs above that altitude). The missile on the launcher rail had its seeker head caged in the dead ahead (bore-sight) direction, so it could acquire targets only within its FOV. The maximum look angle was the angle through which the seeker head could track a maneuvering target, once the missile had locked on. Most AIM-9Bs were converted to AIM-9E or equivalent standard.

Dimensions: 5 × 111.5 in, span 22 in, weight 155 lb. Maximum allowable launch range: 2.6 nm at high altitude, 4000 ft at low altitude (but see test results listed below). Minimum range is 3000 ft (reduced or increased by 300 ft for every 0.1 Mach difference in speed). These figures are for subsonic tail attacks in which target and launcher are flying at the same speed and altitude.

AIM-9Bs modified with reduced-smoke motors, for training or for special missions, are designated -9B2.

In Vietnam it was discovered that Sidewinder IA was ineffective against maneuvering targets. The missile had originally been designed to deal with Soviet bombers attacking carrier battle groups, and only in 1964 was it tested against fighterlike targets (BQM-34A drones and QF-9Gs). The attacking aircraft locked on with their radars and had to assume proper attack speed and range before firing. Of 2 missiles fired at BQM-34As in 45-deg turns at 40,000 ft, 1 missed by about 200 ft, and 1 caused only minor damage. Of 9 fired at QF-9G drones (ex-fighters) in 3-G turns at 15,000–20,000 ft, 2 failed for undetermined reasons and 7 failed to guide. All had been fired in the heart of the calculated envelope, at angles-off of 5–10 deg and at slant ranges of 3000–5000 ft. In 5 cases, the missile guided initially but failed to follow the target through the turn. One missile did succeed in killing a QF-9G at 5000 ft. Worst of all, it was extremely difficult for pilots to keep their airplanes within the heart of the Sidewinder envelope as defined by these unsuccessful tests.

By 1964 some of these problems were already being overcome in the AIM-9D (which had been designed well before the problems were known): it was much more maneuverable, and its seeker operated in a much less cluttered part of the IR spectrum. AIM-9B tactics also improved. During 1 period in 1966, for example, the air force fired 21 missiles, achieving only 5 hits. However, of the others, 6 had been fired without any tone in the earphones (in effect, jettisoned), 4 were out of range, 1 was launched at 6 Gs, 1 was too close to arm its fuze, and 4 apparently never armed because they were too close or overtook the target too rapidly. In a 1967 operation, of 12 launched, 7 guided, and all either killed or probably killed their targets. Of the other 5, 2 were fired at a target that disappeared into clouds before they could hit, and 3 were fired to break up an attack on a friendly fighter (i.e., to force evasive action).

The net effect of improvements, in versions such as -9D and -9E, was to turn the relatively sluggish Sidewinder into a snapshot dogfight weapon. That was partly because it could be fired and forgotten, whereas the alternative, Sparrow, requires the launching airplane to continue to illuminate the target. Partly, too, because no illumination is needed, a properly designed version of Sidewinder can follow a target through convoluted maneuvers.

In all, 452 Sidewinders were fired in combat in Vietnam, for a net single-shot kill probability (as published in 1980) of 0.18. In 1980, using AIM-9L, the U.S. Navy expected a single-shot kill probability of 0.50, the U.S. Air Force 0.285. That year OSD estimated that Sidewinder kill probability was 0.15 against a low-flying fighter and 0.30 against a high flier; comparable estimated figures against a bomber were 0.20 and 0.40. Recent experience suggests that these are rather conservative estimates.

AIM-9C (Sidewinder IB) was the radar semiactive-homing (in X-band) version, suitable for head-on attacks; it could also home on jammers. Many were later converted to Sidearm antiradar missiles. This missile was developed in parallel with AIM-9D, with which it shared a common airframe, a 25-lb continuous-rod warhead (radius 17 ft, using PBXN-3 rather than HBX-3 explosive), and a more powerful (14,200 vs. 8450 lb-sec specific impulse) longer-burning (5 rather than 2 sec) motor, with a correspondingly longer-burning gas generator (60 vs. 20 sec; 38 sec for the -9C), which increased range to 11.5 nm. AIM-9C performance was slightly worse than that of -9D because it was slightly heavier, had greater drag (because of its hemispherical radome), and had shorter guidance time. It had a slightly greater minimum altitude. Maximum seeker look angle was 55 deg.

AIM-9D (Sidewinder IC) was redesigned, the lead-sulphide seeker being nitrogen-cooled. It had a new magnesium-fluoride (instead of quartz) dome, better streamlined (3-in rather than 5-in hemisphere). It had a 2.5-deg angle of view, 40-deg maximum look angle, and a 125-Hz reticle; and it tracked at 12 deg/sec. The smaller field reduced background noise since the target necessarily occupied more of the total field. Compared to -9B, -9D could be used at greater angles to the target's tail. This capability was exploited by providing broader-chord fins for better maneuverability. This version was credited with limited head-on capability. About 1000 AIM-9Ds were made for the U.S. Navy. AIM-9D was, in effect, the first second-generation Sidewinder.

Test results for AIM-9B vs. AIM-9C (1963) showed:

Aspect	Fighter (Mach)	Target (Mach)	Altitude of Both (ft)	Range (ft)	
				-9B	-9D
Tail	0.8	0.8	500	5400	14,000
Tail	0.8	0.8	20,000	10,500	22,000*
Tail	0.8	0.8	40,000	19,700	40,000*
Tail	1.0	1.0	50,000	23,100	47,800*
Nose	1.12	1.68	Fighter: 40,000 Target: 53,000	no cap	53,000*
Max Altitude for firing				67,000	85,200

The asterisks indicate figures that were expected to be bettered in later firings. Maximum range increased at higher alti-

tude, where the target was much brighter against less background radiation.

Both AIM-9C and -9D entered service in 1965, and several thousand were made for the U.S. Navy and for Britain.

AIM-9E was a modified -9B for the U.S. Air Force, under a Low-Altitude Performance (LAP) program suggested by the manufacturer, Philco, in 1965. Improvements included a new thermo-electrically cooled (Peltier cycle) lead-sulphide seeker and revised electronics and wiring. About 5000 missiles were converted to this type, about 1967. The detector had a 40-deg look angle, a 100-Hz reticle, 16.5-deg/sec tracking, and a reduced solar dead zone. Cooling increased sensitivity, particularly against high clutter at low altitude; the wider seeker angle improved attack, and faster tracking made for better low-altitude performance. The European Sidewinder consortium produced the parallel FGW Mod 2, the lead-sulphide detector being carbon-dioxide cooled; the solar dead zone was reduced to 5 deg. Silicon replaced the glass radome. AIM-9B and -9E missiles were further updated to -9J standard (see below). AIM-9E2 has a reduced-smoke motor. AAM-1 is a Japanese version, somewhat smaller and lighter than the U.S. version (102.4 in long, 154.3 lb vs. 118.1 in, 164 lb).

AIM-9F was a new-build -9B (FWG 2) manufactured by the European consortium (BGT), with a more sensitive lead-sulphide seeker and a more powerful motor. Sweden uses this weapon under the designation RB 24.

AIM-9G was the U.S. Navy equivalent to -9E, developed under the SEAM (Sidewinder Expanded Acquisition Mode) program, permitting off-boresight target acquisition and lock-on. The seeker was slaved to the fighter's radar as it scanned, so the missile could acquire a target within the maximum look angle (or the maximum look angle of the radar, whichever was smaller). Maximum range is reportedly 19,360 yd. Dimensions: 5 × 113 in, span 24.8 in, weight 191 lb. Production of this version ended in 1970.

AIM-9H replaced -9G, and nearly 5000 were made. This version is credited with limited all-weather capability, i.e., with the ability to continue to attack a target through haze and light cloud cover. The seeker is described as forward-biased, which probably means that proportional navigation (using a gyro as reference) has replaced the earlier pursuit navigation. Forward-biasing will cause the missile to hit an airplane near its cockpit, where the target is most vulnerable. It will also greatly reduce the value of any decoy projected aft from an airplane. This version introduced solid-state electronics in the seeker, and it has a faster-tracking seeker (20 deg/sec) and double-delta wings, the latter for better maneuverability. AIM-9H was the last purely naval version of the missile. Production of 7720 AIM-9H began in 1972, the missile entering service in 1973. Weight is 186 lb.

AIM-9J was a -9B or -9E rebuilt for the air force, with partially solid state electronics and double-delta wings with more powerful actuators, plus a longer-burning gas generator (for flights lasting up to 40 sec, but not the 60 sec of the -9D and its descendants). Maximum range is reported as 15,850 yd. Overall range is sacrificed for high acceleration to deal with fast targets. About 6700 were delivered by Ford Aerospace, about 1970. AIM-9J1 is a new-build missile, -9J2 a converted -9B, and -9J3 a product-improved version. Dimensions: 5 × 120.9 in, span 22 in, weight 172 lb.

AIM-9JUL1 is an upgraded AIM-9J/N/P developed by Bodenseewerk, to achieve performance and reliability comparable to that of AIM-9L at a significantly lower price. Highly reliable AIM-9L subassemblies such as the all-aspect seeker, the guidance electronics, and the coolant-bottle section are combined with the control-servo section of the AIM-9J/N/P to form a new guidance and control unit, which is attached to the unchanged body of the AIM-9J/N/P missile. BGT claims that AIM-9JUL1's performance matches that of AIM-9L, except for minor limitations due to the earlier missile's smaller control-servo torque and slightly lower thrust. The company also claims that the frontal acquisition range of the all-aspect seeker and the thrust profile of its rocket motor provide it with surface-to-air capa-

bility comparable to that of AIM-9L/SHORAD. As of the summer of 1990, JULI was still a private-venture proposal, BGT promising first deliveries 26 months after contract award (missiles would be delivered for modification 18 months after contract award).

AIM-9K was an alternative to AIM-9L developed by China Lake but not produced.

AIM-9L is described as a third-generation missile (-9B was the first, -9D the second) developed on a joint-service basis. It was based on AIM-9H but was effective at all aspects, capable of engaging violently maneuvering targets, and effective against fast aircraft even at medium range. It has a new active-laser proximity fuze (DSU-21) consisting of 8 GaAs laser diodes plus 8 photodiode receivers. The warhead is a new 20.8-lb annular blast-fragmentation type, using preformed rod fragments.

A magnesium-fluoride window covers an argon-cooled indium-antimonide detector that operates in 2 colors (i.e., at both long and short wavelengths). The new seeker head was originally developed by Bodensee (the European Sidewinder manufacturer) for the abortive German Viper short-range air-to-air missile. Unlike previous missiles, this one uses a fixed reticule, with a moving tilted mirror (rotating Cassegrain system) performing a conical scan modulated in both frequency and amplitude (presumably a variant of a rosette scan). This arrangement improves sensitivity and tracking stability, and it also allows for later incorporation of a more elaborate detector, e.g., imaging infrared (since the relation between reticule and detector is now fixed). There is a new guidance and control group (DSQ-29). The missile has an internal coolant tank, so it can be carried by air force aircraft (U.S. naval aircraft have coolant bottles in their missile launch rails).

There were several other improvements to the seeker electronics. Because the seeker scans conically, it does not see a target dead ahead; normally, then, the pilot would hear no tone at all when the missile was perfectly boresighted. An ingenious audio enhancement bridges this dead zone so that the pilot can register when the optical axis of the missile is precisely aligned with the target. The missile must be limited in initial maneuverability since otherwise there is a chance that it will acquire the launching airplane. In this version the seeker is partly caged for the initial phase of its flight; it can make full use of increased maneuverability later on. Instantaneous seeker FOV is reduced to decrease the effect of background noise. Since that also reduces the probability of target acquisition, a scan mode is provided to increase the missile's effective FOV. The radar-slaved SEAM mode also improves the chance of initially acquiring a target.

In 1980 it was reported that a combination of modified signal processing and a new seeker reticule would improve background discrimination by a factor of 3, and that new tracking software would greatly improve performance against glinting targets, i.e., against targets visible only by the reflection of sunlight on their surfaces. This program began in 1977. It is sometimes denoted ALASCA (all-aspect attack capability). AIM-9L was the version used so successfully by the British during the Falklands War; 100 were supplied, and they shot down at least 25 aircraft. In Swedish service this missile is designated RB 74.

AIM-9L/I is a modified AIM-9L, developed by BGT. One of 4 electronic modules is changed, for better countermeasures resistance, comparable to or better than that of AIM-9M. AIM-9L/I was tested for the first time at China Lake in the summer of 1990, achieving 3 successes out of 3 shots.

AIM-9M is the current U.S. production version, with improved countermeasures resistance and clutter rejection. It incorporates a Hughes closed-cycle cooler. Production began in 1981. Weight is 189.6 lb. The new motor is smokeless.

AIM-9N is a rebuilt -9J (formerly designated -9J1) intended for foreign military sales. Three of the major circuit boards of the earlier version were redesigned. About 7000 of these missiles were made.

AIM-9P is an export version of the current -9M, either a rebuilt AIM-9B/E/J or new production. AIM-9P1 introduced a

laser proximity fuze in place of the earlier IR fuze. -9P2 has a reduced smoke motor. -9P3 has an IR fuze, a reduced-smoke motor, and a stronger warhead and guidance/control section; this version employs a new explosive that is less sensitive to high temperatures. -9P4 has increased IR acquisition and guidance capability and an optimized fuze. Weight is 170 lb.

AIM-9R is the next-generation version, a product-improved -9M. Ford was awarded the contract in April 1987, and the missile should enter service in 1992. -9R has a new IIR detector, using CCDs that do not have to be cooled. The array detector should increase range and simplify support. Weight is 193 lb, and range is reportedly 21,125 yd. Work on this version, originally called AIM-9M(PIP), began in 1986. Current navy plans call for conversion of 5000 AIM-9M to -9R standards. The U.S. Air Force is testing a new control system developed by Elbit (of Israel) to provide off-bore-sight capability. This control system slaves the seeker head to the aircraft radar or to a helmet sight. Tests were completed in March 1988.

AIM-9R was first fired in April 1990. The U.S. Air Force claims that it is too expensive and does not meet requirements. It has proposed an alternative AIM-9M Plus; but as of mid-1990, DoD was trying to determine whether this duplication of effort was justified.

AGM-87A (Focus) was a slightly modified Sidewinder intended for night attacks against visible IR emitters such as truck headlights; it was quite successful during 1969-70.

In FY85 flyaway unit cost was \$55,000. Recent procurement by the navy: FY84, 350; FY85, 1000; FY86, 2120; FY87, 627; FY88, 288; none in FY89. Total production run, approximately: AIM-9B, 80,000; -9C, 2000; -9D, 12,000; -9E, 5000; -9G, 2120; -9H, 7700; -9J, 10,000; -9L/M about 14,950. Reportedly, it would take about 4 months and \$18 million to triple the current production rate under mobilization conditions.

AIM-9L is manufactured in an improved form by a European consortium (West Germany, Norway, Italy, and Great Britain) headed by BGT, which made earlier forms of the missile; in addition, Mitsubishi has been manufacturing AIM-9L under license since 1981. Reportedly, the West German army has evaluated AIM-9L (with a modified microchip) as a short-range surface-to-air missile, and 5 test firings were conducted in August 1986. Although no naval application was reported, such a missile might serve as an emergency alternative to RAM.

The U.S. Navy uses Sidewinder only in an air-to-air version. However, the Taiwan navy uses a surface-launched version, Sea Chapparral, a seagoing version of an army missile, work on which began in 1959. The U.S. Navy did mount 9 Chapparrals on board *Gearing*-class destroyers in 1972 (they were removed in 1973) as a form of close-in defense during the Vietnam War. Chapparral had been tested on board a large amphibious ship in 1963, and it was proposed (as the 10,000-lb Seawinder) in 1967-68 as an interim defense against Styx missiles. At that time, Seawinder was rejected in favor of longer-range offensive missiles, particularly Standard Active and Standard ARM, which could be used to destroy the Styx platforms before they came within range. The Sea Chapparral mounting was never standardized by the U.S. Navy, and details are not available. The mounting can be controlled either remotely (using a camera in the mounting) or locally. It arms Taiwanese (ROC) destroyers and frigates, as well as the LSD *Cheng Hai* and the new replenishment ship *Wu-Yi*.

Sea Chapparral is fired from a 4-rnd turret, with 8 more missiles stowed for ready use. The operator locks onto the target using an optical sight, and the system can be improved by adding a FLIR; targets can also be designated by other ship sensors. Range is about 2.2 nm.

The missile is MIM-72; the first version, MIM-72A, was equivalent to AIM-9D. The first production missiles were delivered in 1969, and the system entered combat in the 1973 Middle East War. MIM-72B has a more powerful warhead and a better seeker and fuze. MIM-72C, developed in 1970-74, has an all-aspect seeker, a larger warhead, and a radar (doppler) proximity fuze. The addition of a 2-color rosette-scan seeker (as in

AIM-9L) and a smokeless motor resulted in MIM-72C/R (rebuilt MIM-72C) and the production MIM-72F; -72D and -72E were test versions for the improved seeker and a new directional-doppler proximity fuze. The current version is MIM-72G, with a combination of 2-color rosette-scan seeker and scanning spatial discrimination, using digital programmable electronics. The seeker can be reprogrammed (to adjust to different countermeasures) up to the moment of launch. Reportedly, the Taiwanese versions are MIM-72C, -72C/R, and -72F. Probably, these weapons will ultimately be supplanted by an indigenously developed air-to-air missile, broadly comparable to AIM-9L/M, Tien Chien (Sky Sword) I.

Ford had proposed a Chapparral II with a new reduced-drag airframe, tail rather than nose control surfaces, and a new motor, for an effective range increase to 11,000 yd. The new missile would also have a new dual-mode (IR and antiradar) homing system.

Sidewinder is to be succeeded by a British-developed ASRAAM (AIM-132). However, ASRAAM development has been protracted. Hence the decision to place AIM-9R in production in 1990, as an interim weapon.

A new Sidewinder seeker was displayed at the Association of Old Crows (EW association) meeting at Boston in September 1990. It incorporates a new AMT massively parallel computer (described in the Addendum), which is powerful enough for multispectral image processing. At least as displayed at the show, the seeker employs a large-diameter gimballed Cassegrain mirror (i.e., with a sensor at its center and a small mirror forward of it to reflect the image from the large mirror back into the sensor). The modified Sidewinder was described as robust against current countermeasures (i.e., against flares and IR suppressors, as well as flashing lamps), satisfactory for day/night operation, and effective against helicopters (and not against their exhaust plumes). It was also described as low cost and low risk. The implication was that this was a staring array using processing so powerful that it could distinguish the relatively cool skin of a helicopter against the cooler sky or even the ground. The logical suggestion is that, at least in clear weather, this sort of seeker can easily distinguish stealthy aircraft and missiles since they cannot cool themselves below ambient temperatures.

Next to the Sidewinder front end was another missile nose marked SRM (presumably Short-Range Missile), with an acutely pointed (rather than rounded) and faceted (6-sided) nose, carrying a larger-diameter mirror virtually filling its diameter (which was about that of the Sidewinder). SRM is presumably a formerly black Sidewinder successor project. It will be faster than Sidewinder (hence the need for the pointed nose). The facets are presumably needed to minimize optical distortion.

These missiles are part of Martin Marietta's attempt to win a contract to develop the next-generation air-to-air missile, either as a new version of Sidewinder to succeed AIM-7M or as a new missile altogether. Because the company had no previous experience of similar weapons, it felt compelled to produce some prototype hardware. As of September 1990 the next-generation requirement had not yet been funded, and other companies were also interested in the potential for such a program, which the air force would lead. They, too, are using imaging IR seekers associated with massive computing power.

◆ Sparrow and Sea Sparrow (AIM-7/RIM-7)

Dimensions: 8.03 × 141.5 in (wing 24.65 in folded, 40.6 in open; tail span 24.3 in) **Weight:** 500 lb

Warhead: 67-lb continuous-rod (17.9-lb DATB explosive) in 7E version; 86-lb continuous-rod WEU-3/B in AIM-7M

Propulsion: rocket boost-glide **Speed:** Mach 4.0

Range: depends on guidance radar (24–28 nm air-to-air for AIM-7M). Sea Sparrow's range (7E version) was 12,000 yd (1500 minimum); maximum altitude was 18,000 ft. Maximum speed was 1600–1800 ft/sec, and warm-up/reaction time was 8 sec/9–16 sec. These data are now obsolete, but they give some idea of the system's performance. The current NATO Sea Sparrow range is reported to be 8–14 nm (16,000–28,000 yd).

Sparrows and a Sidewinder carried under an F-14. (U.S. Navy)

Sea Sparrow being loaded into 1 cell of its launcher. Only the Canadian version of Sea Sparrow (on board Tribal-class destroyers) is power-loaded; the NATO version and the earlier Basic Point-Defense Missile System both use hand-loaded 8-cell launchers. (U.S. Navy)

Sparrow Configuration Evolution

Raytheon's proposals for advanced Sparrows, 1988. (Raytheon)

Data apply to RIM-7M; AIM-7M has longer wings.

Sparrow (AIM-7) is the current standard U.S. radar-guided air-to-air missile, supplemented by Phoenix (AIM-54) only on F-14 fighters. Sparrow arms F/A-18 Hornets. Because it is semiactively guided, Sparrow requires a large illuminating radar on the fighter, and the firing airplane must illuminate the target all the way from launch to kill. For these reasons Sparrow cannot be carried by lighter naval aircraft such as the Harrier/Sea Harrier and the A-6 Intruder; Sparrow also cannot be used effec-

tively against saturation raids. In theory, AMRAAM (AIM-120) solves both problems, by combining a data link and an active seeker. However, AMRAAM is quite expensive; and Raytheon, which manufactures Sparrow, believes that AMRAAM will continue in development for some time.

Sparrow is the West's primary, current, beyond-visual-range missile. In Vietnam this capability was something of an embarrassment since without very reliable IFF a long-range missile would inevitably destroy numerous friendly aircraft (which were, after all, the great majority of all aircraft in the area). Hence the development of the long-range AXX-1 television described in this section.

The overall Sparrow single-shot kill probability in Vietnam was only 9%. By 1980, however, the U.S. Navy estimated Sparrow's single-shot kill probability as 35%, and the corresponding air force estimate was 28.5%. OSD estimated 15% against a fighter at low altitude, 35% against a fighter at high altitude; corresponding figures against a bomber were 20% and 56%. Figures from recent combat, e.g., in the Israeli air force, have not been published.

Sparrow was conceived as a radar beam-riding guided version of the 5-in high-velocity aircraft rocket, Hot Shot (by analogy with a parallel British project, Long Shot); the guidance system drew on work being done on contemporary surface-to-air weapons (the now-extinct Talos and Terrier). In May 1946 Sperry was asked to submit a proposal for a weapon with a maximum range of not less than 2000 yd, and a minimum range of not more than 1000 ft, fast enough to attack a Mach 1 target. The original 5-in airframe was too small, and Douglas was asked to design the 8-in airframe ultimately adopted. The contract was awarded in May 1947, and the weapon named Sparrow. The first target was intercepted on 3 December 1952, production already having begun because the bomber threat to carriers was considered so urgent. The Sparrow I (AIM-7A) beam-rider entered fleet service in 1956. Although beam-riding was unacceptably inefficient, about 2000 of these missiles were manufactured before production ended in 1962.

Sparrow II (AIM-7B) was an abortive active-radar version, ultimately intended to arm the Canadian Arrow (CF-105) interceptor. It was much too far ahead of its time and died with the airplane project.

Sparrow III (AIM-7C) was the successful version, using CW semiactive homing similar to that applied to Terrier and Tartar (the forerunners of the Standard Missile ER and MR versions). Deliveries began in January 1958. About 2000 were made.

AIM-7D, the first version to be used in combat, could be fired at supersonic speeds. It could home from the forward hemisphere, i.e., could accept very high closing rates, and it could also home on a jammer. Compared to AIM-7C, it had a storable liquid-fuel motor (specific impulse 15,000 lb-sec over 1.9 sec) instead of the earlier solid-fuel type, increasing effective range by about a third and ceiling by 10%, to 30,000 ft. The warhead was a 65-lb continuous rod (circle radius was 56 ft, and lethal range was 125 ft).

Although the notes on guidance that follow apply specifically to AIM-7D and -7E, they still apply to other Sparrows and to similar semiactively guided missiles.

This missile (and its successors) had receivers on its tail fins, so it could measure relative target velocity by comparing this reference signal with the signal reflected from the target. When the missile was fired, the speed (doppler) gate swept a frequency band until it detected the appropriate preset target doppler. The gate within which the target doppler had to be could be set wide or narrow, the narrow setting being much better for rejecting clutter such as chaff. In the narrow setting, the gate swept 5 kHz to either side of the preset frequency, 1 kHz corresponding to a speed of about 30 kt (so that the total sweep corresponded to 150 kt). The wide speed was 6–138 kHz (150–4100 kt), corresponding to a total lack of presetting information. Aside from the likelihood that the missile would lock on to the wrong target, the sweep over the wide gate took so long that the missile might fail to lock on altogether.

AIM-7D used proportional navigation, the autopilot obtaining both relative target speed (via doppler) and line-of-sight rate. Since flight characteristics would change with altitude, the control system had a set of preset altitude bands. The missile could be fired in 1 of 2 modes, full-system and bore-sight (snap-shot). In the full-system mode, the computer of the firing fighter provided the narrow-gate doppler and the initial lead angle. Bore-sight was intended for use when the target was so close that radar could not be locked on. The radar is caged to the boresight axis of the airplane, so the target will be illuminated when tracked within the 50 mil optical sight. There is no lead-angle indication, and the missile must be fired with a wide gate, since the fighter FCS is not engaged.

Many AIM-7s were fired in bore-sight mode in Vietnam, and few worked properly, given the limitations of the wide doppler gate. A third method, "manual boresight," was therefore invented. The missile is locked onto an imaginary target, and a closing speed manually set; the typical value for a tail chase was 150 kt. Although simple in theory, manual boresighting was difficult in practice because all of the interlocks designed for use in the full-system mode had to be cut out. A joint air force/navy task force on AIM-7 effectiveness recommended that aircraft carrying the missile be provided with a Target Aspect Switch providing 4 different closing-attack inputs, depending on the situation. For a head-on attack, the closing rate would be the fighter's speed plus 450 kt; for the forward quarter, head on plus 240 kt; for a tail chase, fighter's speed minus 240 kt; and for zero closing speed, zero input.

Tests in 1965 showed that the Target Aspect Switch provided Sparrow with a useful capability against low-altitude and maneuvering targets, although it was still difficult for the pilot to estimate the proper firing range. In the 1965 tests, manual boresighting made for about 50% successes. If the missile could be fired in full-system mode, it could attack a nonmaneuvering target at altitudes as low as 5000 ft. Properly used, it could also be extremely effective against maneuvering targets, demonstrating (in 1965 tests) a success rate of 41% (55% when adjusted for failures due to aircraft and missile malfunction) against subsonic maneuvering targets.

Reality in Vietnam was much less happy. For example, during a short period in 1966, 13 AIM-7D were fired. One hit. Four were deliberately fired out of the launch envelope to break up an enemy attack, 4 were fired in the allowable launch envelope but failed to guide, 3 motors failed to fire, and in 1 case the guiding radar broke lock after the missile had been launched. About 7 months later, 18 AIM-7E missiles were fired during 1 operation (BOLO, 2 January 1967); 2 more failed to launch altogether. Two more missiles were lost because the firing airplane's guiding radar broke lock after launch. However, of the remaining 16, only 8 guided properly, making 4 confirmed kills and 1 probable.

These figures meant that reliability, rather than some conceptual flaw in the missile, was the major issue, and therefore that Sparrow would become extremely effective as electronic technology improved. Discounting missile failures due to unreliability, the BOLO result was a kill rate of at least 50% among missiles for which the fire-control radar functioned properly.

Because AIM-7D was a boost-glide missile, its effective range depended very much on the speed of the launching aircraft (which was, in effect, its first stage).

About 7500 were made. Dimensions were 8 × 144 in (weight 398 lb, wingspan 40 in, tail span 32 in).

The next version, AIM-7E, was produced between 1963 and June 1973; it was the basis of most other Sparrow variants. About 25,000 were made. AIM-7E was widely used in Vietnam and hampered there because its maneuverability was limited by low terminal energy. It had the same dimensions as -7D but weighed 435 lb, most of the extra weight being its more powerful motor.

The new pure-sustainer (total impulse 22,100 lb-sec, burn time 2.9 sec) rocket motor added about 75% to the missile's

range. In 1963 the manufacturer, Raytheon, credited -7E with an effective intercept range (against a 5-m² target at 50,000 ft) of 16 nm, assuming that the launching aircraft was flying at Mach 2, with a time of flight of 40 sec. In 1968 the U.S. Air Force credited the missile with a maximum range, in a frontal attack against a fighter, of 13 nm (3 nm in a stern chase). Typical minimum ranges were 5000 ft for a stern attack, 12,000 ft head-on. The most important limitations were fuze-arming and time to make guidance corrections; another was the strength of the illuminating radar.

The other main improvements were increased seeker range, improved speed (doppler) gate circuitry for low closing and opening range rates, and improved ECCM.

AIM-7E2 (and the related RIM-7H, the first Sea Sparrow) was a modified and more reliable version introduced in 1969. It had a "dogfight" guidance mode (faster tracking and stronger flight-control responses) and an improved fuze (with shorter arming time, for shorter minimum range), and it could fly at higher altitudes. Minimum range was reduced, the guidance system locking up more quickly after launch. The missile could tolerate a higher G-load. AIM-7E3 had an improved fuzing circuit and was more reliable. AIM-7E4 was protected against the "spillover" radiation of powerful fighter radars.

Raytheon proposed an "Advanced Sparrow III" as early as 1963 as an alternative to Phoenix; it would have a programmed fly-out to permit launch at the aerodynamic launch limit, which would itself be increased by using a new dual-thrust (boost-sustain) motor, burning for 3.5 sec (total impulse 30,800 lb-sec, total weight 200 lb compared to 156 lb for -7E). The missile could fly for as long as 75 sec, and it could reach 52 nm; more typically, it would double -7E's range, to about 30 nm. As in Aegis, effective guidance range depends in large part on the point at which the missile requires usable amounts of radar energy reflected from the target. A missile that can fly a considerable distance before requiring this illumination energy can guide onto a more distant target, using the same illuminating radar. Raytheon did not propose any kind of mid-course update, so this guidance mode presupposed a relatively sedate target.

The other new features proposed at this time were more compact electronics, freeing space forward of the wings for a heavier warhead (90 lb) and for the enlarged motor. Advanced Sparrow would have been compatible with pulse-Doppler, rather than CW, radar.

The main Advanced Sparrow capability, much greater range against a bomber, was not very attractive during Vietnam. It was revived later, and development of the new AIM-7F began officially in January 1972. It incorporated the new motor, and range was 24 nm using the Phantom radar (38 nm using the more powerful radar in the F-14); the proposed fly-out mode was abandoned. A new seeker was considered more effective against low fliers and multiple targets, and the new motor (Mk 58 rather than Mk 52) provided more energy for snap-up shots. AIM-7F also incorporated the new heavy warhead (Mk 71 rather than Mk 38) that had been proposed in 1963. The new guidance electronics were solid-state units in replaceable modules, for easier maintenance and better reliability.

The guidance technique was changed to adapt the missile to the new generation of pulse-Doppler radars. AIM-7F measures the range to the target by comparing the FM signal received on its rear (reference) antennas with the FM signal reflected from the target. The frequency difference is proportional to target range (this technique is analogous to the pulse-doppler radar-ranging technique described in the Prefatory Notes on radar). The missile receives target range from the fighter's fire-control radar, and it updates range by calculating target velocity (doppler). A range gate is used to reject countermeasures. AIM-7F was approved for production on 1 October 1974, the first production award (to Raytheon) following on 31 October 1975; the projected requirement was 6864 for the navy and 5415 for the air force.

AIM-7G had a new seeker but was only a prototype (1970).

The -7H designation was reserved for Sea Sparrow (see below), and there appear to have been no -7J, -7K, or -7L versions.

Instead, the next version was designated AIM-7M, the M standing for an inverse monopulse seeker, the principal improvement in the new missile (for better resistance to countermeasures). This version also has an active (presumably laser, rather than radar) fuze, a missile-borne digital computer, and an autopilot. The effect of the autopilot is to allow the missile to fly a considerable distance without requiring illumination. Thus missiles can be fired at several different targets in sequence, illumination being used only for mid-course and terminal homing. The autopilot permits the missiles to fly an energy-efficient trajectory. The combination of proportional navigation with a preset autopilot flies the missile in such a way that it almost never points directly at the target. The antenna points to one side. In theory, therefore, there is space alongside for an IR seeker, an option not incorporated in -7M missiles, but tested recently. Although in theory the autopilot allows for intermittent command guidance, there is no provision for a data link. Full-scale production of AIM-7M was approved on 12 December 1982, the first missile having been test-fired in April 1980.

In 1985 the U.S. Navy reportedly proposed a next-generation Sparrow, AIM-7X, as an alternative to AMRAAM (AIM-120A). In 1987 Raytheon won a \$19.6 million contract for this product-improved version, now redesignated AIM-7P. The new version incorporates current low-altitude fuzing modifications and has new guidance electronics (using VHSIC technology) capable of accepting mid-course guidance commands (with software modifications).

Production: AIM-7A, about 2000; -7B, 100; -7C, 2000; -7D, 7500; -7E, 25,000; -7F, 5000. In March 1987 the reported requirement for these missiles was 7988 for the navy and 6321 for the air force. Recent navy procurement: FY84, 695; FY85, 1671; FY86, 1948; FY87, 1716. None were requested for FY88, but Congress directed that the navy buy 600 because of delays in the designated successor program, AMRAAM. The navy's FY89 program included 450 Sparrows. The navy also plans to upgrade 4000 AIM-7F to -7M standards. It was reported in 1987 that the maximum production rate from 2 sources is 250 missiles per month. Unit cost (FY83) was \$198,209.

Sparrow has been very widely exported, and it is license-built by Selenia and by Mitsubishi. The Selenia Aspidé (see above under SAMs) uses much the same airframe but with different internal components, both for air-to-air and for surface-to-air use. The British Sky Flash, which has also been adopted by Sweden, is a modified Sparrow.

Sky Flash is a modified Sparrow (AIM-7E). British Aerospace has been marketing a proposed X/K-band active version since 1985, originally with a Marconi seeker. The current seeker contractor is Thomson-CSF; this seeker may be similar to, or identical to, seekers in the active version of Aspidé and also in the surface-to-air ASTER missile. The missile is being offered to countries that will not be permitted to buy AMRAAM; British Aerospace claims that it can be in service as early as 1992.

RIM-7, Sea Sparrow, is a ship-launched self-defense variant, the current version being RIM-7M. It is used in 3 major systems: the Basic Point-Defense Missile System (BPDMS), which uses the Mk 115 FCS and is being replaced by Phalanx guns (replacement of all 72 was announced 1981, to be completed by the end of FY88, but this target has not been met); the NATO Sea Sparrow System (Mk 91 director); and some examples of the Italian Albatros system (though most such systems fire the Italian Aspidé missile). BPDMS was developed from 1963 on to fire a folding-fin version of AIM-7E designated RIM-7H; it was first tested in May and June 1965. An alternative RIM-7F was derived from the AIM-7F air-to-air missile. Modifications consisted of rapid run-up, folding wings, and clipped tail fins. All versions of BPDMS were considered deficient against low-flying attackers.

NATO Sea Sparrow (the Improved Point-Defense Missile Sys-

tem) uses the same missile but a very different overall combat system. The director is automatically trained, on command from CIC. The NATO Sea Sparrow program was reportedly inspired by the sinking of the Israeli destroyer *Eilat* (the first combat casualty caused by a surface-to-surface guided missile) in 1967. Later that year a NATO Project Group prepared an MoU; it was signed by Denmark, Italy, Norway, and the United States. Belgium and the Netherlands joined the consortium in 1970, West Germany in 1977, and Canada and Greece in 1982. Raytheon was awarded the prime contract in September 1969. A production contract followed in August 1973.

An 8-cell box launcher (Mk 29) with frangible panels at the ends of each cell, was developed; it replaces the modified AS-ROC launcher of the U.S. BPDMS system. Raytheon, which manufactured the air-to-air weapon, was awarded the prime development contract in September 1969. The other development firms were Terma Electronisk of Denmark (microwave receiver), Selenia of Italy (firing officer's console/display module), and Kongsberg Vapenfabrikk of Norway (director controller, director pedestal, and computer). The system was first tested on board the frigate *Downes*, a second model going on board the Norwegian frigate *Bergen*; and all evaluation was completed by the end of April 1973. The first production systems were delivered in 1975. A full NATO Sea Sparrow system employs 1 or 2 Mk 91 directors. Typically the 8-cell launcher is manually reloaded. At this writing (1988) a standard modification is in train to fill 2 of the 8 cells with RAM point-defense missiles.

RIM-7H-1, the initial NATO Sea Sparrow missile, is AIM-7E-1 with a rapid run-up (RRU) modification, folding wings, and clipped fins. RIM-7H-2 is equivalent to AIM-7E-2, with RRU, folding wings, and clipped fins. RIM-7H-5 is RIM-7H-2 with a point defense fuze fix.

NATO Sea Sparrow Block I uses the RIM-7H-5 missile (modified AIM-7E). Operational evaluation was completed in February 1974. Development and operational testing of the full Block I system was completed in December 1977, with full-scale development following from June 1978. Block II uses the RIM-7M monopulse missile, which was introduced into the system in 1978. A projected Sea Sparrow version of the AIM-7F was abandoned in favor of a version of the monopulse-guided AIM-7M. Some consideration was apparently given to developing a missile specifically for Sea Sparrow use, with a simpler seeker (CW only, since the shipboard radar illuminator is not pulse doppler) and, therefore, a simpler and less expensive radome, a new autopilot, and simpler and less expensive aerodynamic features. This project was also abandoned; RIM-7M is a modified AIM-7M. Modifications to the missile include fuzing better adapted to low-altitude clutter, the ability to discriminate between multiple targets in a stream attack, and a self-destruct feature to protect friendly ships onto which the missile may inadvertently lock. The missile is also capable of discriminating between different illuminators since a ship may have several directors, and several nearby ships may fire Sea Sparrows together, most likely by sensing coding in the illuminator signal.

Total system weight, including 8 RIM-7M missiles, is 28,648 lb (13,676 lb for the loaded launcher, 3431 for the director and its television camera).

The Sea Sparrow system is triggered by a main search radar, such as the U.S. TAS Mk 23 or SPS-65. The radar designates a target to the Mk 91 director. The director then scans and acquires the target, modulating emissions for ranging and angle tracking. If the target fades during track, the director coasts in range, bearing, and elevation until it reacquires. During the target-tracking process, the Sparrow's time of flight to the target is computed; and the operator is alerted if the target is engageable. Shortly before the target comes within range the launcher is automatically assigned to the appropriate radar director and aimed at the predicted intercept point. In automatic mode, a salvo is fired when the target becomes engageable. In semiautomatic mode, the operator issues a firing command. Typically the U.S. Navy operates its Sea Sparrows in semiautomatic

mode. European navies tend to use the automatic mode. This distinction reflects a difference in operating conditions. Except in wartime, when they would face submarine-launched missiles anywhere at sea, U.S. ships probably would not face air attack unless they approached hostile shores. European warships are almost always within range of potentially hostile air or missile attack.

RIM-7M differs from AIM-7M only in that the former's wings are folded and tail fins clipped, for launcher stowage. Wingspan is 40 in (25 in folded) and tail span is 24 in. In addition, the rocket motor is remotely armed. The warhead is a WAU-17/B blast-fragmentation type, chosen over the earlier continuous rods (WAU-10/B) to destroy a nearby target passing at very high speed.

The current (1988) Sea Sparrow is RIM-7M, which is adapted for vertical launching. This version has improved surface-to-surface capability, improved surface look-up capability, and improved performance and reliability. Vertical- and box-launched missiles are identical, apart from the additional jet-vane control (JVC) unit bolted onto the tail of the vertically launched weapon. Both have a new active fuze, which incorporates a target-range gate and a sea-range gate, the latter to keep the missile from detonating against the sea at low altitude. The jet-vane control unit incorporates an inertial strapdown navigation computer; it pitches the missile over onto a course toward the target. Missiles fired from vertical launchers begin to tip over 0.7 sec after launch and do not rise above 200 ft when fired against low-altitude targets. The missiles are fully tipped over by the time they are 250 ft from the ship.

Compared to the standard trainable-launcher version, the VLS version provides more ready missiles (against saturation attack), quick launch after target detection, reduced topside space and weight, and quick engagement of fast sea-skimmer or pop-up missiles.

Like AIM-7M, RIM-7M incorporates an autopilot and, thus, has the potential for multiple engagements if that autopilot is set at launch time. Since the missile can fly for a considerable time before needing to detect energy reflected from the target, Raytheon has proposed engaging multiple targets by floodlighting: using a broad-beam radar (e.g., 45-deg beam) to illuminate several incoming targets simultaneously, and using an engagement radar to compute autopilot settings. The floodlight would illuminate each target only weakly, but weak illumination might be enough if the missile does not need to pick up radiation until fairly close to the target. In this way a single search radar and a very simple floodlight might bridge the gap between the current single-target Sea Sparrow system and a much more sophisticated system meeting the NATO AAW requirements. This floodlighting system has not been tested, and presumably it was the one rejected when Raytheon was dropped from the NATO AAW System program. However, the company argues that any substantially more complex solution will be prohibitively expensive. The Raytheon illuminator has 8 apertures, each producing a 45×75 -deg beam, plus a zenith horn (60×60 -deg beam). The system transmits through 1 selected illuminator at a time, power being 2 kW average (gain 10 dB). The beams are so wide that no mechanical stabilization is needed. The full pattern covers the entire hemisphere, down to 15 deg below the horizon (to allow for rolling motion).

The floodlight technique is already operational in the army's Hawk missile, in a program called LASHE (Low-Altitude Simultaneous Hawk Engagement). In this case the illuminator has a beam broad in azimuth but relatively narrow in elevation. As of mid-1990, the Raytheon NAAWS proposal still incorporates the floodlight technique.

A version of Sea Sparrow using a Signaal FCS was developed independently for the Canadian *Iroquois*-class destroyers; that version employs launching rails that deploy from the sides of the ship.

A vertically launched Sea Sparrow prototype was tested at sea in 1981, and a formal NATO Sea Sparrow ORDALT issued in

1981. Canada decided to purchase the vertical-launch system for its "City"-class frigate in 1983, Raytheon receiving the contract the following year. The vertically launched RIM-7M was successfully tested at White Sands in 1985. Test launches included shots at simulated low-altitude targets, at mid-range and off-axis, the missiles avoiding the simulated ship's superstructure; there were also low-altitude short-range shots. The Royal Netherlands Navy bought this system for its M-class frigates in 1985, and Greece chose it for the new MEKO-200 frigate in 1988. Delivery of 6-launcher ship sets for Canada was completed in 1987, and production deliveries of 155 Canadian units was completed in 1988. A total of 256 missiles are on order for the Netherlands navy, as of 1988.

In 1988 the expected total production run of RIM-7M was 2950 missiles, and unit cost in FY85 was \$214,000.

In 1988 Raytheon announced a program for further Sparrow evolution, using the RIM-7M as a baseline. For improved aerodynamics against violently maneuvering targets, the missile was redesigned for tail control. With this modification, the missile can carry a larger rocket motor with increased thrust and can maintain its current vertical-launch capability. The missile's existing reprogrammable computer is adaptable to multimode guidance (semiautonomous mid-course, IR terminal, and anti-radar homing). This wingless Evolved Sea Sparrow (ESS) offers twice the maneuvering power of the winged missile. ESS would have a new autopilot, all-boost rocket motor, and tail controls. The forepart (seeker and warhead) would match RIM-7P (see below), but the after part would be necked out to 9-in diameter; total weight would be 245.1 kg (540 lb), and length would be 145.7 in [3.7 m]. Evolved Sea Sparrow could be in service by 1994. Raytheon claims that ESS will have 2 to 4 times the energy of the existing Sparrow and that ESS can easily be backfitted on board ships now equipped with NATO Sea Sparrow.

A further stretched version, the Long Ship-Defense Missile (LSDM), which Raytheon claims could be in service by 1998, would offer Mach-3 speed and twice the current range. ESS and LSDM would share common control and tail-fin (jet-vane) systems. The missile would receive mid-course guidance through the illuminator, whose signal would be modulated.

Raytheon proposes a 4-missile canister launcher for these weapons, each cell of which would be about 11 in across (total width 25 in).

The ESS/LSDM combination was Raytheon's candidate for the NATO Antiaircraft Warfare missile system. The company argues that this system may well be adopted when the alternative, more sophisticated, systems prove too expensive.

Meanwhile, RIM-7P is likely to be the next version of Sea Sparrow. Tests began in 1989, and production was approved in October 1990. The main changes from earlier versions are improved low-altitude performance, an advanced reprogrammable (VLSI) missile-borne computer, an up-link capacity, and the ability to accept delayed lock-on.

The higher-capacity computer is a major change, allowing the missile to execute a much greater variety of maneuvers, and also allowing for more fuzing options. Existing Sparrows fly an up-and-over trajectory, but RIM-7P can fly an offset path (the horizontal equivalent of up-and-over). For example, the missile can fly out in front of an approaching target. Beginning with the 7M version, the Sparrow flight path has varied with target type (e.g., sea skimmer, helicopter, surface ship, aircraft), but -7P has a richer repertoire.

The up-link provides the system with the potential for Aegis-like operation, if a ship is equipped with a suitable 3D radar. That should apply to a variety of foreign ships with radars such as the Dutch SMART. It also opens the possibility that the U.S. Navy will adopt RIM-7P as a shorter-range supplement to SM-2, 4 Sparrows occupying a single cell of the Mk 41 launcher (a capacity already tested as part of the NAAWS program).

Delayed lock-on was originally required to adapt the missile to vertical launch since the missile could not enter the guidance beam until it pitched over. Now all Sparrows can fly for a time before they must see energy reflected by the target. The set

delay is no longer fixed by the missile's trajectory requirement; instead it is determined on the basis of target trajectory. For example, the target may be outside the seeker angle when the missile is launched. A time delay also allows the missile to maneuver to intercept a maneuvering target, if the illuminator is initially masked.

Several component improvement programs are currently in progress. The navy's conventional munitions program includes work on a dual mode (RF/IR) fuze and fuzing against low observable (i.e., stealthy) targets. The 2 projects are closely related, and they were merged in FY88. Raytheon has been conducting a Sparrow low-altitude-fuze product-improvement program (PIP). The preliminary design review was conducted in January 1988, and the first development-test missiles were delivered in October 1988. There is also a Sparrow Missile Homing-Improvement Program; a seeker survey was conducted under the FY89 program.

RIM-7P was operationally evaluated in June 1990, and as of August, a production decision was expected by the end of the summer. The new version should be more effective against low fliers. Work is currently proceeding on the tail-controlled RIM-7R.

SHIPBOARD GUNS AND GUN SYSTEMS

The terms gun and mount are often used nearly interchangeably in this section. In a few cases, the same gun (barrel and breech mechanism) is used in different gun mountings, and the distinction is worthwhile. In most cases, however, a particular combination of gun tube and breech and loading mechanism is always associated with the same mounting, and no distinction is worth making. The term "mount" (or mounting) is generally taken to include the guns it carries, so that one describes a weapon as, say, a twin 40-mm mounting or a twin 40-mm gun.

CHINA

China continues to use a derivative of the Soviet 130-mm twin semiautomatic mount described in the Soviet section; the Soviet guns were used only on board "Kotlin"-class destroyers, now being discarded.

◆ ENG-2

Caliber: 100-mm/56 **Rate of Fire:** 25 rnds/min/barrel
Muzzle Velocity: 916 m/sec [3004 ft/sec]
Maximum Range: 22,500 m [24,600 yd] (maximum altitude, 15,000 m [49,000 ft])
Training Rate: 25 deg/sec (elevation 20 deg/sec)
Elevation/Depression: +85/-5 deg
Ammunition Capacity: 52 rnds ready-service
Weight: 34 tons

This new twin auto-loading 100-mm gun has supplanted the single 100-mm/56 in Chinese production. It arms Jianghu-II- and -III- and Jiangdong-class frigates and has been offered for export on board a projected frigate designation EF30. The mount is servo-controlled by a director. Traverse limits (left and right) 225 deg. Acceleration: 23 deg/sec²/in elevation, 20 deg/sec²/in traverse.

There has been some speculation that the Chinese would manufacture the French 100-mm Compact gun or a derivative, having bought 2 from France.

FRANCE

◆ 100-mm

Caliber: 3.9-in/55 (13.5-kg projectile)
Rate of Fire: 90 or 40 or 10 (selectable) rnds/min
Muzzle Velocity: 870 m/sec [2850 ft/sec]
Maximum Range: 17,500 m; maximum effective range 12,000 m for surface fire, 6,000 m for antiaircraft fire [19,100/13,100/6600 yd]
Training Rate: 50 deg/sec (elevation 32 deg/sec)
Elevation/Depression: +80/-15
Ammunition Capacity: 66 or 114 (ready-use)
Weight: 13,500 kg [29,750 lb]

Two 100-mm gun mounts on board the destroyer *Duguay-Trouin*, 1982. (L. Van Ginderen)

The 100-mm Compact mount, showing the ammunition fan feed up the side of the mount and the conveyor that elevates with the gun. (Creusot-Loire)

The 100-mm is the standard French dual-purpose gun mount; the larger 127-mm (5-in) gun formerly mounted on board cruisers and destroyers is no longer in service. In effect the 100-mm replaced both the 127-mm and the contemporary twin 57-mm anti-aircraft gun (see below for details of the surviving mounts) with a single weapon. This 100-mm gun fires a shell heavy enough for shore bombardment but light enough for the gun to achieve a rate of fire high enough for useful anti-aircraft work. 100-mm was the first French-designed fully automatic medium-caliber gun and follows an earlier (Model 1945) twin 100-mm weapon (mounted on the battleship *Jean Bart*). Development of

the 100-mm gun superseded work on a projected 105-mm/60 twin triaxially stabilized mount, which would have used surviving stocks of German ammunition.

Data refer to the export (Compact) version, used in the Portuguese, Saudi Arabian, and Malaysian navies; 2 copies were sold to China (PRC). Most have a 42-rnd magazine; those for Malaysia had 90-rnd magazines. In addition, 18 rds are carried in an intermediate magazine next to the gun (see below for an explanation of these figures).

The Compact mount is a lighter-weight (7.5 tons saved) version of the standard French 100-mm Model 1953 or 1968, Model 1968 being a somewhat lighter version of Model 1953. Model 1968 weighs 22 tons, and its training rate is 40 deg/sec (elevation 25 deg/sec). The rate of fire is 78 rds/min in recent weapons (60 in older ones). Claimed maximum effective range is 15,000 m against surface targets and 8,000 m against air targets, presumably reflecting better steadiness in the older mount. The 1968 version has a 35-rnd ready-use magazine.

The 100-mm Compact can fire preselected 1-, 2-, 3-, or 6-rnd bursts. Ammunition feed is arranged so that rounds can be passed back down into the magazine when others are selected. The ammunition supply consists of a main magazine below the gun, with a 12-rnd secondary magazine (but Creusot-Loire offered 36 rds to the Canadians, for the "City"-class frigate). Both magazines are modular, in 24-rnd palletized units. Rounds are carried up horizontally, by a fixed hoist (duct), into an intermediate 18-rnd magazine that elevates with the gun. From this magazine they are transferred down and around (in a horizontal fan) so that they can be rammed into the breech. Typically the intermediate magazine carries 12 rds (so that it and the secondary magazine carry a total of 24, explaining the figures above). Shells are paired, with an empty space between each pair. The intermediate magazine, which is more typical of smaller-caliber guns, brings the gun into action more quickly and makes for rapid access to alternative types of ammunition.

All of these guns are water-cooled (barrel life 3000 rds), and all have a fuze-setter that allows for adjustments just before a round is loaded into the breech.

Model 1953 (*Jeanne d'Arc*, *Suffren* class, *La Gallissonnière*, *Surcouf* T47 ASW destroyers, and *Commandant Rivière* class) uses an analog FCS with electro-mechanical computer. Model 1968 (*Colbert*, *Tourville* class, *Georges Leygues* class, *Aconit*, *Duperré*, A-69 class) uses a digital FCS. At least in the Compact version, the mount is fully automatic, requiring no on-mount personnel.

In 1980 DTCN announced developmental work on an IR-homing round for this weapon, using a staring IR sensor. DTCN did not expect the IR sensor (which drove fins at the base of the shell) to be sensitive enough to ensure a hit on an approaching sea-skimming missile. Instead, the shell was provided with a proximity fuze and a relatively large warhead. The homing round project was canceled in 1990.

At Bourget Naval in October 1990 Creusot-Loire showed a remotely controlled Compact Mk 2 mount with short reaction time ("power on" to first shot in less than 10 sec). Maximum rate of fire is 90 rnd/min using a 13.5-kg ball prefragmented shell with high-performance fuze. The mount stores 66 ready-use rounds in its basic version (42 of 1 type, 12 each of 2 others) or 114 in a large-capacity version (90 of 1 type, 12 each of 2 others). It allows for instant selection among 3 types of ammunition, has an automatic and reversible reloading system, and has 3 selectable rates of fire (90 [reducible to 85], 45, and 20 [both of the latter are adjustable] rnd/sec). Barrel life is 6000 rnd (3000 heavy rnd). Elevation rate is increased to 35 deg/sec. Standard deviation in firing is less than 0.5 mrad. The main improvements in the design are in operability and reliability.

Creusot-Loire also showed a modernization program, 100TR (*tourelle à technologie renouvée*) with a reduced radar cross section. This version is considered good for at least 7 yr without servicing. Local wear is reduced by remotely locking the movable components when they are at rest (they unlock automatically when the turret starts up).

◆ 57-mm M1951

Caliber: 57-mm/60 (5.73-lb projectile)
Rate of Fire: 120 rnds/min/barrel
Muzzle Velocity: 865 m/sec [2840 ft/sec] [originally 3018 ft/sec]
Maximum Range: 13,000 m (5,000 m effective antiaircraft) [14,200/5500 yd] **Elevation/Depression:** +94/-10 deg
Ammunition Capacity: 80/rnds/barrel **Weight:** 16 tons

A French 57-mm/60 twin gun mount on board the missile destroyer *Dupetit Thouars*, 1964. The radars are U.S.-supplied SPG-51s, to control the Tartar missile shown on its launcher. (U.S. Naval Institute)

The gun is the postwar Bofors 57-mm/60, a scaled-up version of the wartime 40-mm/60. The mount is of French design but retains Bofors's fan-feed system for supplying ammunition. The fan feed is joined at the trunnion axis by an inverted-U feeder-hoist extending down to an automatic-feed ready-service box on the deck of the mount; the total of 80 rnds per gun includes box, feeder hoist, and fan feed. The ready-service box in turn is refilled by hand (at 40 rnds/min) from a hoist turning with the mount, extending down to a handling room below. Bofors produced its own mounting, described in the Swedish section. This once-common gun survives on board the French cruiser *Colbert* and the missile destroyers *du Chayla* and *Dupetit Thouars*, having been superseded in French service by the single automatic 100-mm gun (which is not much heavier).

◆ 30-mm (CAS 62 mounting)

Caliber: 30-mm/70 (0.42-kg projectile)
Rate of Fire: 650 rnds/min
Muzzle Velocity: 1000 m/sec [3280 ft/sec]
Effective Range: 2800 m [3000 yd; maximum range 9300 yd]
Training Rate: 50 deg/sec (elevation 40 deg/sec)
Elevation/Depression: +83/-18 deg
Ammunition Capacity: 215 rnds
Weight: 3620 kg [3920 kg including ammunition] [7980/8640 lb]

This power-operated mount, carrying the HS 831A gun, is found only in the frigates *Balny*, *E. de V. Henry*, *Protet*, and *Victor Schoelcher*. These data may refer to a modified version of the mounting in the *Commandant Rivière* class, since these ships originally had an ammunition capacity of 300 rnds per gun, loaded hydraulically. Other ships in this class are armed with single 40-mm guns.

◆ SAMOS

SAGEM's close-in weapons system (SAGEM Anti-Missile Optronic System) uses the General Electric 30-mm GAU-8/A Gatling gun, the same weapon as in the Dutch *Goalkeeper* (see entry below for details). SAMOS competes with *Satan* for the French Navy CIWS requirement and was announced in 1986. There is no associated radar; the gun relies entirely on electro-optical tracking by a Volcan FCS. That tracking avoids multipath reflections from the sea but is presumably subject to limitations of weather and daylight. The Volcan weighs about 150 kg, containing a biaxially stabilized optical sight for tracking,

SAMOS test-firing. (SAGEM)

plus fixed television, IR, and laser sensors. Gun elevation/depression is limited to +83/-19 deg.

The 30-mm gun can be supplemented by 4 *Sadral* missiles atop the gun mount, to extend maximum range from 2-3 km out to 6 km.

SAMOS was demonstrated at the French navy's Gavres range in October 1987, against a *Rushton* target. The target was engaged at 1100 m, and the first hit was made at 850 m, in the area of the IR flare at the rear of the target. The acoustic miss-distance indicator was destroyed on the 28th round, and the system made at least 3 hits before the target disappeared.

Thomson-CSF ceased to market the competing weapon, *Satan*, when it acquired *Signaal* and the rights to *Goalkeeper*. For the details of *Satan*, see the previous edition.

◆ GIAT 20-mm

Caliber: 20-mm/90 (255-g projectile)
Rate of Fire: 650-720 rnds/min
Muzzle Velocity: 1050 or 1250 m/sec [3440/4100 ft/sec] (HE/AP)
Maximum Range: 10,020 or 6,770 m depending on ammunition [10,960/7400 yd]; effective range 2000 or 1200 m [2200 or 1300 yd]
Training Rate: manual
Elevation/Depression: +60/-15 **Ammunition Capacity:** 300
Weight: 336 kg [741 lb] empty **Working Circle:** 2.23 m

The DCAN gun mount for the new GIAT-CN-MIT-20F2 gun has two 150-rnd magazines. This weapon arms the Tripartite minesweepers, and there are also army and air versions. This gun is based on the GIAT CN-MIT 20 M693 (Canon Mitrailleur 20-mm Modèle 693), formerly the Hispano Suiza 820. The naval version entered production in 1983 and is currently used by France, Belgium, the Netherlands, and Indonesia.

A GIAT 20-mm gun (20F2) on board the Dutch minesweeper *Haarlem*, 1987. (R. Cheung)

The French GIAT Affut 15 mounting for the 20-mm M621 gun. The gun fires 750 rounds/min, the mount carries 160 rounds. Elevation limits are $+45/-10$ deg, and total weight (without ammunition) is 167 kg. (GIAT)

At Farnborough in 1988 GIAT displayed a naval version of its M621 20-mm low-recoil gun, which had previously been shown only on land and air mountings. It is typically carried by helicopters and small aircraft. Muzzle velocity is 980–1030 m/sec [3215–3380 ft/sec], depending on the type of ammunition, and cyclic rate is 750 rds/min (an alternate rate, 300 rds/min, is available in the aircraft version). The naval mounting is similar to a land mounting (Army 15A) already shown and carries 160 rds (total weight, presumably without ammunition, is 184 kg [406 lb]), with elevation limits of $+45/-15$ deg. A collimator sight is provided. Recoil is minimized by a muzzle brake and a shock-absorbing mount. Total gun length is 2.207 m [86.9 in], and without the mount the gun weighs 47 kg [104 lb] in its aircraft version.

In contrast to the 20F2, this weapon is 73 calibers long. Development began in the late 1970s, and naval installations began in the mid-1980s. Fifty have been sold, to 4 navies. French-supplied 20-mm guns are used by the Belgian, Djibouti, Gabonese, Indonesian, Madagascar, Mauritanian, Moroccan, Dutch, and Senegalese navies, but many of these weapons may be older 20-mm guns originally made in Britain or in the United States.

◆ GIAT AAT 52 and NF-1

Caliber: 7.5-mm (NF-1, 7.62-mm)
Rate of Fire: 700 rds/min (900 in NF-1) (effective rates: 200–300, 250–300, respectively)
Muzzle Velocity: 832 m/sec (NF-1: 830 m/sec)
Maximum Range: 2000 m (see below)
Elevation/Depression: $+55/-30$ deg
Ammunition Capacity: 200-rnd box
Weight: 17.6 kg empty (25.10 kg loaded) (NF-1)

These are standard auxiliary weapons in the French navy and in the navies of the former French colonies; they are equivalent in function to the U.S. 0.50. The 7.5-mm AAT 52 (*Arme Automatique Transformable Modèle 52*) was the standard postwar French light machine gun; it entered naval service in the late

1950s. The navy uses the heavy-barrel version (with a 23.5-in barrel, rather than the 19.3-in barrel of the light version). The belt feed and delayed-blowback action are derived from those of the wartime German MG42.

NF-1 is a NATO-caliber (7.62-mm) version. These guns are sighted out to 2000 m, but effective range is 1200 m.

The French navy uses a standard pedestal mount (14A) bracketed to a bulwark (data above). There is also a series of Creusot-Loire pintle mounts, designated P127A for the U.S.-supplied 0.50-caliber Browning M2 HB, CP 80A for the 7.62-mm FN machine gun, and CP 52A for the NF-1. With a gun, P127A weighs 82 kg empty and 125 kg loaded. Elevation limits are $+50/-15$ deg.

◆ Laser Weapon

The French weapons development organization, DGA (*Délégation Générale de l'Armement*), is testing a laser weapon, LATEX (*Laser Associé à une Tourelle Experimentale*), a 40-mW laser coupled to an Aerospatiale aiming system. DGA began the program in 1986. In November 1989 it was reported that a laser weapon had been fired at a range of 700 m against a missile head and an aircraft fuselage panel. DGA claims that the laser produces sufficient power, 10 kW/cm², to seriously damage an aircraft fuselage. In 1990 the laser is to be fired at a target flying at 250 m/sec at 2000 m. DGA is seeking European partners for a further laser-weapon program.

GERMANY (WEST)

◆ Mauser Vierling

Caliber: 27-mm/63 (1700-mm barrels) (HE, TP, APFSDS ammunition)
Rate of Fire: 1700 rds/min/barrel
Muzzle Velocity: 1200 m/sec [3940 ft/sec]
Training Rate: 150 deg/sec (elevation 150 deg/sec)
Elevation/Depression: $+80/-15$ deg
Ammunition Capacity: 1440 rds
Weight: 3500 kg (including ammunition) in lightweight version (heavier version, approx 4000 kg)

Development of the quadruple 27-mm CIWS (Vierling) based on the Mauser aircraft gun began as a private venture in 1987. The Mauser does not need the half-second warm-up period of other CIWS because it is gas operated rather than electrically operated. A new APFSDS round was developed specifically for this application. The first prototype was completed in 1989. It showed 4 barrels in diamond formation. The magazines (375 rds/gun) are fixed to the base of the mount, feeding their belts to the elevating mass. The project was shelved early in 1990, but it was revived during the year (with some funding from Diehl), and a model of a lightweight mount (with no deck penetration) was displayed at Defendory in October 1990. Its barrels are in 2×2 arrangement, in a massive turret that very nearly covers the guns altogether. Most of the protruding length of each barrel is encased in a box that covers all 4. Although the German navy has been unable to provide development funds, sea trials on board a German fast attack boat are scheduled for 1991. Ultimately, the Vierling may arm German ships without any other specialized antimissile weapon, as well as any future German fast attack boat.

◆ Rhinemetall 20-mm Mk 20 Rh202

Caliber: 20-mm **Rate of Fire:** 1000 rds/min
Muzzle Velocity: 1050 m/sec (HEI-T, TP-T ammunition) or 1100 m/sec (API-T ammunition) or 1150 m/sec (APDS-T) [3440/3770 ft/sec]
Maximum Range: 2000 m effective range [2200 yd]
Elevation/Depression: $+55/-10$ deg
Ammunition Capacity: 200 rds, linked, in 2 boxes
Weight: 408 kg total; 74 kg ammunition [899/163 lb]
Working Circle: approx 2.45 m [96.5 in] radius

This gun was developed in the early 1960s, and a naval version was announced in 1973 on the S.20 pintle fork mounting.

20-mm Rhinemetal gun on board the Irish *Eithne*, 1986. (Author)

The gun is gas-operated, with a rigid bolt, fed by a belt from its right-hand side. On land, it is carried by the Marder APC. The gun is designed to minimize recoil forces and for long barrel life. As offered in 1973, it had only a speed ring sight, although a lead computing sight was offered as an option. Users are West Germany, Greece (on a Wegmann mount), the Bahamas, Barbados, Indonesia, Ireland, and Thailand.

Norway uses the same low-recoil gun in a different mounting designated KV-SK/20 (derived from the FK20-2 field-gun mounting). Elevation limits are $+70/-15$ deg, and the working circle is 1730 mm. Total weight is 400 kg without ammunition. This gun is manufactured by Kongsberg (now renamed Norsk Forsvarsteknologi). Norway also uses this gun in its coast defenses, to protect larger guns from close-in air attack and from infantry.

ITALY

◆ OTO-Melara 127-mm/54 LW

Caliber: 5-in/54 **Rate of Fire:** 45 rnds/min
Muzzle Velocity: 807 m/sec [2650 ft/sec]
Effective Range: 15,000 m surface; 7000 m antiair [16,400/7660 yd]; maximum range 23,680 yd
Training Rate: 40 deg/sec (elevation 30 deg/sec)
Elevation/Depression: $+83/-15$ deg
Ammunition Capacity: 66 rnds (3 drums) **Weight:** 37.5 tons
Working Circle: 6.108 m [240.5 in]

This gun is a lightweight equivalent of the U.S. Mk 45, enjoying a higher rate of fire and capable of higher elevation for antiaircraft use. The light weight is achieved by using light alloys and a fiberglass shield. The gun is fitted with a muzzle brake. 127-mm/54 loads from 2 drums, a third being loadable while the gun fires. Each drum can, therefore, be loaded with a separate type of ammunition. The type of ammunition (surface, air, pyrotechnic, or chaff) can be selected during firing. Two oscillating arms (which include fuze-setters) strip rounds from the vertical hoist and place them on loading trays. Mounting reaction time is 5 sec. The ammunition is the standard U.S. semifixed type, the ammunition being brought together only at the bottom of the 2 fixed-structure hoists.

This weapon has been exported to Argentina, Canada, and Nigeria, and is to arm the new Japanese Aegis destroyers.

HMCS *Athabaskan* fires her OTO-Melara 5-in/54 gun, 1980. (Canadian National Defence HQ)

◆ 4.7-in

Caliber: 120-mm/45 **Muzzle Velocity:** 850 m/sec [2790 ft/sec]
Maximum Rate of Fire: 7 rnds/min **Training Rate:** manual
Elevation/Depression: $+33/-10$ deg
Maximum Range: 14,500 m [15,900 yd]
Working Circle: 3.96 m radius [155.9 in]
Weight: 16,900 kg [37,250 lb]

This pre-World War II weapon survives only on board Paraguayan *Paraguay*-class gunboats built by Odero in 1931. Presumably the 4.7-in is the 1924 twin destroyer mount carrying the Vickers-Terni gun, data for which are given here.

◆ OTO-Melara 76-mm/62 Compact Mounting

Caliber: 3-in/62 **Rate of Fire:** 85 rnds/min
Muzzle Velocity: 925 m/sec [3034 ft/sec]
Maximum Range: 8000 m surface; 4000–5000 m antiair [8700/4400–5500 yd]
Training Rate: 60 deg/sec (elevation 35 deg/sec)
Elevation/Depression: $+85/-15$ deg
Ammunition Capacity: 80 ready-service (drum magazine)
Weight: 7.35 tons **Working Circle:** 208 in (radius)

76-mm/62 is one of the most successful recent medium-caliber weapons, widely exported. This gun is manufactured under license in Spain and in the United States (as the Mk 75). The single feed drum, holding 70 rnds, surrounds the screw feeder hoist (6 rnds) leading up to a station below the left trunnion. Two arms alternately pick up rounds and place them on a loading drum (4 rnds) at the breech. The drum feeds rounds into a loading tray, which receives the spent cartridge case as

The OTO-Melara 76/62 Compact, on a fast attack boat. (L. Van Ginderen)

the gun recoils. As the gun runs out after recoiling, the tray feeds in the next round. The drum around the base of the hoist can be reloaded while the gun fires. Light overall weight is achieved by using light alloys and a fiberglass shield. Recoil forces are reduced by a small muzzle brake.

The latest version, "Super Rapido," was designed specifically for antiship-missile defense. It weighs 7.5 tons and carries 85 rnds on the mount (selectable 1, 10, or 120 rnds/min; on trials, a gun achieved 139 rnds/min). To achieve much higher rates of fire, OTO-Melara modified the ordnance itself, as well as the feed, the ammunition, and the fuzing. The recoil length and the firing cycle have been shortened. Ramming is no longer part of the sequence in which the spent cartridge is ejected. In redesigning the feed, care had to be taken not to chamber the round at excessive translational speed (which could have damaged it). Some operations are now performed in parallel instead of in series (as in the original Compatto). Because the magazine is now independent of the turret, the feed can be interrupted to insert different types of ammunition, a feature that makes the guided shells described below more attractive. Total firing cycle time has been reduced from 0.7 to 0.5 sec. Accuracy has been improved, partly because the moving parts (which affect accuracy) have been made lighter. The loading tray is particularly critical, in that it moves transversely and thus can shake the gun off aim. In the Compatto, it weighs 50 kg and travels 280 mm, but these figures are reduced to 18 kg and 140 mm in the Super Rapido. Such improvements reduce the standard deviation of shots at 1000 m to 0.3 mrad, some recent small-caliber ASDM weapons have dispersions of over 2 mrad at that range.

Because the feed in the Super Rapido is quite different from that of the earlier Compatto, the earlier guns cannot be converted to the later standard. However, there is a retrofit kit that converts the earlier gun to 100 rnds/min; kits have been supplied for evaluation to the Italian, German, and U.S. navies. The Royal Netherlands Navy has bought 2 kits and has purchased the Super Rapido gun for its M-class frigates. Super Rapido has also been purchased to arm Danish Standard Flex 300s, to arm Singaporean 62-m fast attack craft, and to be the main gun armament of the rebuilt Canadian "Tribal"-class destroyers. The Super Rapido has been adopted for the new Italian *Animoso* class and for the mid-life modernization of the *Audace* class. In the case of the *Animoso*, the Super Rapido replaces the twin fast 40-mm gun of earlier ships of this type.

In the course of developing the Super Rapido, OTO-Melara considered introducing a new low-RCS turret, but decided not to abandon the current shape. The company did harden the turret shell (to resist an overpressure of 1 rather than 0.5 kg/cm²).

OTO-Melara developed a new prefragmented round for the new gun, filled with tungsten cubes rather than the spheres used in earlier shells. This filling shifts more of its total mass toward the outer body as it spins, making for a greater moment of inertia about the projectile's axis and thus for better stability in flight. The shell body is machined inside and outside rather than forged, so the actual center of gravity is very close to the theoretical location, on the shell axis; that makes firing more predictable. This prefragmented shell, made by OTO-Melara and by SNIA-BPD, weighs 6.3 kg and has a lethal radius of 10 m. It incorporates a new proximity fuze to ensure that it will burst ahead of an incoming missile. OTO-Melara is developing a new IR fuze to replace the current doppler type.

There are also 2 new projectiles for surface engagement: SAPOM (6.35 kg, with 0.455 kg of Compound A3 HE) and extended-range SAPOMER (6.5 kg, 0.480 kg HBX-1). Both are semi-armor piercing with base fuzes.

The Italian navy considers Super Rapido an effective anti-missile weapon, as witness its abandonment of the twin Fast Forty in the new *Animoso*. OTO-Melara estimates that, using a Dardo FCS, Super Rapido could begin engaging incoming missiles at about 6000 m, the first rounds arriving at about 5500 m. Given such a long first-engagement range, a single gun should be able to deal with 4 subsonic sea-skimmers, arriving on courses 90 deg apart, before any reached 1000 m.

There is also an older 76-mm/62 (from which the Compact mount was developed), with a muzzle velocity of 850 m/sec, which fires 60 rnds/min. The older gun is recognizable by its more angular gunhouse. This weapon is currently in service only in its single version; a twin mount, with barrels stacked vertically, was its predecessor.

Two course-corrected 76-mm shells are being developed.

OTO and BAe (later joined by Selenia/Elsag and Ferranti) are developing CCS (Course-Correctible Shell); BAe provides the on-board electronics package. First tests were conducted in 1987, then firing trials in 1989, with trials on board an Italian warship scheduled for 1991. There are 6 small thrusters at the shell's center of gravity (the original design called for 10), and 4 fins deployed from the base of the shell reduce the spin rate to the point at which the rockets can be effective. This round can be mixed with conventional unguided rounds. Guidance (for a 1-shot correction of up to 10 deg) is by radio command or modulated laser. The projectiles are not tracked; rather, their course is predicted by the ship's ballistic computer based on known conditions. Projectile length is increased 51%, 355 to 536.5 mm, but the use of light alloys keeps the weight down to 6.3 kg. Fin span is 270.3 mm. Explosive charge is reduced from the present 0.73–0.75 kg, but better accuracy should make for greater lethality. Since the total length of the projectile plus charge cannot be increased, propellant must be reduced, and shell speed is reduced by about 85 m/sec. Effective range is 4–6 km, and shells can be made to deviate up to 400 m laterally from their original points of aim. These shells will be fired at a probable point of interception, then flown toward any new probable point. The cost per round was 15–20 times less than the cost of a point-defense missile such as Mistral. This shell is compatible with the NA 20 and NA 25 FCSs.

Signaal, in collaboration with Diehl of West Germany, is developing CORAS (Correctable Ammunition System). Signaal claims that kill probability vs. incomers is improved by a factor of 4, at less than 25% of the cost of a missile system such as RAM or Sea Sparrow. The shell controller unit is coupled to the ship's FCS, which continuously computes a predicted hitting point (PHP), and relays data to all shells in the air via a simple radio link. The shell corrects course by releasing gas, as in the Bofors corrected-course 40-mm shell. The major problem is the lack of a horizon reference; it was solved by having the shell measure the strength of the up-link electro-magnetic field. As of mid-1989, Signaal was seeking further partners, such as OTO-Melara, Martin Marietta, and Bofors. The ammunition electronics is still under development; in computer simulations, Signaal claims to have improved the range for effective single-shot hit from 600 to around 2500 m. CORAS thus forms a complement to Goalkeeper, filling the gap between close-in gun range and effective missile range (about 3000 m). Several potential customers, including Dutch and FRG navies, expressed interest, and firing trials were conducted in the latter part of 1989.

As of late 1990 it seemed likely that the 2 teams would merge.

OTO-Melara also offers a dual-purpose (antiship and anti-aircraft) MOM (Multirole OTO-Melara) round. It has a proximity fuze and contains tungsten cubes embedded in the casing. An extended-range round is under development, and there is a new base-detonating delayed-action fuze.

◆ Breda 40-mm

Caliber: 40-mm/70 **Maximum Recoil Length:** 100 m [3.94 in]
Muzzle Velocity: 1025 m/sec (HE) [3362 ft/sec] 1350 m/sec [APFSDS] [4428 ft/sec]
Maximum Horizontal Range (HE): 12,500 m [13,700 yd]
Maximum Altitude: (HE) 8700 m [28,500 ft]
Rate of Fire: 900 rnds/min/mount
Maximum Elevation/Depression: +85/-13 deg
Working Circle: 2.902 m [114.3 in]

Data are for the Twin Fast Forty.

Breda produced 2 versions of the twin 40-mm/70 (see Bofors, below). One was a compact twin mount. It in turn was suc-

A Breda twin 40-mm gun on board the German training ship *Deutschland*, 1985. (R. Cheung)

Ammunition flow in the Breda twin Fast Forty (40-mm) gun. (Breda)

ceeded by the Twin Fast Forty. The main features of the new mount are a new recoiling mass, a dual-feed system, and digital servo control. The new recoiling mass reduces the recoil stroke by better than half to speed the firing cycle. The dual-feed system employs a lower magazine, under the mount platform, plus an upper magazine split between the 2 guns. Both upper and lower magazines feed into each gun.

The Fast Forty exists in 2 magazine versions, Type A (736 HE rnds in 7 horizontal layers) and Type B (444 rnds in 4 horizontal layers). In each case, the upper magazine contains 200 APFSDS (Armor-Piercing Fin-Stabilized Discarding Sabot) rnds.

The Compact version has a similar ammunition capacity and is rated at about 600 rnds/min (300 per gun). Total weight without ammunition is 5500 kg for Type A, 5300 kg for Type B (7300 kg in Type A, 6300 kg Type B, with ammunition). Training and elevation rates are 90 and 60 deg/sec. Breda claims that this weapon shows a much shorter reaction time than the earlier Bofors gun and saves considerable manpower. However, at least when the Compact version is used in the antimissile role, the most important improvement is much greater accuracy. In June 1976 official Italian navy trials showed a mean dispersion of 1 mrad, compared to the manufacturer's estimate of 1.8 mrad. Breda/Bofors calculated that, given an error rate of 3 mrad (which is very conservative), and missile accelerations of 2.8 Gs in the vertical and 4.7 Gs in the horizontal, the gun should have a 30% probability of destroying an incoming air target outside

900 m (i.e., outside the range at which ballistic fragments would be a problem).

In Italian service the usual FCS is Dardo, with an Orion RTN-20X radar (see above under shipboard radars and FCS).

Breda also manufactures conventional open-topped 40-mm mountings carrying air-cooled guns. Type 106 is a twin 40-mm/70; Type 107 is the corresponding single mount. Each gun carries a 32-rnd Breda autofeeder that elevates with the gun, or it can be loaded with the usual 4-rnd clip. Train and elevation speeds are both 95 deg/sec. Type 106 serves in the West German navy (e.g., in the *Hamburg* class).

Type 64 is a twin mount, each gun carrying a 100-rnd automatic magazine. Total weight without ammunition is 7900 kg, and training and elevation rates are 85 and 95 deg/sec.

Type 564 is a single 40-mm/70 carrying a Model 1971 144-rnd automatic magazine. This weapon is also marketed as the Breda-Bofors 350P. Total weight without ammunition is 3300 kg. Training and elevation rates are 80 and 45 deg/sec.

For defense against sea-skimming missiles, these guns use ammunition with a special Fratelli Borletti proximity fuze that adjusts its fuzing range to the altitude, to avoid premature bursts. At 40 m above the sea, the burst range is 4.5 m; at 20 m, about 3 m; and at 5 m, about 1 m.

Breda exhibited the prototype of a new single-barrel Fast Forty

Breda twin 40-mm/70 compact naval guns. (Breda)

Breda's single Fast Forty mount, on display in 1989. Behind it is the combined chaff and Mistral launcher. (Breda)

antiaircraft cannon at the Mostra Navale exhibition in Genoa in May 1989. There are 3 versions: remotely controlled (Type A) and locally controlled (Types B and C). Type B uses a simple on-mount FCS. In Type C the mount is provided with a micro-computer-based FCS employing a stabilized television line of sight independent of the line of fire and a laser range-finder. Power is provided in part by a converter that accumulates recoil energy as the gun fires. Compared to previous 40-mm/70 weapons, this one uses a new oscillating mass (designed by Breda) that substantially reduces recoil distance (from 230 to 100 mm) and time, allowing a higher rate of fire (450 rnds/min compared to the previous 300 rnds/min). Changes include a new rammer taking the round directly from the feed position to the breech-block closing position. The mount carries two 42-rnd magazines, and 5 more rnds are accommodated in the gun feeder and hopper, for a total of 89 rnds on the mount. Elevation limits are $+83/-13$ deg.

Breda claims that a twin Fast Forty, firing 900 rnds/min, can kill an incoming supersonic missile, flying a straight path, using proximity-fuzed bursts, at a range as great as 3000 m. At such ranges it is probably sufficient to destroy the missile's control surfaces. The mount automatically shifts to the heavier APDS rounds when the missile reaches a range of 1000 m.

◆ Oerlikon/OTO 35 mm

Caliber: 35 mm/90 (1.56-kg round, including 550-g shell) [3.43/1.21 lb]
Rate of Fire: 1100 rnds/min (550 rnds/min/barrel)
Muzzle Velocity: 1175 m/sec (3850 ft/sec)
Maximum Range: 6000 m (5000 m air target) [6600/5500 yd]
Training Rate: 120 deg/sec (elevation 70 deg/sec)
Elevation/Depression: $+85/-15$ deg
Ammunition Capacity: 800 (400/barrel)
Weight: 6400 or 6600 kg with ammunition (through- or above-deck version) [14,100/14,500 lb]
Working Circle: 3500 mm [137.8 in]

1 - Gunhouse of reinforced fiberglass. 2 - Mantlet plate. 3 - Left feed belt. 4 - Right feed belt. 5 - Mauser elevating mass. 6 - Access door. 7 - Training power drive. 8 - Spent case and link deflector chutes. 9 - Elevation toothed sector. 10 - Firing mechanism. 11 - Booster. 12 - Guide. 13 - Firing limiting device. 14 - Elevation power drive. 15 - Spent case and link evacuation tubes. 16 - Training lock. 17 - Elevation lock. 18 - Auxiliary junction box. 19 - Magazine.

Breda twin 30-mm compact mounting. [Breda]

This Oerlikon type GDM-C can be compared to the Oerlikon-Bührle GCM-A01 manufactured under license in Britain (see British guns below). 35-mm was produced as a private venture, and its design emphasizes light weight. Unlike the Swiss mount, the OTO-Melara mount carries its 2 guns on either side of a central mass. A special dual feed allows a choice, for each gun, between the main ammunition container and a separate container holding 20 rnds of special ammunition. The 2 guns are KDAs, slightly lighter than the clip-fed KDCs of the Swiss mount.

To reduce weight, OTO-Melara used aluminum extensively in the mount and also used a watertight fiberglass shield. The unit as a whole is interchangeable with the OTO-Melara 76/62 Compact gun. The design emphasizes quick reaction, and time from off to fire is 2.6 sec. High muzzle velocity and low drag make for short time of flight, e.g., 6 sec to 4400 yd.

This gun was very nearly selected as the main armament of the U.S. *Perry*-class frigate, but the OTO-Melara 76/62 (U.S. Mk 75) was chosen instead. Similarly, 35-mm was nearly selected for the *Pegasus*-class hydrofoil. The U.S. Navy bought 1 mount for evaluation, but no trials were conducted.

◆ Breda 30-mm

Caliber: 30-mm/82 (369-g projectile) [0.813 lb]
Rate of Fire: 800 rnds/min
Muzzle Velocity: 1040 m/sec (HE) [3410 ft/sec] 1220 m/sec (APDS) [4000 ft/sec]
Maximum Range: effective range 3000 m (time of flight 5.36 sec with HE round) [3300 yd]
Training Rate: 140 deg/sec (elevation 80 deg/sec)
Elevation/Depression: $+85/-13$ deg
Ammunition Capacity: 160 rnds
Weight: 1200 kg empty/1330 kg loaded [2640/2930 lb]
Working Circle: 2.72 m [107.1 in]

This Breda single mounting for the German Mauser MK 30-mm Model F gun uses a dual feed and standard NATO ammunition (as in the U.S. GAU-8). In effect 30-mm is a scaled-down version of the Breda twin 40-mm gun. The 30-mm gun was announced in 1984. A new locally controlled version was announced in 1986. It is gyro-stabilized and joystick controlled using optics that are line-of-sight stabilized. Aim-off is automatically calculated while the target is kept in sight. Breda claims that the new version should be effective against surface targets at up to 3000 m.

There is also a twin compact version, announced in 1980, carrying 1100 (Type B) or 2000 (Type A) rnds. Training and elevation rates are 130 and 75 deg/sec. Elevation limits are

Breda single compact 30-mm mounting. [Breda]

+80/-13 deg, and the working circle has a radius of 2.523 m. Marconi and Breda jointly proposed a close-in version of the twin 30-mm mount using a collocated Marconi 440-series radar mounted atop the shield, under the designation Sea Cobra. This weapon was tested in England (on the Fraser Gunnery Range) in the early summer of 1988, against Rushton targets. The first operational installations were made in 1987, for the Italian Customs Service.

◆ Breda-Oerlikon 25-mm KBA

Caliber: 25-mm/80 **Rate of Fire:** up to 600 rnds/min
Muzzle Velocity: 1100-1360 m/sec [3600-4460 ft/sec]
Maximum Range: see below
Training Rate: manual (power-assisted)
Elevation/Depression: +50/-15 deg
Ammunition Capacity: 200 rnds
Weight: 660 kg without ammunition [1455 lb]
Working Circle: radius 2.31 m [90.9 in]

This weapon, announced in 1988, is the first result of a new collaboration between Breda and Oerlikon Italiana. KBA is intended as a direct replacement for the earlier manual 20-mm gun. Firing much more powerful ammunition, it is too heavy to handle entirely manually, particularly on board a lively ship. The mounting, therefore, provides hydraulic power assistance, not at all times, but only when power is needed. Power assistance is triggered by the amount of inertia resisting the gun's movement. In effect, the power assistance cancels out the unpredictable inertial forces due to ship motion, so that the gunner always applies only the degree of force that would be needed if the ship were not moving at all. The gunsight, which is ranged out to 2000 m, is fixed to a parallelogram system: the gunner can remain standing at any gun elevation, instead of having to crouch uncomfortably as in earlier manually operated guns. Light alloy construction is used to hold down the total weight of the mounting. This weapon retains the dual-feed system of the earlier land-based KBA gun, permitting the mounting to be reloaded while it is still available to fire.

Breda has now mounted the Oerlikon 25-mm KBB gun in versions of its existing 30-mm and 40-mm mounts. The first such weapons were displayed at the Mostra Navale exhibition in Genoa in May 1989: single and twin mountings.

The single mounting employs dual-feed (two 80-rnd boxes) and on-mount buffer batteries sufficient for up to two hundred 360-deg rotations (or their equivalent in elevation and depression). They are charged by the ship's power, and they permit gun operation to continue in the event ship's power is no longer available. The locally controlled mounting employs a Breda

The Breda twin 25-mm mounting. (Breda)

The Breda single 25-mm mounting in locally controlled form. (Breda)

The Breda-Oerlikon 25-mm KBB gun. (Breda)

Hawkeye micro-FCS, employing an independent stabilized line of sight. Target tracking is computer-aided (the computer projects ahead a straight trajectory), and range is estimated by using precalibrated reticules (for example, the operator opens fire when the target image coincides with a circle of predetermined lens magnification). The mount can be fitted with an LLLTV in place of the usual daylight television camera, and it can be controlled remotely.

The twin 25-mm mounting employs a specially designed Breda cradle, the bore axes being set unusually close together for accuracy. There are 3 alternative magazine arrangements: Type A (2000 rnds), B (1000 rnds), and C (500 rnds, on the rotating platform).

◆ Myriad

Caliber: 25-mm **Rate of Fire:** 10,000 rnds/min
Muzzle Velocity: 1270 m/sec **Maximum Range:** effective range 1000+ m
Training Rate: 3.0 rad/sec (train 2.5 rad/sec)
Ammunition Capacity: 2000 rnds
Weight: 7700 kg (including ammunition)

This new CIWS, first displayed at Mostra Navale in Genoa in 1989, is a joint venture by Breda, Contraves Italiana, Elsag, and

A model of the new Myriad close-in defensive weapon, at the Paris Air Show, 1989. The canted platform is similar to that employed in the Seaguard system (which Contraves manufactures). As in Seaguard, the director is separate from the mounting. (Author)

Selenia. It employs a pair of Oerlikon 7-barrel 25-mm KBD Gatling guns, which fire the high-velocity ammunition of the Oerlikon KBB gun. KBD is the first application of the Gatling principle to Oerlikon weapons. The associated director carries a pair of radars, a Ka-band (35 GHz) set for acquisition and a W-band (95 GHz) set that takes over at short ranges. With a much narrower beam, the W-band radar suffers less from multipath (reflected in radar nodding).

The logical basis of Myriad is the contention that next-generation antiship missiles will be both supersonic and highly maneuverable, so they may well evade weapons whose FCSs have to predict target motion. Hence, it will be impossible to hit an incoming missile at any great range. The Myriad devel-

Twin 25-mm Gatling guns of a Myriad mounting, showing ammunition feeds. (Breda)

opers argue that, no matter how it maneuvers, a missile must attack a ship through a relatively constricted window close to the ship. The Myriad FCS, built by Elsig, uses known aerodynamic features of the missile to predict the location of the window, 500–1000 m from the ship. The very high rate of fire developed by the twin guns, 10,000 rnds/min, saturates this window. The ammunition is a special AMDS (antimissile discarding sabot) type, using a tungsten-alloy rod penetrator 14.5 mm in diameter (mass 156 g). As in the U.S. Phalanx, the kill mechanism is penetration of the missile warhead to ensure its detonation; the manufacturer argues that only such destruction will ensure against missile fragment damage to the ship. Muzzle velocity of the AMDS round is 1270 m/sec (1285 m/sec for the APDS-T round). Remaining velocity at 500-m range is 1190 m/sec; time to 500 m is 0.41 sec. Remaining velocity at 1000-m range is 1113 m/sec (time to 1000 m is 0.84 sec).

The gun itself has a new patented antihangfire safety mechanism, which precludes firing ammunition from an unlocked breech.

Like the existing Seaguard weapons, Myriad is mounted on a tilted platform, so it can engage zenith attacks. The mounting carries 2000 rnds in 4 boxes, 2 per Gatling (so that each gun can switch between 2 types of ammunition). Total weight, including ammunition, is 7700 kg. Each of the 2 guns weighs 1600 kg, including its 1000 rnds of ammunition.

Gun and director are connected to a standard MAGICS console via the standard 10-Mbit/sec data bus (MHIDAS); the system is arranged so that many trackers and many guns can be interconnected through a single bus. The system can accept search-radar data and conduct its own threat evaluation before firing.

The Myriad program started in 1988, and the prototype should be completed in 1990, with integration and testing completed by the end of 1991, and firing trials in 1992. It may be offered to the Italian navy to replace Dardo in new ships.

NETHERLANDS

◆ Goalkeeper (SGE-30)

Caliber: 30-mm **Rate of Fire:** 4200 rnds/min
Muzzle Velocity: 3318 ft/sec (3900 ft/sec firing discarding sabot ammunition, MPDS)
Maximum Range: Engagement range about 2000 m [2200 yd]
Training Rate: 100 deg/sec (elevation rate 80 deg/sec)
Elevation/Depression: +85/-25 deg
Ammunition Capacity: 1200 rnds
Weight: 14,018 lb loaded plus 7766 lb off-mount
Working Circle: 100 in

This close-in weapon developed by Signaal and General Electric uses the latter's 30-mm 7-barrel GAU-8/A Gatling gun. A linear-array X-band search radar on the mount (1.5 × 30/60-deg beam, scanning at 60 rpm) relays the target's range and bearing to the dual-frequency (X- and Ka-band) tracking radar (which uses a Cassegrain dish) on the gun mount. The beamwidth of the X-band tracker, 2.4 deg, is larger than that of the acquisition radar, to assure very rapid acquisition without search. Once the X-band tracker has acquired the target, the 0.6-deg beam of the Ka-band tracker takes over. In automatic operation, the radar limits itself to targets in a 2-7 km range bracket, and with radial speeds of over 150 m/sec. Total reaction time against a Mach 2 sea-skimmer, including automatic detection, IFF interrogation, 90-deg tracker slew, tracker elevation, X-band lock-on, and computer run-in, is about 5.5 sec, the engagement beginning at 1.5 km with maximum kill probability at 300 m. The radar is derived from the Signaal Flycatcher ground AA unit.

The system, using data from its radars, automatically and continuously evaluates and prioritizes targets. Signaal claims that the use of Ka-band (8-mm wavelength) provides a very narrow beam that avoids reflections off the sea (even against sea-skimmers) and, thus, produces no deceptive mirror images. The broader X-band tracker radar captures the designated target, and the signal/noise ratios of the X- and Ka-band tracker radars are continuously and automatically compared to reject clutter and jamming. Both radars have standard anticlutter and ECCM features, such as pulse compression, pulse-to-pulse coherence (for doppler-MTI tracking), frequency diversity, and flexible waveforms (adaptive transmission). Tracking is by monopulse in both frequency bands.

This system employs closed-loop spotting of the type used in Phalanx.

The 30-mm Gatling gun in its EX-83 mount is also the basis of the French close-in weapons, SAMOS and Satan. Signaal chose the GE Gatling gun in preference to the Mauser 30-mm gun, for which Goalkeeper was originally designed, because the quadruple Mauser (SEM-30) could not meet a Dutch navy requirement for 1.7-mrad dispersion; SGE-30 demonstrated 1.2-mrad dispersion in a 6-sec burst (420 rnds).

Goalkeeper on board HMS *Invincible*, 1990. (E. Grove)

Signaal demonstrated the GAU-8/Flycatcher combination in November 1979, against targets at a range of about 1000 m; Goalkeeper is the result, the Dutch navy choosing the GE gun over the Mauser gun in mid-1980.

In 1983 the Royal Navy chose Goalkeeper rather than the VSEL Sea Dragon, a similar EX-83 gun controlled by a masthead Sea Giraffe 150HC and an on-mount tracker derived from the DN181 millimeter-wave radar of the Rapier blind-fire system. Reportedly, this choice was based more on political and economic than on technical factors.

NORWAY

◆ NFT Armored Turret

The projected Norwegian fast attack boat will use a version of the new NFT armored turret developed for vehicles; it is also used (in more heavily armored form) in Norwegian coast defenses (carrying a Rhinemetal 20-mm gun). The power-driven turret, which is controlled by joystick, can carry a 20- or 25-mm gun. It can also operate manually if power is interrupted. The FPB version will carry more ammunition than the standard vehicle version described here.

The NFT turret was developed (with Hagglund of Sweden) for the M 113 armored personnel carrier; initially, this single-operator, welded-steel turret carried an Rh 202 cannon. Ultimately, it carried a Mauser 25-mm Model E cannon with a coaxial 7.62-mm MG 3 machine gun. The combat weight of this version (including 1000 rnd) is about 1000 kg. The bearing ring diameter is 1.2 m. Elevation limits are +50/-10 deg. Power train (not elevation) is up to 90 deg/sec. A newer version, with a higher profile (height 0.605 m above the vehicle roof), carries a dual-feed Rh 202 (200 rnd of 20-mm) and a coaxial 7.62-mm MG 3 (400 rnd) and weighs 850 kg. There are 2 speeds for manual train (there is no power option). Swept radius is 2.3 m.

◆ Raufoss Antiship Warheads

These delayed-action penetrators were developed for the Royal Norwegian Air Force and Navy and are intended to pass through 3-12 mm steel at 0-60-deg impact angles, exploding 2 or 3 m inside the target (average detonation delay is 5 msec). The usual explosive (composition A3) is supplemented by persistent incendiary material in the shell and is intended to ignite diesel oil, bunker fuel, and lubricating oil. The current family consists of:

M78 for 3-in/50 naval guns. This is the only member of the family that lacks incendiary material.

RA79 for 2.75-in aircraft rockets, carrying 460 g of explosive and 70 g of incendiary. Total warhead weight is 5.91 kg. This warhead is designated HEISAP, high-explosive incendiary semi-armor piercing.

M85 for 105-mm coastal artillery, carrying 1.7 kg of A3 and 60 g of incendiary; total weight is 15.1 kg.

M88 for 127-mm coastal artillery, carrying 3.2 kg of A3 and 60 g of incendiary; total weight is 28 kg.

Raufoss also makes training projectiles (TP) for 3-in/50 and 105-mm guns and for the 2.75-in aircraft rocket.

These warheads were first exhibited in 1990. They follow earlier Raufoss work on armor-piercing/incendiary machine-gun and machine-cannon rounds. See the U.S. 0.50-cal machine gun entry for details (the 0.50 is probably the most interesting naval application).

SPAIN

◆ Meroka

Caliber: 20-mm/120 (round weight 320 g, including 102-g projectile) [0.71/0.225 lb]
Rate of Fire: 2 bursts/sec (9000 rnds/min during burst that lasts 0.080 sec)
Ready-use Ammunition: 720 rnds (60/barrel) (2160 in future version)

Muzzle Velocity: 1300 m/sec [4260 ft/sec]
Maximum Elevation/Depression: +85/-15
Weight: 4500 kg on mount; plus 421 kg off mount [9920/928 lb]

A close-in weapons system developed by the Spanish manufacturer Bazan, Meroka is mounted instead of the U.S. Phalanx on board Spanish equivalents of U.S. warships (*Perry* class and the Sea-Control Ship *Principe de Asturias*). Meroka is designed to operate on the basis of target detection (by an associated search radar) at 15,000 m, using its own I-band tracking radar to acquire targets at 5000 m, and achieving first impact at 1500 m and target destruction at 500 m [16,400/5500/1640/550 yd].

Targets are tracked by monopulse, using an on-mount Lockheed Electronics PVS-2 Sharpshooter. In current Spanish installations, targets are designated via a Selenia RAN-12L/X search radar via a Selenia PDS-10 tactical-data console. There is no closed-loop spotting. An optronic system is provided for backup in a jamming environment, and there is an off-boresight tracker to deal with extremely low targets.

Bazan claims that the ammunition is a special hard-core type, for maximum penetration of missile bodies.

The twelve 20-mm barrels are arranged in 2 horizontal rows, very close together.

Meroka. (Bazan)

◆ Sardin

Sardin is a Meroka replacement now under development by Bazan. Reportedly, it will be a hybrid weapon (presumably, guns and missiles); presumably, this project was the reason Spain entered the NATO VSRAD consortium.

SWEDEN

◆ Bofors 6-in DP

Caliber: 152-mm/50 (101-lb shell, 71.8-lb cartridge)
Rate of Fire: 12-15 rnds/min/gun **Muzzle Velocity:** 2950 ft/sec
Maximum Range: 28,400 yd
Elevation/Depression: +60/-10 deg
Weight: 113 tons (no ammunition)

This dual-purpose cruiser gun was designed beginning in 1937, primarily for the Dutch navy. When the Netherlands was

overrun, twin and triple mounts were diverted to the Swedish *Tre Kronor*-class cruisers. These ships have now been discarded, but twin mounts remain on board the 2 former Dutch *de Zeven Provinciën*-class cruisers in the Peruvian navy. Those mounts represent 1 generation of technology beyond the Soviet's triple 6-in mount (*Sverdlov* class) and are roughly comparable to U.S. wartime automatic heavy guns (6-in/47, now discarded, and 8-in/55, in the *Des Moines* class).

This weapon is unusual in that the shell and cartridge case are stowed separately (for ease of handling) but are rammed together into a single round on a cartridge carrier before hoisting to the gun; the weapon, therefore, enjoys the advantages of fixed-round loading. The breech is a vertical sliding wedge, and the loading tray elevates with the gun for all-elevation loading. The design was criticized by British observers on the grounds that the ramming together of shell and cartridge case demanded extraordinarily close production tolerances.

Armor: 4.9-in face and rear, 2-in roof, 1.2-in sides.

◆ Bofors 4.7-in/50 (120-mm)

Caliber: 120-mm/50 (21-kg HE shell; 40-kg complete round) [46.3/88.2 lb]
Rate of Fire: 45 rnds/min/barrel
Muzzle Velocity: 850 m/sec [2790 ft/sec]
Maximum Range: 13,000 m surface fire; 7000 m antiaircraft [14,200/7700 yd]
Training Rate: 25 deg/sec (elevation 40 deg/sec)
Elevation/Depression: +85/-10 deg
Ammunition Capacity: 104 rnds (52/gun)
Weight: 55 tons (67 including rotating platform and ammunition)

Data refer to the twin destroyer mount, which was manufactured for the Swedish, Dutch, and Colombian navies. This gun survives in the 2 Dutch *Tromp*-class destroyers and in several ex-Dutch destroyers transferred to the Peruvian navy. The Swedish and Colombian ships have been discarded.

The twin 4.7-in gun was developed by Bofors (beginning in 1944) as an intermediate weapon between the 6-in/50 and the 57-mm/60. Bofors developed 3 types of loader, a horizontal fan (which was used in the 57-mm mount), a vertical fan, and a pendulum swinging up from the vertical ammunition hoist to the breech. In each case, the loader had to be able to accept rounds at any elevation and then shift them to the elevation of the breech. The pendulum was chosen for this mount. Its arm is pivoted at the trunnion, and it swings between the top of the hoist and a loading position behind the breech; rounds are rammed from the top position directly into the breech. After ramming, the round debullets, i.e., the shell separates from the cartridge case and seats. Bofors claims that this process decreases barrel wear and also retains the cartridge case more firmly in the chamber until the breechblock has closed sufficiently.

Each of the 2 hoists has two 26-rnd hoppers at its bottom, so that both surface and AA ammunition can be carried. It takes 5-15 sec to switch ammunition by turning the hoppers to line up the unused one.

This mount was considered extremely advanced when it appeared in 1950, and about 1953 the Royal Navy considered adoption. The mount was rejected: it was too heavy, too noisy, and not flash- or gas-tight. Reportedly, the Dutch navy found the mount rather too heavy (and vibrations too violent during rapid firing) for the 2700-ton destroyers.

Bofors also developed a single automatic mount of this caliber, designated TAK 120L/50-93, for destroyers or frigates. In Swedish service, this mount would have replaced the twin 120/50 in a later-generation destroyer, but that project died when Swedish naval policy shifted to an emphasis on small coastal craft and submarines. Rate of fire was 70 rnds/min (with a water-cooled barrel), using twin-drum magazines below the mount; range was 21,000+ m (time to 10,000 m was 19.2 sec). Elevation limits were +78/-10 deg. Training speed was 40 deg/sec (elevating speed 30 deg/sec). Total mount weight was 57 tons, including the foundation (with control room) and 300 rnds, and the gunhouse was built of 10-mm steel. Each round weighed

The Dutch cruiser *de Ruyter* (now Peruvian) shows both the Bofors twin 6-in and twin 57-mm/60 (superfiring above the 6-in turrets) guns. (U.S. Naval Institute)

40 kg. The entire mount could be laid by 1 operator, and the gun was liquid-cooled so that it could sustain a high rate of fire. The turret had an unusually low profile. Ammunition feed was by a dual swinging arm (as in the twin 4.7-in gun). The crew was limited to 3. Work began about 1956, the goal being a single self-contained unit including on-mount fire control (as in the contemporary U.S. GUNAR), firing 60 rnds/min. This weapon is interesting as an example of what might be possible if the Swedish navy continues toward larger craft, as it now seems to be doing.

Bofors 4.7-in/50 on board the Dutch destroyer *Friesland*, now discarded (however, sisters are retained in the Peruvian navy). The surface-search radar is the Signaal ZW-01 (now replaced by ZW-06 in the surviving ships); the radar on the foremast is DA-01, and the big air-search antenna aft belongs to LW-02. The fire-control radar is M 1. The foremast carries the standard British DF antennas: FH 4 at the foretop and UA-2 below, for HF and UHF, respectively. (U.S. Naval Institute)

◆ Bofors 4.7-in/46

Caliber: 120-mm (21-kg HE shell, complete round is 35 kg) [46.3/77.1 lb]
Rate of Fire: 80 rnds/min
Muzzle Velocity: 800 m/sec [2620 ft/sec]
Maximum Range: 18,500 m [20,200 yd]
Training Rate: 40 deg/sec **Elevation/Depression:** +80/-10 deg
Ammunition Capacity: 52 rnds ready use (plus 16 in mount)
Weight: 28.5 tonnes (without ammunition or flare launchers)
Working Circle: 6.33 m [249.2 in]

This dual-purpose enclosed gun, for large fast attack craft displacing 600 tons or more, is currently in service only on board 2 Finnish corvettes of the *Turunmaa* class, the minelayer *Pohjanmaa*, and the Indonesian *Fatahillah* class. The barrel is water-cooled, and the gun has a vertical sliding breechblock. There are 2 magazines, 1 fixed to each side of the breech. Each magazine has 5 ammunition channels (5 rnds each), and the gun feeds alternately from each magazine into the ammunition chamber of the autoloader. The dual-magazine arrangement permits loading with 2 kinds of ammunition, so that the type can be switched instantly without interrupting the loading cycle. The enclosure is 4-6-mm steel for splinter protection.

Development (on a private-venture basis) began in 1963, and the first prototype was tested in 1967. This weapon is an adapted antiaircraft field gun. The Bofors designation is TAK 120.

A single Bofors 4.7-in/46 on board the Finnish *Turunmaa*, 1986. (S. Terzibaschitsch)

◆ Bofors 76-mm

Caliber: 3-in/50 (5.9-kg [13-lb] Mk-27 ammunition)
Rate of Fire: 30 rnds/min
Muzzle Velocity: 823 m/sec [2700 ft/sec]
Maximum Range: 12,600 m at 30 deg elev [13,800 yd]
Training Rate: 25 deg/sec (elevation: 25 deg/sec)
Elevation/Depression: +30/-10 deg
Ammunition Capacity: 16 ready-use rnds on the sides of the hoist frame **Weight:** 6.5 tonnes empty

This fully automatic single gun is intended primarily to deal with surface targets. It is controlled by an external director and

Bofors 76-mm gun on board the Norwegian patrol boat *Hvass*. The radome conceals a Signaal WM-26 fire-control radar, and the search radar above it is a Decca TM 1226. The missiles aft are Penguins, and the gun aft is a Bofors 40-mm L70. (G. Koop)

is unmanned, for a low silhouette. The gunhouse is 6 mm thick. This gun is used only on board Norwegian *Storm*-class fast attack craft and on board Singaporean 110-ft "Type B" patrol boats. In both cases the associated FCS is the Signaal WM-26, a "half-egg" incorporating a single TWS radar.

◆ Bofors 57-mm/60

Caliber: 57-mm/60 (5.73-lb shell, 6.27-lb cartridge)
Rate of Fire: 130 rnds/min/gun **Muzzle Velocity:** 3018 ft/sec
Maximum Range: 15,880 yd
Training Rate: 30 deg/sec (elevation 30 deg/sec)
Elevation/Depression: +90/-10 deg
Weight: 68,300 lb (no ammunition)

Bofors developed the 57-mm gun during and after World War II as the natural successor to the 40-mm/70 then under development; the 57-mm/60 is a scaled-up version. The French Model 1951 uses a Bofors-manufactured gun in a French mounting. This gun was also adopted, in a Bofors-designed mounting, by the Dutch and Swedish navies, as a secondary-battery weapon, in an enclosed twin automatic mount. The 57-mm/60 survives on board one ex-Dutch Peruvian cruiser.

With this weapon, Bofors abandoned the 4-rnd clip of the 40-mm gun, theorizing that fire could not be fast enough, and that clips would be far too heavy. Instead, loaders drop rounds into ammunition boxes, which in turn feed 2 fans (quadrant-shaped hoppers). The fans are mounted at the gun trunnions, so that the position of the gravity feed is always constant (horizontal, perpendicular to the gun's axis). The fan itself elevates with the gun, and rounds move along the fan from the perpendicular position to a position directly over the breech. Similar fan feeds can be seen in other postwar Bofors and Breda-Bofors weapons.

◆ Bofors 57-mm/70 Mk 2

Caliber: 57-mm/70 (6.1-kg [13.1-lb] round)
Rate of Fire: 225 rnds/min
Muzzle Velocity: 1025 m/sec (PFHE; 950 m/sec for HCER) [3360/3120 ft/sec]
Maximum Range: 17,000 m [18,600 yd]
Training Rate: 55 deg/sec (elevation 40 deg/sec)
Elevation/Depression: +75/-10 deg
Ammunition Capacity: 120 rnds in cupola, 40 rnds ready to fire
Weight: 6500 kg without ammunition [14,300 lb]
Working Circle: 4.325 m [170.3 in]

Bofors claims that this gun is truly dual-purpose: that it is accurate and agile enough to destroy sea-skimmers (by using proximity-fuzed ammunition and by attempting to set off their warheads); and that, with penetrating (delayed action) HE rounds (HCER, or high-capacity extended-range), it puts more explosives into a surface target in the first 30 sec than any other gun of up to 100-mm caliber. The company claims that 57-mm/70 should be an effective shore bombardment weapon because it can pepper an area with shell fire before the targets can move or take cover. The delayed-action fuze should permit penetration of 20 mm of steel before the round bursts about 2 m inside the target. Bofors claims, too, that using better steel allows reduced shell thickness, so that the shell carries 40% more explosive than its predecessors.

Bofors 57-mm/70 Mk 2.

The loader and the gun mount are 2-sided, so that 2 types of ammunition can be handled simultaneously. Ammunition comes up from the magazine into two 20-rnd cassettes, mounted on a rail behind the gun. When filled, they move into position above, and discharge their ammunition down into, the ready-use magazines. There are also 2 intermediate cassettes, each holding 20 rnds, so that the cupola (turret) carries 60 rnds (2 cassettes and the ready-use magazine above the gun itself) on each side, the total of 120 being sufficient for 15 or 20 engagements.

Bofors particularly emphasizes a new servo system that greatly reduces aiming errors and damping time, for greater accuracy when engaging air targets. Compared to the earlier Mk 1 (see below), Mk 2 uses a special monobloc steel barrel that does not require water cooling, and the turret of Mk 2 has a reduced radar cross section (10-20% lower than that of the earlier mount).

This weapon is used on board Swedish corvettes (*Spica-III* class) and has been selected for the Canadian "City"-class frigates.

Mk 1 is a less sophisticated version, for offshore-patrol vessels, coast guard vessels, etc. In Swedish service Mk 1 arms *Hugin*-class missile boats and *Spica*- and *Spica-II*-class missile boats. Mk 1 is also used by the Malaysian and Yugoslav navies. The rate of fire is 200 rnds/min, and elevation limits are +78/-10 deg (training rate 55 deg/sec, elevation 20 deg/sec). Am-

munition capacity is 128 rnds plus 40 ready-use rnds in the dual hoists.

Work on the 57/70 began in 1972, based largely on experience with the earlier 57/60. The major improvements were a higher rate of fire (200 vs. 130 rnds/min), the use of new ammunition with proximity and/or impact fuzes, an improved water-cooling system for the gun tubes, reduced weight (by using light alloys more extensively), and a new electro-hydraulic system for rapid slewing and elevation.

Reviewing this weapon, the U.S. Navy's Foreign Ordnance Review Team considered the 57/70 Mk 2 heavy compared to the OTO-Melara 35-mm and 76-mm weapons.

◆ Bofors 40-mm L70/Trinity

Caliber: 40-mm/70 **Rate of Fire:** 300 or 330 rnds/min
Muzzle Velocity: 1005–1025 m/sec [3300–3360 ft/sec]
Effective Range: 4000 m [4400 yd]
Training Rate: 85 deg/sec (elevation 45 deg/sec)
Elevation/Depression: +90°–10 deg
Weight: 2.8, 3, or 3.3 tons without ammunition

This weapon was conceived by Bofors to replace the World War II L60 gun. In various forms the 40-mm/70 has been in production since the late 1940s. All current production versions are single air-cooled guns. The current versions are SAK 40L/70-315, which is hand-operated; SAK 40L/70-350, which is power (electro-hydraulic) operated, gyro-stabilized, and remotely controlled; and SAK 40L/70-600, which employs the Trinity 99-rnd magazine (2 more rnds are in the intermediate feed position and in the ramming position). All 3 versions employ open-topped shields (for which GRP weather covers are available), the -600 version (Trinity) being recognizable by its special magazine. All of the Bofors-built 40-mm guns, then, use gravity-feed magazines directly descended from those of the earlier World War II Bofors 40-mm/60.

The Bofors 40-mm/70 with a Trinity 99-rnd magazine. (Bofors)

In August 1986 the West German navy awarded Bofors a contract to upgrade the existing German 40-mm/70 guns, using the new high-capacity magazine and elevating mass that had been developed for the Trinity (-600) version of the gun. The modernized guns have a higher rate of fire. Ships involved include the Type 343 minesweeper and the Type 148 missile attack boat.

The Royal Navy planned single-, twin-, and 6-barreled versions of the 40-mm/70, but all were canceled in 1957 in favor of the Sea Cat missile; the gun was used by the British Army. Projected British naval designations were Marks 10, 11, and 12, respectively.

Breda has produced the Bofors 40-mm/70 under license since 1969. The company has specialized in automatic loading mechanisms, which are described under the entry for the Breda Twin Fast Forty, above. The Breda 144-rnd automatic feed system is also manufactured under license by Empresa Nacional Bazan of Spain, for the Spanish navy.

Bofors has developed a variety of ammunition. The 40-mm/70 originally fired either armor-piercing (AP) or high-explosive with tracer (HE-T). Bofors developed the first production prox-

Trinity test-firing on board the Swedish minehunter *Landsort*. The small objects to either side of the gun mount are Elma ASW launchers. (Bofors)

imity fuze for a 40-mm shell, for the L70 gun, beginning large-scale production in 1975 (40-mm proximity fuzes are also manufactured by Borletti in Italy and by Thomson-CSF in France). Bofors has recently developed a similar fuze for the older 40-mm/60, many of which are still in service. In 1982 the company announced a proximity-fuzed prefragmented HE (PFHE) shell to deal specifically with low-flying aircraft and sea-skimming missiles. The shell contains 650 carbide-tungsten pellets, each of which can penetrate 14 mm of duraluminum. They surround the core of octol (HMX/TNT) explosive and are projected outward when it bursts. The steel body of the shell itself produces another 2400 fragments. The shell body is boat-

EFFECT AGAINST SEASKIMMING MISSILE.
KILL PROBABILITY AS A FUNCTION OF LAST INTERCEPT RANGE (M).
MISSILE ALTITUDE=5M. MISSILE SPEED 300 M/S. ACCELERATION=0.16.
TIME FOR TARGET MOVE RELATIVE TO THE FIRING
OF FIRST ROUND=0. (MOST DIFFICULT CASE.)
TRINITY FIRING WITH OPTIMIZED BURST PATTERN.
TIME OF FIRE 2 SEC.

— 30 MM APDS CIWS
- - - 40 MM TRINITY
... 20 MM APDS CIWS

Bofors' argument in favor of proximity-fuzed antimissile ammunition. This is the company's estimate of missile kill probability as a function of last intercept range, in meters, assuming a missile altitude of 5 m and a speed of 300 m/sec. It is assumed that the gun fires a 2-sec burst. The closer the kill, the more likely it is that fragments of the missile hit the ship. The dashed line on the right is for Trinity; the full line is for a 30-mm CIWS like Goalkeeper, and that below it is for a 20-mm CIWS such as Phalanx. (Bofors)

Trinity in a "stealth" mounting. (Bofors)

tailed for optimum splinter spread. Lethal radius is 6.5 m against aircraft and 4.5 m against missiles. Bofors argues that such a shell is more effective than a penetrator such as that used by the Phalanx or Goalkeeper systems, because the PFHE shell has a better chance of destroying an incoming missile. Although the overall rate of fire of the 40-mm/70 is much lower than that of a Gatling gun, Bofors argues that 1 of its shells is broadly equivalent to a burst fired by the Gatling.

TRINITY

PRINCIPLE FOR GAS JET CORRECTABLE AMMUNITION SYSTEM

Proposed 40-mm course-corrected shell. (Bofors)

The PFHE shell uses a doppler proximity fuze with special ECCM features; the shell can also explode on impact. Bofors claims that a 10-rnd PFHE burst is as effective as 50–75 rnds of HE-T. In theory, the doppler feature prevents the shell from bursting prematurely when it nears the sea surface.

There is also a high-capacity HE round (HCHE) using a point delay fuze, which allows the shell to penetrate a target for 0.3 msec (equivalent to 20 mm of armor) before bursting. Bofors claims that the large charge inside its HCHE shell provides blast effects equivalent to those of a conventional 57-mm shell.

An Italian firm, SNIA BFD, has developed an armor-piercing fin-stabilized discarding sabot (APFSDS) 40-mm shell, and this company has also developed a preformed fragmentation (PFF) round.

Bofors is currently developing a course-corrected 40-mm shell, which the company is convinced will be needed to deal with next-generation targets. The shell would carry enough propellant to allow several corrections in sequence, on the basis of command signals. Such a shell would have to be somewhat heavier (hence slower) than the Trinity 3P shell (see below), but Bofors argues that course correction would make up for any reduction in initial accuracy caused by lengthier time of flight.

The new 40-mm 4P GJC (gas-jet controlled), course-corrected shell was tested for the first time (against static targets) late in 1989. It is controlled by a radio link from the Trinity FCS. Using a 6-gas-jet auxiliary propulsion system, it can make several corrections in flight. Fins at the base of the shell reduce its spin rate to make corrections more effective. An entire 5–10-rnd burst can be shifted about 50 m. The command link can also set (delay) the proximity fuze so that a shell can penetrate a target.

Trinity is a modernized 40-mm/70 gun, conceived primarily as a close-in antimissile weapon, competing with systems such as Phalanx. As with Phalanx, the fire-control radar is mounted directly with the gun. The Bofors view was that, rather than rely on bursts of small-caliber projectiles, it would be better to use smaller numbers of larger-caliber ones, which would have predictable trajectories, and each of which would have much greater lethal effect. The company also determined that any future close-in gun would have to achieve much greater range than existing weapons. Work began about 1982, and Trinity was announced at Farnborough in 1984. Initial tests were conducted in 1985–86.

The name Trinity is derived from the synergistic combination of ammunition, weapon, and fire control.

Bofors argues that 40-mm is very nearly the ideal caliber for such a weapon since that size makes for a larger and hence much more lethal shell than the 20–35-mm weapons in use elsewhere; yet 40-mm can be fired much faster than the next natural size, 57-mm. Trinity's development began with an improvement in the ammunition. Higher-energy propellant was used to slightly increase muzzle velocity while increasing projectile weight by 25%. The new 3P shell weighs 1.1 kg (compared to 0.88 kg for the earlier PFHE and 0.96 kg for the old HE-T) and is slightly longer, for better aerodynamics. Explosive content is about 25% greater than that of the PFHE; upon bursting, the 3P produces more than 3000 fragments, including 1000 tungsten-alloy pellets. The weight of a complete round is 2.8 kg, compared to 2.4–2.5 kg for older 40-mm/70 rnds. Because the new shell is much more energetic than the older ones, the gun must absorb greater recoil forces; it uses a muzzle brake.

The fuze is programmable: it can be set, as it enters the breech, for proximity or point detonation. The burst pattern can also be preset: for example, a circular pattern to attack a high-altitude airplane or a fan pattern against a sea-skimming missile. The FCS is designed to position a 10-rnd burst around a missile, the pattern measuring 15–20 m across, with each fuze programmed individually during firing so that the pattern can be arranged to keep the lower rounds from triggering off the sea. Trinity can also fire a new AP shell.

There is a new high-capacity (99-rnd) magazine, holding 45

rnds to the left and 54 to the right of the gun, in 11 vertical rows. This division allows the gun to carry 2 kinds of ammunition at the same time. Only 1 side is used at a time, its outer row being emptied first. Typically, the gun carries 101 rnds, 99 in the magazine and 2 in the gun. Bofors assumes that the gun will typically fire 5–15 rnds per engagement. The gun is rated at 330 rnds/min, and claimed dispersion is 0.7 mrad.

The mounting as a whole is largely nonmagnetic since Swedish minesweepers are a major likely application. Elevation limits are +80/–20 deg, and the working circle radius is 2.974 m [117 in]. Total weight is 3700 kg [8155 lb].

The Trinity mount incorporates a specially built Bofors microprocessor, a radar, a laser range-finder, a gyro-stabilized reflex sight, and an image intensifier for night operation. The computer determines the number of rounds to be fired, the fuze setting, the programmed burst pattern, and the actual moment of firing for greatest effect. As of mid-1990, it still was not certain whether the radar would be the Ericsson Ku-band Eagle or the BEAB Ka-band radar, which had been preferred earlier.

Claimed effective range is 2000–3000 m against a low-flying fast attack airplane, or 2500 m against a sea-skimming missile.

A remotely controlled version, Trinity Spartan, has also been designed; it incorporates the same ammunition and weapon, but the fire control is off-mount. Bofors conceived Trinity as an integrated system using its own sensors. However, the company has also offered to combine Trinity with existing fire-control radar systems, such as that employed in the Dutch Goalkeeper.

Trinity was tested on board the Swedish minesweeper *Land-sort* in the winter of 1988. Trinity was to be integrated with a new Ericsson Eagle coherent-doppler tracking radar.

Trinity was first demonstrated in public in September 1988. Sea Trinity was shown engaging a helicopter hovering behind a curtain of trees at 2600-m range, then firing bursts against a simulated maneuvering target, then firing against armored containers. The gun then fired a burst of 8 rnds, each set for a different mode (to demonstrate the programmability of the 3P round); and then the gun fired 100 rnds against a target container at 1100-m range.

In 1988 the Swedish Defense Procurement Administration commissioned Bofors to study a "stealth" version of Trinity, for use on board a future warship. Trinity is already shaped to reduce its overall radar cross section and incorporates radar-absorbing material to cover openings and cavities. The gun also has a low magnetic signature, and Bofors claims that the basic design allows for further signature reduction by computer-controlled active compensation. A sketch released at the time shows the basic Trinity enclosed within a cupola with flat sides angled inward to reduce radar reflections.

Trinity was first ordered, for the Swedish navy, in May 1990 to arm the new Swedish stealthy surface-effect ship. Plans initially called for the gun to retract into the deck, but the planned elevator was not rigid enough, and the gun mounting was considered stealthy enough to be left above decks.

◆ Bofors 40-mm (old types)

Caliber: 40-mm/60 (barrel length is actually 56 calibers) (0.9-kg [1.98-lb] shell) **Rate of Fire:** 120 rnds/min
Muzzle Velocity: 800–880 m/sec [2620–2890 ft/sec]
Maximum Range: 10,000 m; effective range 3000 m [10,900/3300 yd]
Elevation/Depression: +90/–5 deg
Ammunition Capacity: 4-rnd clip

The Bofors 40-mm/60 was the standard Allied heavy automatic anti-aircraft gun of World War II, remaining in service in some numbers, both in single and in twin mounts. See the British and U.S. sections, below, for details of their 40-mm mounts. Postwar, Bofors developed a higher-velocity 70-caliber gun, which was adopted by many navies. Breda developed a series of automatically fed 40-mm/70s (see Italian entries above).

The original Bofors guns all used 4-rnd clips that were gravity-fed into the gun from above. All subsequent Bofors 40-mm and 57-mm guns continue to use the same basic gun mechanism,

which is fed from above. Land-based (and some single naval) versions were air-cooled; naval twins were all water-cooled.

Bofors currently offers a variety of modernization options for the 40-mm/60. Although generally described in connection with land-based guns, these options are applicable to surviving naval units. Bofors claims that the effect of modernizing the 3 main components of the weapon—the gun itself, its sight, and its ammunition—improves kill probability against a typical fighter-bomber by 50–80% (e.g., kill probability at 1 km rises from about 18 to nearly 100%), based on a 9-rnd burst. The gun's rate of fire is increased by about 50%, from 120 to 180 rnds/min; the hopper at the top of the gun is enlarged to hold 20 rnds (so that 2–3 targets can be engaged between reloadings; the rounds are still carried in clips of 4, for easy handling); and power laying is introduced (for guns on land; naval mountings are generally already power operated).

The earlier point-detonating ammunition is replaced by PFHE proximity rounds similar to those developed for the L70 gun (see above). Bofors claims that the effect of the proximity fuze is to increase the effective bursting area of the target (i.e., the probability that a shell will burst) by a factor of 50–300. Maximum bursting range is 5.5 m (reducible by automatic sensitivity control to 1–2 m for use against missiles flying at low altitude). Muzzle velocity is 860 m/sec [2820 ft/sec], and total shell weight is 980 g [2.16 lb], including 90 g of octol explosive. The gun is fitted with a proximity fuze disconnecter, so that the shells can still function in the point detonating mode if required. The disconnecter is attached to the front of the ammunition hopper atop the gun. The gun can also fire HET (high-explosive tracer; in this case HE means greater penetrating power rather than a high-explosive filling), PT, and APHC-T (armor-piercing high-capacity tracer) ammunition. The APHC-T shell is unusual in carrying a heavy armor-piercing slug within an aluminum shell body; Bofors claims that APHC-T penetrates 30% deeper than earlier armor-piercing capped tracer (APC-T) rounds. As a side benefit, the aluminum body should have an incendiary effect on the target.

A new gun-mounted "U-sight" system is added, incorporating a laser range-finder.

As modernized, the land version of the gun trains at 85 deg/sec and elevates at 50 deg/sec; dispersion is less than 4 mrad.

For other versions of the 40-mm/60, see the U.K. and U.S. guns below.

SWITZERLAND

◆ Oerlikon 35-mm (Type GDM-A)

Caliber: 35-mm/90 **Rate of Fire:** 1100 rnds/min
Muzzle Velocity: 1175 m/sec [3850 ft/sec]
Effective Range: (air/surface) Radar Control: 5000/8000 m [5500/8700 yd] Optical Control: 2500/5000 m [2700/5500 yd] Local Sight: 3000/5000 m [3300/5500 yd]
Training Rate: 120 deg/sec (elevation 130 deg/sec)
Elevation/Depression: +85/–15
Ammunition Capacity: 336 rnds
Weight: 10,500 lb without ammunition
Working Circle: 4716 mm [185.7 in]

Unlike the British BMARC/Oerlikon GCM, this weapon is clip-fed, with 112 rnds of ready-use ammunition and another 224 rnds carried within the mount. The guns can be reloaded while they fire. GDM-A is electrically controlled and biaxially stabilized, and the gun has a stabilized sight and joystick for local control. The gun can also be manually controlled in an emergency.

The GDM-C version was developed jointly with OTO-Melara, using the same Type-KDC gun. A U.S. Navy Foreign Ordnance Review Team concluded about 1971 that the OTO-Melara version, described as an updated GDM-A, was better suited to U.S. requirements. The users are Iran (1 mount aft on the single Mk-7 frigate) and Greece (2 each on 4 missile boats).

The Japanese Maritime Self-Defense Agency uses a single version of this gun, with a sidecar for the operator.

The Oerlikon twin 35-mm gun (GDM-A). (Oerlikon)

The Oerlikon twin 35-mm gun (GDM-C), developed in collaboration with OTO-Melara. (Oerlikon)

◆ Oerlikon 30-mm

See United Kingdom BMARC-Oerlikon 30-mm below.

◆ Sea Zenith (Type GBM-B1Z)

Caliber: 25-mm/92 **Rate of Fire:** 850 rnds/sec
Muzzle Velocity: 1335 m/sec [4380 ft/sec]
Training Rate: 2.5 rad/sec (elevation of 2.5 rad/sec) [143.2 deg/sec]
Elevation/Depression: +127/–14 deg
Ammunition Capacity: 415 rnds/gun
Weight: 4600 kg plus 2150-kg ammunition feed system [10,140/4740 lb]

Sea Zenith is the 4-gun weapon associated with the Swiss Contraves Seaguard system (see above under shipboard radars and FCSSs). The guns are designated KBB-R03/L03. The ammunition supply is sufficient for 18 engagements, and the guns can be reloaded while they fire.

The unusual elevation arc makes it easier for the gun to engage very high targets; that arc is achieved by having the gun train in a plane canted at a 35-deg angle.

The Oerlikon 30-mm twin manned antiaircraft gun (GCM-A03-1). The A03-2 version has provision for local control (the sidecar lacks a wind-shield) but can also be remotely controlled. A03-3 is entirely remotely controlled. (Oerlikon)

◆ Oerlikon 25-mm (Type GBM Diane Navale and GBM-A01)

Caliber: 25-mm/80 **Rate of Fire:** 600 rnds/min/gun
Muzzle Velocity: 1100–1360 m/sec [3600–4460 ft/sec]
Training Rate: 1.4 rad/sec (elevation of 0.85 rad/sec) (80.2 and 48.7 deg/sec)
Elevation/Depression: +80/–20 deg
Ammunition Capacity: 500 rnds
Weight: 2300 kg (1900 kg without ammunition) [5070/4190 lb]

This naval version of the towed twin 25-mm gun was announced at Mostra Navale 1984. The mount can carry either the KBA gun (data given) or the more powerful KBB of the Sea Zenith. In a low-recoil version, KBA can also be used as a helicopter gun.

The KBA gun can also be carried in a GBM-A01 single manual mount; Oerlikon describes GBM-A01 as the most powerful available manually operated gun mount. Ammunition capacity is 140 rnds (two 70-rnd boxes), and elevation limits are +55/–10 deg. Cyclic rate is reduced to 570 rnds/min. Total weight, including ammunition, is 600 kg [1320 lb]. The boxes can be enlarged to carry 100 rnds each. This mount is no longer in production.

◆ Oerlikon 20-mm (Type GAD-A0A)

Caliber: 20-mm/85 **Rate of Fire:** 1000 rnds/min
Muzzle Velocity: 1100–1200 m/sec [3600–3940 ft/sec]
Elevation/Depression: +70/–12 deg
Ammunition Capacity: 100 rnds
Weight: 1055 kg including ammunition [2325 lb]
Working Circle: radius 2755 mm [108.5 in]

This turreted belt-fed 20-mm single-operator cannon (Type KAA, formerly known as 204GK) was designed for patrol craft, e.g., the Austrian Danube gunboat. GAD-A0A was manufactured under license by BMARC, reportedly for a Commonwealth customer. The mount probably dates from the late 1960s, BMARC announcing its version in 1977.

◆ Oerlikon 20-mm (Type GAM-B01)

Caliber: 20-mm/85 **Rate of Fire:** 1000 rnds/min
Muzzle Velocity: 1050 m/sec [3440 ft/sec]
Maximum Range: 2000 m [2200 yd]

Elevation/Depression: +55/–10 deg
Ammunition Capacity: 200 rnds
Weight: 92 kg without ammunition (90 kg of ammunition) [203/198 lb]

This manual mount carries a KAA cannon. Arming many fast attack craft, the 20-mm cannon is mounted on board most British warships as a result of the Falklands emergency. This cannon is manufactured in Britain by BMARC under the designation A41/820. The Royal Navy uses the GAM-B01 designation.

This cannon is essentially equivalent to the World War II Oerlikon 20-mm gun, with a higher muzzle velocity.

Oerlikon 20-mm single mount as selected by the Royal Navy (GAM-B01). (Oerlikon)

◆ Oerlikon 20-mm (Type GAM-C01)

Caliber: 20-mm/95 **Rate of Fire:** 900 rnds/min
Muzzle Velocity: 1050–1150 m/sec [3440–3770 ft/sec]
Elevation/Depression: +55/–10 deg
Ammunition Capacity: 200 rnds

This weapon is very similar to GAM-B01 but is a Hispano-Suiza 820 (now designated KAD-B13-3 by Oerlikon). Like the other mount, GAM-C01 was manufactured by BMARC as well as by Oerlikon itself. BMARC developed the new pedestal mount in 1968–70 as a private venture; production began in 1970.

◆ Oerlikon 20-mm (Type A41A)

Caliber: 20-mm **Rate of Fire:** 800 rnds/min
Muzzle Velocity: 835 m/sec [2740 ft/sec]
Elevation/Depression: +50/–10 deg
Ammunition Capacity: 58 rnds
Weight: 225 kg [496 lb]
Working Circle: 1.7 m [66.9 in]

Type A41A, with its ammunition drum, is the closest current equivalent to the World War II Oerlikon. The other current Oerlikons are belt-fed from a rectangular box on the front of the mount.

The gun is the Hispano-Suiza HS804, originally designed for aircraft use and having, therefore, a very low recoil force. A41A was dropped from the Oerlikon line but revived about 1980 because some customers liked its simplicity, ease of handling, and reliability.

This weapon has been manufactured both by Oerlikon and by BMARC.

◆ Oerlikon (Old Type)

See the U.S. entries below for details of typical World War II Oerlikon 20-mm cannon, which are still used by many navies.

USSR

The Soviets either have discarded or are discarding their *Sverdlov*-class cruisers and "Kotlin"- (and "Kotlin" derivative) and *Skoryy*-class destroyers. The following weapons have, therefore, been eliminated from this edition (details can be found in the previous edition of this book): the 6-in/57 B-38, the 130-mm/50, and the 45-mm. Descriptions of the 85-mm and 45-mm guns have been retained because they remain in PRC service.

◆ 130-mm/70

Muzzle Velocity: 1000 m/sec
Maximum Rate of Fire: 65 rds/min/mount
Maximum Range: about 28,000 m
Elevation/Depression: +85/-15 deg

This fully automatic dual-purpose weapon was introduced in the *Sovremennyy* class and is also mounted on board *Slava*-class cruisers and the *Frunze*. 130/70 may be triaxially stabilized. The barrels are liquid-cooled.

The associated fire-control radar is Kite Screech. The mount also has local controls.

A twin 130-mm gun on board the cruiser *Marshal Ustinov* at Norfolk, 1989. (S. Zaloga)

◆ 130-mm/58

Caliber: 5.1-in/58 (33.5-kg shell with 20-kg cartridge)
Rate of Fire: 15 rds/min/barrel (max)
Muzzle Velocity: 945 m/sec [3100 ft/sec]
Maximum Range: 28,000 m [surface]; 16-18 thousand (effective) [30,600/17,500-19,700 yd]
Elevation/Depression: +85/-5 deg **Weight:** approx 60 tons

Twin 130/58 mount on board a Chinese Luda-class destroyer. (U.S. Naval Institute)

This standard postwar, triaxially stabilized, dual-purpose, semiautomatic gun is installed on Kotlin-class destroyers. The gun is designated 56-SM, and the mount may have been derived from the wartime German 128-mm fully stabilized antiaircraft weapon. This gun and mount are currently manufactured in China (PRC), the Chinese version differing from the Soviet by lacking mechanical cross-level stabilization; the edges of the Chinese gunhouse are rounded, and the gun lacks the range-only radar of Soviet mounts.

The associated fire-control radars are Sun Visor and Post Lamp or Half Bow (Wasp Head director). All mounts originally incorporated Egg Cup range-only radars, but they have gradually been discarded.

◆ 115-mm

Caliber: 115-mm/55
Muzzle Velocity: 780 m/sec (HE-frag shells) [2560 ft/sec]
Maximum Rate of Fire: 4 rds/min
Elevation/Depression: +17/-4 deg
Maximum Range: 4800 m [5250 yd]

This tank gun is installed in Yaz-class river monitors. Figures above are for the U-5 TS gun as carried by the T-62 tank.

◆ 100-mm

Caliber: 100 mm/70 **Rate of Fire:** 80 rds/min
Maximum Range: 15,000 m (effective range 8000 m) [16,400/8700 yd]

This is the automatic single-barreled water-cooled mount on *Kirov*, *Udaloy* class, and *Krivak-II* and *-III*. It has optronic analog controls.

A single 100-mm gun on board the *Udaloy*-class destroyer *Admiral Vinogradov*, 1990, with its Kite Screech control radar in the background. (S. Zaloga)

◆ 100-mm/56

Caliber: 3.9 in/56 (15.6-kg shell, 28-kg fixed rnd) [34.4/62 lb]
Rate of Fire: 15 rds/min
Muzzle Velocity: 900 m/sec [2950 ft/sec]
Maximum Range: 16,000 m (effective range 10,000 m) [17,500/10,900 yd]
Elevation/Depression: +85/-5 deg
Weight: 13.5 tons (single mount)

This obsolescent single shielded mount is found on Riga-class frigates and Don-class submarine tenders. 100/56 was later manufactured in China. The original maximum elevation was 40 deg. This mount was formerly used as a secondary battery for cruisers and was modernized in 1947. Electrically driven, the gun can fire in automatic, local, or manual modes. The breech is a horizontal sliding block. A twin version was designed about 1940 for the abortive Soviet battleship program. China now manufactures an autoloading twin version (see above).

(Above) The Soviet 100-mm/56 mounted on board a Riga-class frigate, May 1984. The director is a Wasp Head, carrying a Sun Visor radar; and the main air-search radar is Slim Net. The guns aft are twin 37-mm, comparable to the old U.S. twin 40-mm Bofors. There are 4 torpedo decoys (of 2 types) on the fantail. The rocket launchers are RBU 2500s. (U.S. Navy)

The Soviet designation for the single mount is Bu-34. The associated director is Wasp Head with (in a few PRC ships) a Rice Lamp radar. Older Soviet ships used Cylinder Head to control this gun.

◆ 85-mm

Caliber: 85-mm/52 (9.6-kg shell, 13-kg fixed round) [20.9/28.7 lb]

Rate of Fire: 10 rds/min/barrel

Muzzle Velocity: 850 m/sec [2785 ft/sec]

(Below) Twin 76.2/60 guns arm this Mirka-class ASW corvette. There are torpedo decoys stowed on deck aft, 4 RBU-6000 rocket launchers, and 40-cm torpedo tubes. (U.S. Naval Institute)

Maximum Range: 15,000 m (effective range 8–9 thousand surface, 6000 m air) [16,400/8700–9800 yd]

Elevation/Depression: +75/–5 deg (maximum 85 deg in single version)

Weight: 5.5 tons (single)

This obsolescent twin mount survives on unmodified *Skoryy*-class destroyers. A single mount (maximum elevation 85 deg, elevation rate 8 deg/sec) is used by the PRC and other communist navies, arming smaller craft such as *Kronstadt*-type subchasers. The reported Soviet designation is 90K (twin mount HAM 39-3).

The modernized single mount (in use since 1948) is manually driven under local control. The twin mount is electrically driven; ammunition supply through the mount limits elevation to 75 deg.

◆ 76.2-mm/60

Caliber: 3-in (6.8-kg shell, 16-kg fixed round) [15/35 lb]

Rate of Fire: 45 rnds/min/barrel

Muzzle Velocity: 900 m/sec [2950 ft/sec]

Maximum Range: 15,000 m (effective at 11,000 m; effective for anti-aircraft at 6–7 thousand m)

Elevation/Depression: +85 deg

Ammunition Capacity: 43 (per barrel)

Weight: approx 25 tons (rotating mass)

The caliber is 3-in, not 76-mm. This weapon is installed on board *Kara*- and *Kynda*-class cruisers; *Kashin*-class destroyers; *Krivak*-I-, *Koni*-, *Petya*-, and *Mirka*-class frigates; *Smoln'nyy*-class training ships; and *Ivan Susanin*-class icebreakers. The 76.2/60 was introduced in 1961. The mount is semiautomatic, like the U.S. twin 3-in/50; rounds are hoisted 43 at a time (per barrel) into the gunhouse. The gun is not water-cooled, but standard practice is to use a fire hose to cool down the barrel after an engagement. The turret has an unusually deep cleft, so the guns can be mounted aft of the center of the trunnion, for

Two Shmel-class gunboats, probably on the Amur, show their tank-type 76.2-mm guns. The guns aft are machine guns; later ships of this type have the standard twin 25-mm (over and under) mount. (TASS via SOVFOTO)

A Tarantul-class missile boat of the Soviet Baltic Fleet fires her single 76.2-mm gun. The radome atop her mast is Light Bulb, probably a missile data link. Below it is a Bass Tilt fire-control radar, and the big radome is Band Stand. The missiles are SS-N-2Cs. (TASS via SOVFOTO)

a high angle of elevation. The associated fire-control radars are Hawk Screech and Owl Screech.

◆ 76.2-mm/60 Single Mount

Caliber: 3-in/60 **Rate of Fire:** 120 rnds/min

Maximum Range: 14,000 m surface; 6–7 thousand m (air target) [15,300/6600–7700 yd] **Elevation/Depression:** +85 deg

This automatic single mount, with on-mount crew, is found on Grisha-V- and Parchim-II-class light frigates; Nanuchka-III-, Pauk-, and Tarantul-class corvettes; Matka-class missile hydrofoils; and the 1 Slepenskiy-class patrol boat.

The associated fire-control radar is Bass Tilt.

◆ 76.2-mm/55 Single Mount

Caliber: 3-in/55 (6.6-kg shell, 11.2-kg fixed round) [14.6/24.7 lb]

Rate of Fire: 17–20 rnds/min

Muzzle Velocity: 815 m/sec [2675 ft/sec]

Maximum Range: 13,500 m [14,600 yd]

Elevation/Depression: +85 deg **Weight:** approx 5 tons

This weapon was introduced in the Soviet Navy in 1936 but is now used only by North Korea. The shield is similar to that of the Soviet 85-mm gun (90K), and the 76.2 Single Mount uses a vertical sliding-block breech.

◆ 76.2-mm/48 Single Mount

Caliber: 76.2-mm/48

Muzzle Velocity: 680 m/sec [2230 ft/sec] (HE shell)

Maximum Rate of Fire: 4–6 rnds/min (claimed 15 rnds/min max)

Elevation/Depression: +30/–4 deg

Maximum Range: about 800 m effective range, point-blank [about 870 yd]

The PT-76 tank turret gun (D-56TM) is found in Shmel-class river monitors.

◆ 57-mm (twin automatic mount)

Caliber: 57-mm/80 (2.7-kg shell, 5-kg fixed round) [6/11 lb]

Rate of Fire: 120 rnds/min/barrel

Muzzle Velocity: 1000 m/sec [3280 ft/sec]

Maximum Range: 12 km horizontal, 6.7 km vertical [13,100 yd/22,000 ft]; effective ranges about 9000 m horizontal, 5–6 thousand m vertical [9800 yd/16,400–19,700 ft]

Elevation/Depression: +90/–10 deg

Weight: 25 tons (without ammunition)

This fully automatic mount is found on *Moskva*, *Kresta*-I and -II, *Poti*, *Grisha*, *Nanuchka*-I, *Turya*, *Ropucha*, *Urga* classes, etc.

Twin automatic 57-mm guns on board a *Moskva*-class helicopter carrier, with a Head Lights SA-N-3 fire-control radar visible above the bridge. The small navigational radar below it is Don-2. [U.S. Navy]

The barrels are water-cooled. The 57-mm first entered service in 1963. Unlike the various forms of ZIF-31B, this mount is fully enclosed, with a metal shield; ammunition supply is presumably fully automatic. Control is generally by a Muff Cob radar director. In some classes, later units have the newer 76.2-mm/60 in place of this weapon.

The Soviet designation is ZIF-72 (the Indian navy reports an AK-257 designation for the mount on its frigate *Ganga*).

57-mm/80 Soviet-type twin mount on board the Indian frigate *Ganga*. The mount is designated AK-725 in Indian service. (*Ships of the World*)

◆ 57-mm Antiaircraft Gun

Caliber: 57-mm/70 (2.8-kg shell, 6.3–6.6-kg round) [6.2/13.9–14.5 lb] **Rate of Fire:** 120 rnds/min/gun
Muzzle Velocity: 1020 m/sec [3350 ft/sec]
Maximum Range: 4500 m vertical [14,700 ft]
Training Rate: 30 deg/sec (elevation 25 deg/sec)
Elevation/Depression: +90/0 deg
Weight: 28,000 kg quadruple mount; 6000 kg single mount; 14,500 kg twin mount [61,700/13,200/32,000 lb]

This weapon exists in single (e.g., modified *Skoryy* class), twin, and quadruple (Kanin, Kildin classes) forms. In the quadruple mount the guns are in superimposed pairs. This weapon entered service in 1958 and was a navalized version of the 57-mm/70 M-50 used by the Soviet army. That gun in turn was developed from a 55-mm antiaircraft gun under development in Germany late in the Second World War.

Like earlier Soviet naval antiaircraft guns, this one loads from clips. Heating and clip-feeding would probably limit its effective rate of fire to 90 rnds/min. The associated fire-control radar is Muff Cob.

Quadruple 57-mm guns on board a Krupny-class missile destroyer. The mast radomes are presumably a pair of Top Hat jammers with the associated Bell-series ESM above. (U.S. Navy)

The Soviet designation is ZIF-31B.

The PRC navy uses a water-cooled version of this weapon, designated Type 76. Muzzle velocity is 1000 m/sec [3280 ft/sec], and maximum horizontal and vertical ranges are 15,000 and 10,000 m. Rate of fire is 140–160 rnds/min, and elevation limits are +85/–5 deg. Maximum laying speeds are 25 deg/sec both in train and in elevation, but the mount can sweep (i.e., can move less precisely) at 40 deg/sec both in train and in elevation. Total mount weight is 10,500 kg [23,140 lb]. No working circle data are available, but the mount's length is 6.583 m and width is 3.36 m (height is 2.264 m).

◆ 37-mm

Caliber: 37-mm/63 (0.74-kg shell, 1.8-kg round) [1.6/4.0 lb]
Rate of Fire: 160 rnds/min/gun twin; 130 rnds/min/gun single
Muzzle Velocity: 880 m/sec [2890 ft/sec]
Maximum Range: 9500 m [10,400 yd]
Training Rate: 20 deg/sec (elevation 15 deg/sec); powered mounts
Elevation/Depression: +85/0 deg
Ammunition Capacity: 5-rnd clips
Weight: 6170 lb single mount, 8375 lb twin mount

Soviet single air-cooled 37-mm/63 gun. (TASS from SOVFOTO)

This obsolescent prewar weapon is found in twin mounts on board some *Sverdlov*-class cruisers, *Skoryy*-class destroyers, Riga-class frigates, and T-43-class minesweepers. There was also a single mount, now extinct in Soviet service. The single guns were air-cooled, with the usual Bofors-type recoil springs surrounding the bases, and barrels had to be changed after about 100 rnds. The twin mount, introduced in 1948, is similar in layout to the standard U.S. twin 40-mm of the time, with liquid-cooled guns. Loading is by 5-rnd clip. The Soviet designations are 70-K for the original single mount, V-11M for the initial-production twin naval mount, and V-47M for later twin mounts with water-cooled barrels. It appears that V-47M was the widely used postwar version. A quadruple version was begun in 1939–40 but appears not to have entered service.

This gun is derived from a Bofors 25-mm gun of 1933, sold to the Soviet Union some years later. Because the 25-mm gun was very similar in design to the Bofors 40-mm of 1934 (the ancestor of the standard World War II 40-mm gun), the 37-mm is very similar to the Bofors 40-mm/60, with different ancestry. The 37-mm fires ammunition derived from the Colt-Browning 37-mm, which was inferior to the contemporary Bofors 40-mm rnd. This weapon was developed in preference to a turreted twin 45-mm automatic gun, on which work began in 1937–38.

This mounting is standard in the PRC navy in both single and twin mounts. The mount was produced in China, but without the cross-stabilization standard in many Soviet mounts.

Soviet twin liquid-cooled 37-mm/63. (TASS from SOVFOTO)

◆ 30-mm Gatling

Caliber: 30-mm/65

Rate of Fire: 3000 rnds/min/mount (probably 1000 rnds/min effective rate)

Muzzle Velocity: 1000 m/sec [3280 ft/sec]

Maximum Range: 2500 m (maximum altitude probably 500–600 m) [2700 yd; 1640–1970 ft]

Elevation/Depression: +90/–10 deg

This 6-barreled Gatling gun has a mount similar to that of the twin 30-mm weapon. The 30-mm Gatling, generally con-

A 30-mm Gatling gun on board the cruiser *Marshal Ustinov*, 1989. (S. Zaloga)

trolled by Bass Tilt or by a remote Kolonka-II visual director, is the standard current Soviet close-in defensive weapon.

The designation ADMG-630, which frequently appears, is a NATO rather than a Soviet name (Air-Defense Machine Gun 6 × 30). The Soviets probably call the gun AK 630. It first appeared in the summer of 1970.

◆ CADS-1

The cruiser *Kalinin*, the third unit of the *Kirov* class, completed in 1989, carries a new close-in weapon in place of the AK 630 of earlier units of this type. Each mounting carries a pair of guns under paired missile launchers. The missiles are paired vertically or horizontally, in different mountings; these alternatives are probably being compared to see which provides the least mutual interference.

A large radar antenna occupies the center of the mount, flanked on the right by a similar but smaller antenna. Each is much higher than it is wide, producing a beam narrower in the vertical than in the horizontal. That configuration might be extremely desirable for a system intended to detect and track low-flying missiles, postponing the onset of multipath problems. The combination of very similar large and small radar antennas in Soviet naval practice is generally associated with command guidance, and in this case there is a small dish (presumably to transmit the commands) between the 2 main radars. The left side of the mounting carries what appears to be an electro-optical device, possibly a television tracker or a laser, and there are small radomes on the lower part of the mounting. Other navies find a television or IR tracker very useful in avoiding multipath problems when engaging low-altitude targets (such as sea-skimmers).

The combination of guns with missiles on the same mount recalls the Soviet army 2S6 self-propelled antiaircraft weapon, which appeared in 1986 and is now replacing the earlier ZSU 23-4 quadruple mount. The 2S6 carries 2 twin 30-mm cannon and SA-19 missiles, 4 on either side. The cannon are part of a new family of weapons that includes the 2A42 cannon of the new BMP-2 armored personnel carrier; this weapon fires HE-T and AP-T ammunition at the rate of 200–300 or 500 rnds/min. In this case maximum vertical range is 5000 m, and effective antiaircraft range is 3000 m. Other members of the new gun family arm the Hind-E assault helicopter, the Su-25 Frogfoot ground-attack fighter, the MiG-29, and the Su-27 Flanker. In the case of the antiaircraft tank, the missiles are reloaded in clips of 2, and are probably launched in pairs. Estimated range is 7–10 km. The army version of the system probably carries a mixture of IR and command-guided missiles.

The new naval system differs substantially from the army's 2S6. Its guns seem shorter, and close-ups show that they are 30-mm Gatlings. They may use a new family of 30-mm ammunition now being introduced on Soviet army weapons.

The NATO designation, CADS, means Combined (i.e., gun/missile) Air-Defense System.

◆ 30-mm Twin Mount (AK 230)

Caliber: 30-mm/65 (0.54-kg shell, 1.0-kg round) [1.2/2.2 lb]

Rate of Fire: approx 1050 rnds/min/barrel (effective rate 200–240)

Muzzle Velocity: 1050 m/sec [3440 ft/sec]

Maximum Range: 4000 m [4400 yd]

Training Rate: 70 deg/sec (elevation 55 deg/sec)

Elevation/Depression: +100 deg

Ammunition Capacity: 100 ready use, 600 magazine

Weight: 3.5 tonnes without ammunition [7715 lbs]

This widely used light weapon is widely exported. The unmanned mount is fully enclosed, stabilized, and power-driven. The gun tubes are liquid-cooled, and the guns are gas-operated. This mount is normally controlled by a Drum Tilt radar or by a remote Kolonka-I optical director. The gun is a revolver, with a 4-rnd rotating breech.

AK 230 is the Soviet designation. This weapon appeared in 1959, as a successor to the earlier twin 25-mm. AK 230 is still in production, primarily for export.

The CADS-1 air-defense system is shown on board the Soviet cruiser *Kalinin*, 1988. It occupies the platform below, and to the left of, the Tin Man optronic sensor. Pairs of missiles and Gatling guns flank a nodding height-finder dish. (German MoD)

This weapon is produced in the PRC under the designation Type 69. Elevation limits of this version are $+87/-12$ deg, and the mount trains at 70 deg/sec and elevates at 50 deg/sec. Total weight is 1800 kg [3967 lb]; the weight figure above may include ammunition. Overall dimensions: $3.110 \times 2.100 \times 1.462$ m.

Soviet-type twin 30-mm gun mount on board the Indian frigate *Ganga*. (*Ships of the World*)

◆ 25-mm Twin Mount

Caliber: 25-mm/60 (0.25-kg shell, 0.7-kg rnd) [0.55/1.5 lb]
Rate of Fire: 450 rnds/min; effective rate 270–300 rnds/min (also given as 150–225 rnds/min/barrel)
Muzzle Velocity: 910 m/sec [2980 ft/sec]

Maximum Range: 3000 m; effective range 2300 m [3300/2500 yd]
Training Rate: 40 deg/sec (elevation 70 deg/sec) under hydraulic power (manual rates are 15 and 25 deg/sec, respectively)
Elevation/Depression: $+83/-10$ deg
Ammunition Capacity: 130 rnds **Weight:** 1.5 tons

Widely used for light craft, this weapon consists of 2 superimposed guns, with an on-mount optical sight. For ex-

Twin 25-mm anti-aircraft guns on board a P-6-type motor torpedo boat, about 1962. (TASS from SOVFOTO)

ample, this weapon arms Komar-class missile boats. It is still manufactured in China (PRC). The 2 machine guns are belt-fed from boxes on the left side of the mount, the gunner sitting on the right side. Guns are air-cooled, with prominent recoil springs around the bases. Normally, coupled 65-rnd belts are used, but the weapons can also be fed from 7-rnd clips.

This weapon is a Soviet version of the Bofors 25-mm, from which the 37-mm antiaircraft gun was developed. The Loginov design bureau, which was responsible for both weapons, actually concentrated on the 37-mm version (which entered production in 1939), and only in 1939 began to adapt the 25-mm version (Model 1940). Production began in September 1941. The twin-barreled naval version (2M-8) entered service in 1952; it was a heavily redesigned derivative of the army gun. The designation 2M-3 110PM has also been reported for this weapon.

The twin 30-mm mount (AK 230) was developed to replace this gun.

This weapon is produced in the PRC under the designation Type 61. The Chinese version has a maximum elevation of 85 deg. Total weight, including ammunition (65 rnds per gun), is 1735 kg [3824 lb]; overall length (at zero elevation) is 2.810 m, and maximum width is 1.974 m.

◆ 23-mm Machine Gun

Caliber: 23-mm/87 **Rate of Fire:** 1600 rnds/min/barrel
Muzzle Velocity: 970 m/sec [3180 ft/sec]
Maximum Elevation/Depression: +90 deg
Maximum Range: 3000 m (maximum altitude 2000 m) [3300 yd; 6600 ft]

This weapon appeared on board Pchela-class border patrol hydrofoils, all now retired, in a twin enclosed turret that resembles that of AK 230. This machine gun may survive on board river gunboats. It was introduced in 1965.

◆ ZU-23

Caliber: 23-mm/81
Rate of Fire: 1000 rnds/min/barrel (cyclic); effective rate 200 rnds/min/barrel
Ready-use Ammunition: 50 rnds/gun (box magazine)
Muzzle Velocity: 970 m/sec [3180 ft/sec]
Maximum Elevation/Depression: +90/-10 deg
Maximum Range: 7000 m; effective range 2800 m [7700/3000 yd]
Training Rate: manual **Weight:** 893 kg [1968 lb]

This twin-barreled army weapon is used by both the East German (e.g., on board *Libelle*-class light torpedo boats) and Polish (e.g., on board some *Krogulec*-class minesweepers) navies. It has replaced the Sea Cat launcher on board Iranian *Saam*-class frigates. The Indian government armed some of its merchant ships with this weapon during the Iran-Iraq War. The barrels are air-cooled.

◆ 14.5-mm Machine Gun

Caliber: 14.5-mm/93 **Rate of Fire:** 600 rnds/min/barrel
Ready-use Ammunition: 150 rnds/gun (linked belt)
Muzzle Velocity: 1000 m/sec [3280 ft/sec]
Maximum Elevation/Depression: +90/-5 deg
Maximum Range: 7000 m [7700 yd]

This light antiaircraft mount is no longer in widespread Soviet service but has been license-produced in China and serves on board Chinese Riga-class frigates, *Kronstadt*-type patrol vessels, *Huchuan*-class torpedo boats, and *T-43*-type minesweepers. This gun may no longer be in production. At one time it was described as a 12.7-mm machine gun; it replaced the earlier Degtyarev DHSK 38 12.7-mm gun on a 1-for-1 basis, beginning some time after 1945. The earlier gun used a 50-rnd metal belt and fired 300-500 rnds/min (0.043-kg bullets, muzzle velocity 814 m/sec [2671 ft/sec]).

The Soviet designation is 2M-7. In Soviet-made mounts the guns are superposed. The Chinese build a version in which the guns are side by side, e.g., in *Huchuan*-class hydrofoil torpedo boats. The Chinese version has been exported to Romania.

The PRC version is designated Type 82. It fires API (990 m/sec muzzle velocity) and API-T (tracer) (1000 m/sec) rounds.

Twin 14.5-mm machine guns forward, on board a Pchela-class patrol boat. Although this class has been discarded, the same mount is used on board the replacement Zhuk class. The radar is Pot Drum. (U.S. Naval Institute)

Effective range against air targets is 2000 m; against surface targets, 2200 m. Effective rate of fire is 150 rnds/min/gun. Elevation limits are +85/-10 degrees. Working circle radius is 1.757 m [69.2 in]. Total weight, without ammunition, is 600 kg [1320 lb]. Magazine capacity is 150 rnds.

There is also a modern twin enclosed 14.5-mm machine gun, in Zhuk-class patrol boats, which have been widely exported.

◆ DShK and DShKM

Caliber: 12.7-mm/76
Rate of Fire: 540-600 rnds/min (effective rate 80)
Muzzle Velocity: 860 m/sec
Maximum Range: 7000 m (1000-2000 m effective range)
Weight: 35.7 kg

This is a standard Soviet heavy machine gun, also used as a supplementary naval gun. It is gas-operated and has a flash suppressor. There are both single and twin mounts. DShKM differs from DShK only in having a simpler ammunition feed. Both guns are of prewar origin. In land service, they survive as standard tank antiaircraft guns, although newer tanks use the later NSVT. The basic gun has been very widely exported in Czech- and Chinese-built versions and may, therefore, be used by numerous Third World navies as a supplementary weapon. It is currently in production in China (PRC, as Type 54), North Korea, and Pakistan. It is definitely used by the Chinese and Iranian navies and is now being mounted on board some Soviet warships.

Typical performance includes penetration of 20 mm of armor at 500-m range, or 13.2 mm at 1000 m.

The NSVT is lighter, simpler, more reliable, and less expensive to manufacture. Its action is similar to that of the U.S. M73. It is also used in a tripod ground version (as the NSV). Presumably, then, it will ultimately displace DShKs and DShKMs used at sea. Cyclic rate is 680-800 rnds/min (effective rate 100 rnds/min), and maximum range is 8000 m (effective AA range is 1400 m in the AA role). Weight is 25 kg, including a tripod mount. In ground service, this gun normally uses a 50-rnd ammunition box. Development began in 1969, and the NSVT first appeared on T-72 tanks in the early 1970s.

UNITED KINGDOM

◆ 4.5-in Mk 5

Caliber: 4.5-in/45 (114 mm; 55-lb projectile)
Rate of Fire: 14 rnds/min (firing cycle 4.3 sec)
Muzzle Velocity: 2460 ft/sec **Maximum Range:** 20,750 yd
Training Rate: 20 deg/sec (elevation 20 deg/sec)
Elevation: +55 deg
Ammunition Capacity: none on mount
Weight: 33,562 lb **Working Circle:** 188-in radius

A Soviet under-and-over 12.7-mm machine gun on board the *Udaloy*-class destroyer *Admiral Vinogradov*, 1990. The ship carried 4 such mounts. (S. Zaloga)

This single open mount survives on board "Tribal"-class frigates in the Indonesian navy and on board the Malaysian *Rahmat*. No examples of the earlier British destroyers with single guns survive. The mounting itself was a converted 4.7-in CP XXII.

The rates of train and elevation listed above apply to the gun when it is under power control. The gun can also train and elevate under manual control, at slower rates.

◆ 4.5-in Mk 6

Caliber: 4.5-in/45 (55-lb projectile, 30–33-lb cartridge)

Rate of Fire: 10–12 rds/min/barrel (theoretical rate 24 rds/min/barrel)

Muzzle Velocity: 2460 ft/sec (derated to 2350 ft/sec in practice)

Maximum Range: 20,000 yd (maximum altitude 19,700 ft)

Training Rate: 25 deg/sec (elevation 25 deg/sec)

Elevation/Depression: +80/–15 deg

Ammunition Capacity: 80 shells, 45 cartridges in gun bay

Weight: 98,560 lb (revolving mass)

Working Circle: 218 in (radius)

(Below) A "Tribal"-class frigate displays her 4.5-in Mk 5 gun, forward. The director is MRS 3, carrying a Type 903 radar. This particular ship, HMS *Mohawk*, no longer exists, but 3 sisters survive in the Indonesian navy. (HMS Excellent)

This postwar, enclosed semiautomatic twin mount is found on many frigates and on ex-British "County"-class destroyers now transferred to other navies. At the end of 1988 only 2 of these mounts survived in Royal Navy service, on board the frigates *Achilles* and *Ariadne*. This weapon is roughly equivalent to abortive U.S. 5-in/54 semiautomatic twin mounts designed at the end of World War II, the rate of fire being somewhat slower. The very high rate of fire initially expected could not be realized in practice because the power rammer was unsuccessful; the guns had to be hand-loaded. A figure of 18 rds/min/gun was sometimes achieved.

Unlike previous types, this gun was designed from the outset for automatic aiming and for a high rate of fire. The weapon had many novel features, notably a loading tray, with which the gun recoils, and a rammer, which is pushed clear of the gun's axis by the vertically closing breechblock. Welding was

A twin 4.5-in mounting Mk 6, on display at Whale Island, 1985. (R. Cheung)

used extensively for the first time in British gun-mount construction. The training mass was entirely supported on a cantilevered structure that provided a circular gun bay clear of obstructions, for much easier transfer of ammunition to the revolving structure. This mounting was also unusual in using hydraulic rams for elevation. Ammunition was supplied by 2 magazines; the revolving structure had 1 cartridge hoist and 2 shell hoists per gun, so 2 types of ammunition could be used. The gunhouse plating is 0.375 in thick.

The only surviving examples of the earlier twin Mk 4 are 2 mounts on board the Iranian destroyer *Damavand* and 2 on board the Pakistani *Badr*, the sole surviving examples of the "Battle" class. This mounting weighed 46.3 tons, 11.2 tons of which were accounted for by a 0.5-in gunhouse. Elevation limits were +80/-5 deg.

Mk 7 would have been similar to Mk 6, for the *Malta*-class carriers and the *Lion*-class battleships, all of which were canceled at the end of World War II.

◆ 4.5-in Mk 8

Caliber: 4.5-in/55 (46-lb HE shell, complete round 80.5 lb)
Rate of Fire: 25 rnds/min **Muzzle Velocity:** 2850 ft/sec
Maximum Range: 24,000 yd
Training Rate: 40 deg/sec (elevation 40 deg/sec)
Elevation/Depression: +55/-10 deg
Ammunition Capacity: 16 rnds
Weight: 25.75 tons total (rotating mass 15.1 tons)
Working Circle: radius 19 ft 11 in

A 4.5-in Mk 8 on board HMS Glasgow, 1990. (Author)

This modern British unmanned single 4.5-in mount is installed on many current British frigates and destroyers. It is approximately equivalent to the U.S. 5-in/54 Mk 45, firing relatively slowly. The shield is fiberglass. Ready-service rounds are carried vertically, in an indexing feed ring, 2 spaces 180 deg apart normally being kept free for special types of ammunition, such as star shell. Mk 8 can open fire in 10 sec from the shut-down state. The developers considered rapid response more important than rapid rate of fire in self-defense against missiles, since each proximity-fuzed shell should be quite lethal, and since there would not, in any case, be much time for many rounds to hit. For the same reason, the gun is provided with a single multipurpose shell suitable for both air and surface action. Fuze mode is selected electronically just before the shell is rammed.

The gun itself was designed by the Royal Armament Research and Development Establishment (RARDE); modeled on the army's Abbot 105-mm howitzer, the gun has a muzzle brake and a fume extractor. The Royal Navy required that Mk 8 be able to sustain fire for 7.5 min (90 rnds). Water-cooling was rejected because it would have added too much weight, and the barrel had to be specially designed for sustained firing without cooling by water. Vickers designed the mounting.

The prototype Mk 8 was built in 1966, and the first installation was on board the Iranian frigate *Zaal* (now *Alborz*) in March 1971. HMS *Bristol* was the first British warship so fitted.

Vickers has developed a new HE/ER (high-effect/extended-range) ammunition, which employs base bleed and an improved shape to achieve 22% more range; in 1989 Vickers hoped ultimately to achieve over 30% more range, i.e., over 31,200 yd. In addition, standard muzzle momentum is achieved at a lower operating pressure, for reduced gun wear.

Shell types are high effect (HE), illuminating, radar echo (chaff for I- or J-band, either as a decoy or for wind-finding), AA practice (with a small flash filling to show that the fuze has functioned), and surface practice (completely inert). The 2 fuze types are N7 (mechanical time) and N97 (multirole: direct action, proximity low- or high-altitude, and post-impact delay). Rated barrel life is 3300 rnds.

◆ 4-in Mk 19

Caliber: 4-in/45 **Rate of Fire:** 12 rnds/min/gun (firing cycle 5 sec)
Muzzle Velocity: 2660 ft/sec **Maximum Range:** 19,850 yd
Training Rate: 20 deg/sec (elevation 20 deg/sec)
Elevation/Depression: +80/-10 deg
Ammunition Capacity: none on mount
Weight: 17.8 tons **Working Circle:** 141-in radius

One twin mount survives on board the Malaysian frigate *Hang Tuah*, and 2 similar guns arm the Egyptian sloop *Tariq*.

Twin 4-inch gun. (Public Archives of Canada)

(Above) The Chilean destroyer *Almirante Riveros* shows the special Vickers 4-in guns manufactured for her. The radar at her masthead is SNW-12, with an SNW-20 slotted waveguide below it. She was later fitted with a Plessey AWS-1 aft but still retains the 2 SNW-20 antenna forward. (Vickers)

Mk 19 was once an extremely common weapon. The 2 guns share a common cradle, but each fires separately, with a separate recoil system.

◆ Vickers 4-in

Caliber: 4-in/62 (32-lb projectile)
Rate of Fire: 50 rnds/min (service rate probably about 40)
Muzzle Velocity: 2953 ft/sec
Maximum Range: 18.5 km (maximum altitude about 12,000 m)
Elevation/Depression: +85/-7 deg
Ammunition Capacity: 56 rnds (two 28-rnd hoppers)
Weight: 47,040 lb

As originally conceived, this mount would have carried the same gun as the standard Mk 19, in a mounting similar to that of an abortive 5-in automatic gun designed by Vickers. The original weapon, developed from the army's new mobile 4-in high-velocity antiaircraft gun, was proposed about 1953 for the projected (abortive) rearmament of the Argentine training cruiser *La Argentina*, and also for Peruvian and Chilean ships. Other potential buyers at this time were Israel and Venezuela, to use the gun either as the main battery of a 1200-ton escort or 2000-ton fast escort, or as the secondary battery of a 2600-ton destroyer also armed with 4.7-in antiship guns.

The unusual feature of the mounting is that it loads through the trunnions, the shells being carried in two 28-rnd hoppers between the trunnions. The hoppers could be topped up to maintain a rate of about 30-40 rnds/min (Vickers claimed 50 rnds/min, but the DNO [Director of Naval Ordnance] of the day was skeptical). Weight, with the standard 45-caliber 4-in barrel, was 19 tons empty (plus 1.6 tons of ammunition), and elevating limits were +85/-7 deg.

These guns arm the 2 *Almirante Rivero*-class Chilean destroyers and were being rehabilitated in Chile in 1987-88.

There was also a proposed 105-mm version, for the Argentine navy; that version would have weighed 53,760 lb and was rated at 40-46 rnds/min.

◆ 3-in Mk 6

Caliber: 3-in/70
Rate of Fire: 95-113 rnds/min/gun (designed for 120 rnds/min/gun) (15-lb shell) **Muzzle Velocity:** 3400 ft/sec
Maximum Range: 19,500 yd
Training Rate: 60 deg/sec (elevation 30 deg/sec)
Elevation/Depression: +90/-15 deg
Ammunition Capacity: 161 rnds/gun (2 hoppers per gun, 100 and 38 rnds, with others in the system); total 2000 rnds in the magazine
Weight: 83,150 lb (revolving mass, including 34 rnds/gun)
Working Circle: radius 234 in

This mount was designed in Britain but survives only on board 7 active Canadian frigates. Mk 6 used the same ammu-

A twin 3-in/70 Mk 6 on board the Canadian destroyer *Gatineau*, 1988. (S. Terzibaschitsch)

nition and the same gun tube as the U.S. twin 3-in/70 but was less ambitious in concept and, perhaps as a result, was much more successful. In the Royal Navy, Mk 6 was the intended main battery of the postwar frigates, but it was not ready in time, and the twin 4.5-in Mk 6 was substituted.

The guns are water-cooled. There are 2 hoists on the nonrotating structure (25 rnds/min), and the hoists top up the hoppers that rotate with the guns.

◆ 40-mm Mounts

Caliber: 40-mm/56.3 (1.97-lb shell)
Rate of Fire: 120 rnds/min (140-150 with gun horizontal)
Muzzle Velocity: 2890 ft/sec
Maximum Range: 10,750 yd (but shells generally self-destruct at 3000-3500 yd)
Training Rate: 35 deg/sec (elevation 28 deg/sec; 35 deg/sec in Canadian-built mountings)
Elevation/Depression: +90/-15 deg (Mk 5)
Ammunition Capacity: 12 clips on mount (48 rnds); Mk 9 has 6 clips on the mount (plus the clips in the gun).
Weight: 6.397 tons

Data above apply to the Mk 5 twin power mount.

The Royal Navy still uses a few 40-mm Mk 7 and Mk 9 mounts, carrying the standard World War II 40-mm L60 gun (see the Swedish Bofors 40-mm/60 above for details). The Royal Navy expected to adopt the postwar 40-mm/70 but bought Sea Cat missiles instead; the British army did buy the L70 gun.

Mk 5 was the standard twin mount (water-cooled guns) with remote power control. There was also a Mk 6 sextuple mount, now extinct, the only British naval Bofors that did not use the standard gravity-feed clip. Instead, each gun had a 36-rnd ammunition tray operated by gun recoil.

Mk 7 is an adapted army single air-cooled mounting, with a light alloy structure and a splinter shield. Using 1-operator laying and a gyro sight, with a separate loader, Mk 7 is hydraulically driven, with the motor and pump on the revolving structure. Elevation rate is reported as 45 deg/sec, and total weight is about 3 tons. Mk 8 was an unsuccessful interim design with

Standard British single 40-mm gun, probably Mk 7. The rack is for spare clips. (National Maritime Museum)

Single 40-mm mount Mk 9, on board a British minesweeper. (A. Raven)

battery power. Mk 9 is a refurbished Mk 7 with electric rather than hydraulic drive. Mk 9 was used in the Falklands.

The Australian Maribymong Ordnance Factory remanufactures existing Mk 3 and Mk 7 mounts, designated 40/60 AN. The 40/60 AN first went to sea on a *Freemantle*-class patrol boat in 1980; as of early 1989, 30 were in service. This mounting has also been adopted by the Thai navy. Time between refits is 6 yr, compared to 9–11 months for Mk 7. Total weight without ammunition is 1500 kg [3350 lb]. Elevation limits are +90/–5 deg. Training rate is 40 deg/sec; elevation rate is 20 deg/sec; creep rates in both dimensions are greater than 20 deg/min. The system can be stabilized as a customer option, but none has yet been stabilized. Existing mountings are converted by discarding old components, which are difficult to maintain, and by replacing them with modern power, hydraulic, and control systems. The hand-drive train is replaced by a low-pressure oil-hydraulic system with an integrated power pack, controlled by a T-handle for rapid target acquisition coupled with slow and smooth tracking. The hydraulic power pack is fully enclosed for greater protection. The electrical box is relocated below decks.

The British version of the Bofors gun could accommodate two 4-rnd clips (or 10 rnds, with 2 loose between the clips), and it was claimed that a single loader could work fast enough for the gun to fire a burst of 24 rnds.

Another wartime British 40-mm mount, the Boffin, is to arm the new Canadian mine-countermeasures craft. The weapons

had been mounted on board the Canadian aircraft carrier *Bonaventure*, and then to protect Canadian airfields in Germany when the carrier was discarded. Boffin, a twin 20-mm Mk V or VC power mounting adapted to take a single air-cooled 40-mm gun, was very widely used late in World War II. The Canadian Boffins used for airfield defense were powered by on-mount gasoline engines. In August 1990 Mk 5C (Boffin) mounts earmarked for the mine-defense ships were diverted to the 3 Canadian ships going to the Persian Gulf: 2 each for the destroyers *Athabaskan* and *Terra Nova* and the replenishment ship *Protecteur*. They were supplemented by six 0.50-cal machine guns on board each ship.

◆ 30-mm A32

Caliber: 30-mm/75 (Type 831L cannon) (0.36-kg shell; 1.0-kg complete round) [0.8/2.2 lb]

Rate of Fire: 600 rnds/min/gun **Muzzle Velocity:** 3540 ft/sec

Effective Range: 3300 yd (maximum 11,100 yd)

Training Rate: 90 deg/sec (elevation 60 deg/sec)

Elevation/Depression: +80/–15 deg

Ammunition Capacity: A version: 160; B version 320

Weight: 3740 lb without ammo or gunner; ammo weight is 352 lb (A) or 704 lb (B) **Working Circle:** 8.25 ft [2.57 m]

This BMARC mount, for twin Hispano-Suiza guns, predated the twin Oerlikon that the company later marketed (BMARC was a Hispano-Suiza subsidiary, and Oerlikon later took over Hispano-Suiza). A32 is similar in overall configuration and was presumably adapted to the Oerlikon gun. The mount was designed in 1967, and 2 prototypes were produced for Finland (delivered 1968: one Series A, one Series B).

In the A version, the ready-service ammunition boxes elevate with the mount. In the B version they do not.

◆ 30-mm (Type GCM-A01)

Caliber: 30-mm/75 **Rate of Fire:** 1300 rnds/min

Muzzle Velocity: 1080 m/sec [3540 ft/sec]

Maximum Range: 10,000 m [33,000 yd]

Training Rate: 75 deg/sec (elevation 50 deg/sec)

Elevation/Depression: +80/–15 deg

Ammunition Capacity: 160 rnds/gun (A03-1: 160 or 250 rnds/gun; A03-2: 250 rnds/gun; A03-3: 320 rnds/gun)

Weight: 2000 kg (A02); A03-1: 2150 kg; A03-2: 2050 kg; A03-3: 1900 kg [4410/4740/4520/4190 lb]

Working Circle: 2520 mm [99.2 in]

For this BMARC/Oerlikon project, Oerlikon provided the twin 30-mm guns and their new APDS ammunition, announced in 1975. The mount is gyro-stabilized and power-driven, with either local or remote control. The guns are twin 30-mm Type KCB cannon. BMARC (British Manufacture and Research Co.)

30-mm GCM-A01 twin mount. (A. Raven)

was part of the Oerlikon-Bührle Group, hence the use of Oerlikon guns as part of the weapon.

The original A01 version was introduced in 1968. A02 entered British naval service as an emergency close-in defense gun during the Falklands War, the Royal Navy buying 8 of the GCM-A02 version. The current version is A03. The version in the Brunei fast patrol craft built by Vosper Singapore in 1978 is GCM-B01, controlled by a Sperry Sea Archer 1.

BMARC also marketed the twin 35-mm Oerlikon gun (Type GDM-A; see the Swiss guns above).

◆ Laurence Scott LS-30B (DS 30)

Caliber: 30-mm **Rate of Fire:** 650 rnds/min
Muzzle Velocity: 1080 m/sec [3540 ft/sec]
Training Rate: 55 deg/sec (elevation 55 deg/sec)
Elevation/Depression: +65/-20 deg
Ammunition Capacity: 160 rnds
Weight: 1.2 tons (with ammunition)

LS-30B is a stabilized single mounting that carries the Oerlikon 30-mm KCB cannon. Twenty-five were ordered in September 1984 to arm "Duke"-class frigates and to replace some existing Bofors 40-mm/60 guns in Mk 7 and Mk 9 mounts, and the gun entered service in 1987. The mount was conceived as a gun adaptation of an existing optical director. Power-operated and gyro-stabilized, the gun is controlled by joystick. The original version, LS-30R, carried a 30-mm Rarden gun (as used on land) with a 21-rnd magazine. An alternative version, carrying a Mauser cannon, was designated LS-30F.

DS-30B, shown on board HMS *Brecon* (July 1989) and at the RNEE in 1989. (U.S. Naval Institute and Author)

There were 3 versions of the basic mounting: Mk I, controlled locally by an operator with a joystick; Mk II, controlled remotely by the director; and Mk III, with an added digital predictor. The Rarden Mk I version was tested on board HMS *Londonderry* in 1981. Overall system dispersion was less than 3 mrad in sea-state 5, and in one trial a towed 2-m² target was hit 80% of the time at 1000-1300 m in poor visibility. This mount weighed 800 kg including gun, with a 2.2-m working circle (radius), and training/elevation velocities of 30/35 deg/sec; elevation limits were +70/-20 deg. The gun could fire a 6-rnd burst, or 21 rnds if an extra magazine was fitted.

This mount was redesignated DS 30 in 1986, the manufacturer having been renamed Defense Equipment and Systems, Ltd. The company offers versions of the basic mount armed with a variety of guns: DS 30B (30-mm Oerlikon KCB cannon), DS 30E (30-mm EBO-Mauser cannon), DS 30F (Mauser 173 Model F), and DS 30R (30-mm Rarden cannon). There is also a DS 25M carrying the U.S. M242 Bushmaster 25-mm cannon, a weapon also used by the U.S. Navy. As of 1987, DS 30E was being evaluated by the Greek navy, and a NATO coast guard was evaluating the DS 25M. The Royal Navy uses DS 30B. Sea trials, on board the minesweeper *Cottesmore*, were completed at the end of October 1986.

This weapon is designated Single 30-mm Gun Mounting Mk 1 in British service; the first ship fitted with it is HMS *Cornwall*.

◆ L7A2

Caliber: 7.62-mm **Muzzle Velocity:** 838 m/sec
Maximum Rate of Fire: 625-750 rnds/min
Maximum Elevation/Depression: +45/-10 deg
Ammunition Load: 200 rnds **Maximum Range:** 1800 m
Weight: 10.9 kg (gun alone, empty)

L7A2 is the standard British light machine gun, and its role in the Royal Navy is broadly analogous to that of the U.S. 0.50. L7A2 serves as a policing weapon on board "Ton"-class minecraft, and the "Isles"- and "Castle"-class offshore-patrol vessels. It was also pintle-mounted on board larger ships, e.g., for close-in defense. The gun, which is a standard air-cooled infantry machine gun, can be mounted on a pedestal, a buffered tripod, or a bulwark pintle.

This gun is based on the Belgian FN MAG.

◆ GBN 155

Caliber: 155-mm/52 **Maximum Rate of Fire:** 12 rnds/min
Maximum Range: 24,000 m [26,200 yd]
Weight: 13,550 kg [29,860 lb]

This modified 155-mm/52 gun-howitzer (GBT) was exhibited by VSEL (and later by the Royal Ordnance Factories [ROF] at the RNEE 1983 and later shows, as a future naval gunfire support weapon that would use ammunition widely available for ground forces. This project lost much of its rationale when the Mk 8 4.5-in gun was incorporated in the Type 23 frigate. However, in 1988 ROF was considering a joint venture with the U.S. company FMC to market 155-mm naval guns, perhaps using FMC's vertical loader.

◆ VSEL 155-mm Naval Gun

Caliber: 155-mm/52 **Rate of Fire:** 10 rnds/min
Maximum Range: 40 km (with base-bleed projectiles)
Elevation/Depression: +80/-15 deg
Weight: about 20 tons plus 3.5-ton hoist

VSEL announced its new private-venture medium-caliber gun, a collaborative effort with Royal Ordnance, at RNEE 1989. Like several other lightweight gun designs, this one avoids allowance for antiaircraft fire to avoid complexity; the very high maximum elevation is valued for shore bombardment. VSEL claimed some Royal Navy interest, presumably generated by Falklands experience. The caliber was chosen because the gun was already used by the British and other NATO armies, with a wide range of specialized shells (VSEL did not, however, study the HERO consequences of using army shells, a problem that

helped kill the U.S. 155-mm naval gun). VSEL proposals include the use of the same projectile with the same charge, but with alternatives for greater lethality, accuracy, and range. The 2 main options are to place the charge in a metal case (which is removed after firing) for automated ramming, the charge and projectile being rammed together, or alternatively to use a stub case (standard round—fixed round). VSEL would prefer to use the version already in service on land, in which the charge burns completely, leaving a metal case to eject. The case encloses the bagged charge to simplify ramming; it is not a cartridge case in the usual sense. It, therefore, need not be solid.

The crew would be 2 in the gun bay, and 3 or 4 in the magazine, with a capacity of 200–250 rnds. The rounds and their charges are too massive for convenient automatic drum loading. This is not the GBN 155 described above.

◆ 105-mm Autonomous Patrol Gun

Caliber: 105-mm/51 **Muzzle Velocity:** 2400 ft/sec (HE)
Rate of Fire: 12–14 rnds/min (hand-loaded)
Training Rate: 30 deg/sec (elevation 10 deg/sec)
Maximum Range: 6000 m [6600 yd]
Elevation/Depression: +45/–12.5 deg
Ammunition Load: 30 rnds
Working Circle: swept radius 14 ft 9 in **Weight:** 6 tons

This adapted L7 tank gun, developed by the Royal Ordnance Factories, was first displayed in 1980. The 105-mm could be fitted in patrol boats from 35-m length up. Cost was estimated at £600,000 in 1981. The muzzle velocity given above is for high-explosive (full-caliber) shells; with discarding sabot shells the tank gun attains about 4800 ft/sec. Presumably, naval operators would not use such shells. Although sales were not forthcoming, the weapon is interesting as a Western equivalent of the standard Soviet practice for river patrol boats. No current Western river-gunboat weapon of this type is in service, although the U.S. Navy did use tank-type howitzers in Vietnam, on board monitors.

◆ Sea Venom

Radamec Sea Venom, a pair of remote-controlled 0.50-cal machine guns on the company's stabilized 429 servo platform. (Radamec)

This Radamec remote-controlled machine-gun mount was announced at RNEE 1989. It is a Type 429 servo-controlled platform carrying two 0.50-caliber machine guns, with 200 rnds each; the platform can carry heavier weapons if necessary, or 57-mm parachute flare launchers. It can be controlled by a Series 1000 stabilized director. Nominal height is 1 m (carrying the two 0.50-caliber guns), swept radius is 1.2 m, and weight is about 300 kg, including 400 rnds. Elevation limits: +50/–30 deg. Sea Venom can train and elevate fast enough to engage surface craft and helicopters from a small, lively, fast attack boat, but not quickly enough to engage fast aircraft.

UNITED STATES

◆ 16-in/50

Caliber: 16-in/50 (2700-lb AP shell, 1900-lb HC shell)
Muzzle Velocity: 2425 ft/sec AP; 2690 ft/sec HC
Rate of Fire: 2 rnds/min/gun
Training Rate: 4 deg/sec (elevation 12 deg/sec)
Maximum Range: 40,185 yd AP; 41,622 yd HC
Elevation/Depression: +45/0 deg (depression 2 deg in turrets I, III)
Working Circle: 36 ft 4.5 in
Weight: 1701–1708 tons (per turret) without ammunition

16-in/50 salvo. (Edward J. Bonner)

The 16-in/50s are now the most powerful naval guns in the world, the sole active survivors of the battleship era. The guns are mounted separately and elevate separately. Each gun loads at a fixed 5-deg elevation. After firing, each gun depresses to its loading elevation and then elevates again to fire. Each turret has a crew of 77, plus 30–36 total in the 6 magazines. The AP round will penetrate 30 ft of concrete. In Vietnam single HC rounds were used to clear 200-yd-diameter landing zones in triple-canopy jungle; the rounds made craters 50 ft wide and over 20 ft deep. The most important technical innovation of the Vietnam period was "Swedish additive," which was wrapped around the charge and which, when burned, reduced barrel wear. During Vietnam, too, some work was done on extending the gun's range. In the spring or summer of 1967 there was a proposal that sabot 280-mm shells (left over from the army's "atomic cannon" program, but nonnuclear) be fired, to ranges as great as 100,000 yd. The Naval Ordnance Station, Indian Head, proposed a \$4-million, 18-month program to modify 23,000 such projectiles. There was, however, concern that stable flight could not be assured, and that fuzes could not survive the heat of very high velocity flight. However, exploratory shots were fired at Yuma (up to 60,000 yd) and in Barbados (in the latter case, from 2 surplus 16-in/45 tubes welded end to end). In February 1969 the Barbados gun fired an 835-lb shell at 40 deg of elevation (4230 ft/sec) to 74,650 yd; in November 1968 the gun fired a 745-lb shell (4550 ft/sec) to 83,850 yd. It was estimated that at 45 deg of elevation the light shell would reach 102,000 yd (93,000 yd at 40 deg). The program died, presumably when the *New Jersey* was deactivated. However, these ranges are about what would be needed by a ship well offshore (i.e., over the horizon) to reach a V-22 landing zone inland.

As of 1981, when the battleships were being reactivated, the reported stock of ammunition was: 15,500 HC (high-capacity) shells, 3200 AP shells, and 2300 BL&P (blind-loaded training) shells. A total of 12,500 full-service and 12,600 reduced charges

were on hand. As a measure of consumption, USS *New Jersey* fired 771 rounds during World War II, 6671 during the Korean War and her midshipman cruises, and 5688 during the Vietnam War. As of 1986, it was expected that new 16-in shells would have to be manufactured for delivery in 1990; the last new 16-in shells had been made during the Korean War.

There are now 4 special-purpose shells using the 16-in HC (1900-lb) body but containing submunitions. Mk 143 HE uses an army proximity fuze. Mk 144 carries 400 M43A1 wedge (anti-personnel) grenades and is time-fuzed. Mk 145 is a time-fuzed high explosive. Mk 146 uses the time fuze and carries 666 shaped charge (SADARM) bomblets (M42/M46/M77 dual-purpose anti-personnel/antimatériel).

An operational requirement for improving the 16-in guns was approved in May 1986. It includes the development of a new 13-in subcaliber cargo shell carrying about 600 dual-purpose anti-personnel/antimatériel submunitions (SADARM) to a considerably greater range than the 16-in shell can achieve. Although the 13-in shell is much lighter and is of smaller diameter, it has a cavity about as large as that of the full-caliber shell. Other army submunitions are being evaluated. The design of the 16-in sabot and the 13-in body were begun in FY86; tests were expected in FY90, and the lead ship was to have received the first shells that year, with approval for full production expected in FY92. The shell acts as a bus and can carry other loads: possibilities include chaff, smoke, and land mines (which are already carried by shells on shore).

The sabot shell was chosen for extended range because it was simpler than a proposed rocket-boosted projectile. There have been recurring proposals for a ramjet shell, a gun-launched missile, but they have been put aside because of their inherent complexity.

The other major element of the program is the integration of a digital gun computer, a Mk 160 similar to that of the *Arleigh Burke*, into the Mk 38 FCS. The digital computer can make allowances for the different ballistics of the new shells, and in future it may be connected to a shell-tracking radar that will measure the actual muzzle velocity of the guns on a round-by-round basis, so that ballistic corrections can be applied. Neither improvement would have been possible with the old analog computer, in which ballistic formulas are represented by the complex shapes of cams.

When the guns were brought back into service, there were initial problems with powder, i.e., with the consistency of fire on a round-to-round basis. The problem is reflected in variations in muzzle velocity. Powder of the World War II era was expected to produce a variation of no more than ± 10 ft/sec; service figures were ± 5 ft/sec. During the Korean War typical figures were ± 14 ft/sec, and during operations off Lebanon this deteriorated to ± 32 ft/sec. The reworking program restores the powder to the original standard of ± 10 ft/sec.

Existing powder supplies were rebled during 1986, to improve the gun's accuracy. At that time the navy held large stocks of bulk 16-in/45 powder, plus prebagged 16-in/50 bags. The choices were either to remix and reload the 16-in/50 bags (but matching lots was difficult because the bags had differing histories) or to bag the bulk-stored 16-in/45 powder. Since the bulk-stored powder had more uniform characteristics, it was used. There is a small difference in composition between 16-in/45 and 16-in/50 powder, but it was possible to bag the former to 16-in/50 specifications and to impose sufficient quality control to come within the original specification for muzzle velocity noted above. New powder production will not be needed for some time: as of 1985 the navy had about 12 million pounds of 16-in/45 powder on hand. This material does not deteriorate, but it does age, partly because its volatile components vanish in the first few years. Afterward, change is more gradual.

As modernized, each turret carries a DR-810 radar that measures the muzzle velocity of each gun. These data make it easier to predict the velocity of the next shot (since it reflects the state of wear of the gun tube on the last shot). The radar elevates to follow gun elevation, and gun velocity is displayed

in the turret and printed out in each plotting room. The radar occupies a small radome directly on the roof of each turret, over the center gun; the radar aft is on a short tripod. There are also 2 HP-85 digital computers. Computer IBC 1 calculates expected initial velocity based on measured gun erosion, powder temperature, and history of initial velocities; the output is compared with radar velocity data. Computer IBC 2 corrects for trunnion height, target height, earth curvature and rotation, ballistic density, and air temperature, calculating fuze time setting for projectiles (Mks 144, 145, and 146) that require it.

The combination of better powder and this degree of detailed calculation makes for considerable accuracy at very long range. For example, firing off Crete on 23 November 1987, the *Iowa* fired fifteen 2700-lb AP rounds (5 from the right gun of each turret) at a range of 34,000 yd. The pattern size was 219 yd (0.64% of total range), and 14 of the 15 shells were within 250 yd of the center of the pattern; 8 of the 15 were within 150 yd. Shell-to-shell dispersion was 123 yd (0.36% of range).

Considerable effort has been expended to reduce wear on the barrels. The 16-in/50 gun was designed to fire 290 full-charge AP rnds before tube replacement (the lighter HE shell is equivalent to only a fraction of the full AP rnd). During the Vietnam War the battleship *New Jersey* used a titanium-dioxide jacket that reduced the wear per full-service round to the equivalent of 0.26 such rounds. A newer wax and polyurethane jacket does significantly better. One jacket is used around each bag of the propelling charge; the jacket forms a gaseous layer that protects the gun's bore. These jackets have been so successful that mechanical fatigue, rather than erosion, is now considered the limiting factor in liner lifetime; the 16-in/50 Mk 7 gun is now rated at 1500 FER (fatigue equivalent rounds). Even so, there was some concern at the beginning of the program that insufficient barrel liners remained. However, as of 1986 there were 35 new barrels on hand (one with a used liner), and also at least 10 new liners.

A 16-in Gun Improvement Conference was held in mid-June 1987. It called for several improvements:

- NSWC Dahlgren was tasked to produce super-charge powder to increase velocity and range of 1900-lb shell (full capacity of barrel not yet utilized).
- an increase in angle of fall of shot; an incremented charge would give more flexibility in angle of attack. Dahlgren was to develop a special powder load to enable reverse slope firing at shorter ranges.
- powder used in tests is often at 90°F; ships store it at 70°F and, thus, get longer ranges than predicted. Dahlgren was to evaluate powder charges at 70°F to measure range variation.
- a floating target was needed for surface target practice.
- the Mk 48 computer (WW II technology) had to be replaced by a modern digital plotting table.

Longer-term proposals were:

- full-charge flashless powder for 16-in/50 for night action.
- a new fire-control radar, to replace the existing Mk 13, a unique emitter that identified its platform as a battleship. Proposals included the use of a laser range-finder/illuminator. This proposal probably explains the installation of an SPQ-9A radar on board the battleship *Iowa*, which functioned as test ship for new installations.
- the Mk 37 GFCS should be replaced because it is obsolete.

In April 1989 the *Iowa* suffered an explosion in the center gun of her No. 2 turret before firing. Her turret was not immediately repaired, and she operated for a time with only 6 guns. In January 1990 it was announced that she and the *New Jersey*, which had been in commission the longest, would be returned to reserve; later it was decided not to repair the *Iowa*'s No. 2 turret. The other 2 ships are to remain in active service, and presumably the 16-in improvement program is to continue. As of mid-1990, the marines were pressing for the longer-range

saboted projectiles, which they considered essential to support their new doctrine of deeper-penetration landing.

◆ 8-in/55 Rapid-Fire

Caliber: 8-in/55 **Muzzle Velocity:** 2700 ft/sec HC; 2500 ft/sec AP
Rate of Fire: 10 rnds/min/gun
Training Rate: 5 deg/sec (elevation 8.2 deg/sec)
Maximum Range: 31,350 yd HC; 30,100 yd AP
Elevation/Depression: +41/-5 deg
Working Circle: 23 ft 3.0 in **Weight:** 451 tons

Triple 8-in/55 automatic turrets on board 1 of the 2 surviving *Des Moines*-class cruisers. The ship on the right is the *Newport News*, which has been stricken. Although these ships have been out of service for over a quarter-century, they are in excellent condition. The smaller guns are twin 5-in/38s and twin 3-in/50s; the latter would presumably be landed if the ships were recommissioned.

These guns, the sole survivors of a type that once armed many U.S. cruisers, remain in reserve on board the *Des Moines* and *Salem*. The guns are mounted in triple turrets. Work began in May 1943, after the development of a twin automatic 6-in/47 had shown that a large gun could be made to fire rapidly, i.e., about 10 rnds/min. This high rate of fire was achieved by all-angle loading with semifixed (i.e., cased) ammunition, all ammunition being power-handled. The mount was considered quite successful in service, suffering only 1 bad accident (which, however, knocked out the No. 2 turret of the cruiser *Newport News*).

◆ 6-in/47

Caliber: 6-in/47 (105-lb HC shell, 130-lb AP)
Muzzle Velocity: 2800 ft/sec HC; 2500 ft/sec AP
Rate of Fire: 10 rnds/min/gun (rating: 3 rnds/min/gun)
Training Rate: 10 deg/sec (elevation 11 deg/sec)
Maximum Range: 24,010 yd
Elevation/Depression: +60/-5 deg (load at angles up to 20 deg)
Working Circle: 21 ft 7.5 in
Weight: 154-167 tons (for different turrets in the ship)

Only 1 ship still carries these triple mounts, the Chilean cruiser *O'Higgins* (ex-USS *Brooklyn*). The guns are semiautomatic, and they elevate together. The ammunition is semifixed. The gun's lifetime is about 750-1050 rnds at full charge. The associated director is Mk 34, similar to the battleship Mk 38. The crew per turret is 3 officers and 52 enlisted, compared with 17 enlisted for the semiautomatic Mk 39 5-in/54, and with 6 enlisted for the abortive automatic 8-in/55.

◆ 5-in/54 Mk 42 and Mk 39

Caliber: 5-in/54 (70-lb shell) **Rate of Fire:** 40 (derated to 28)
Muzzle Velocity: 2650 ft/sec
Maximum Range: 25,900 yd (Time of flight to 10,000 yd at 6-deg elevation is 15.8 sec.)
Training Rate: 40 deg/sec (elevation 25 deg/sec)
Elevation/Depression: +85/-7.5 deg
Ammunition Capacity: 40 (automatically loaded)
Weight: 145,930 lb (Mod 0) **Working Circle:** radius 269 in

5-in/54 Mk 42 mount, USS *William S. Sims*, 1986. (L. van Ginderen)

Data are for Mk 42.

Mk 42 was the standard U.S. single 5-in gun mount of the postwar era, conceived as an automatic equivalent of the twin 5-in/38 with the same rate of fire (but firing a more powerful round). Later versions required fewer crew: 13 in Mod 9, compared with about 20 in earlier types. For example, remaining mounts use a single joystick control, whereas the original mount had separate pointer and trainer.

In all variants, the gun is fed by 2 parallel 2-stage hoists, each extracting ammunition from a loader drum. Shells and cartridge cases are loaded separately into the drums, each of which holds 20 complete rnds. Shell and cartridge case are transferred together from drum to lower hoist, then to an upper hoist, and then to a transfer tray (on a cradle) that swings up parallel to the breech; the left and right hoists operate alternately, so that 1 places a round in the right cradle while the other descends to pick up another. Each transfer tray contains a fuze setter; it drops into position between rammer and breech to load the round. Having loaded, the tray pops up to avoid the gun's recoil, and an empty case tray moves into position to receive the ejected case. The entire process is complex mechanically, and the Mk 42 acquired a reputation for jamming during protracted firing, e.g., on the gun line off Vietnam: hence the current derating to about half the originally projected rate of fire. Mk 42 Mod 10 has a special trouble-shooting status board.

A laser-guided 5-in shell, Deadeye, was developed by Martin Marietta, primarily for shore bombardment. Initially Deadeye was to have been guided by a shipboard laser designator incorporated in the Seafire (EX-121) director; but when Seafire was canceled, shell development continued, the designator being a marine mobile unit, MULE. Deadeye could also respond to a helicopter-borne designator. The shell was rocket-boosted for additional range. Deadeye was tested at sea on board the *Briscoe* in 1981, and the first 300 rnds were scheduled for delivery in FY89, with another 15,100 planned. Delays between 1981 and 1989 were largely caused by disagreements about the cost per round, and the program died in the FY89 round of budget cuts.

The guided shell was 60.97 in long, with pop-out fins at its nose (for guidance) and at its base (for stability), and Deadeye weighed 104.7 lb. The standard 5-in/54 rnd, including its cartridge case, is 60.93 in long; the shell itself weighs 57.3 lb (carrying 7.9 lb of high explosive). The shell could be either a shaped charge or fragmentation warhead. Given the great length, the guided shell had to be double-rammed: once for the shell and once for the separate cartridge case. That requirement roughly halved the rate of fire, and the need to accommodate markedly longer shells accounts for the FMC proposals for vertically loaded guns, described below. The estimated range of the rocket shells is 40,000 yd, compared with 20,000 yd for a conventional shell. With the demise of Deadeye, vertical loading is a much less urgent issue.

There was also an IR-guided shell, developed nearly concur-

rently with Deadeye, which would have been used as a secondary antiaircraft round. This shell did not enter production, although there is an IR fuze. The rationale was that there were numerous existing antiaircraft weapons, and that, with a warhead much smaller than that of Sea Sparrow, the shell would not have been worthwhile.

Finally, there is a rocket-boosted 5-in/54 shell, Mk 58 (the standard shell is Mk 65), weighing 58 lb and carrying 3.8 lb of explosive. With cartridge case, the full round is 61.25 in long. The solid-fuel motor burns for 34 sec, and the maximum range against a surface target is 31,090 yd, compared with 23,690 yd for the conventional shell.

In 1988 a 5-in cargo projectile was under development, to carry chaff and other loads (presumably submunitions).

The current program for ammunition development includes a super charge that increases range for the high-fragmentation 5-in shell and that also gives 2–4 times the barrel life of the existing charge (the super charge is also under development for the 3-in gun). This new LOVA (low-vulnerability ammunition) charge will also reduce a ship's vulnerability to fire and blast because rounds in a magazine will be less likely to cook off. A multifunction fuze (remotely set point-detonation, time, or multiproximity) is being developed, so that a single fuze can serve for all air and surface targets. The existing IR fuze is being improved to deal with cooler targets and to reject background clutter more effectively.

Mk 39 is a semiautomatic single 5-in/54 mount that survives on board 3 former Japanese destroyers, now reclassified as auxiliaries (*Akizuki* class). These weapons were removed from the U.S. aircraft carriers *Midway* and *Franklin D. Roosevelt*. The gun is the same as that in the Mk 42 mount, but the rate of fire is about 15 rnds/min because of manual loading. The mount weighs 87,500 lb. The shield is 0.75 in thick. Elevation limits are +85/–10 deg, and the mount trains at 30 deg/sec (elevation rate 15 deg/sec). The working circle's radius is 276 in.

The 5-in/54 Mk 42 has been manufactured under license in Japan (by the Japan Steel Works) since 1965.

◆ 5-in/54 Mk 45

Caliber: 5-in/54 (70-lb shell)

Rate of Fire: approx 20 rnds/min (17 measured in test)

Muzzle Velocity: 2650 ft/sec **Maximum Range:** 25,900 yd

Training Rate: 30 deg/sec (elevation 20 deg/sec)

Elevation/Depression: +65/–15 deg

Ammunition Capacity (on-mount): 20 (10 guided rnds)

Weight: 47,820 lb (no lower hoist)

Working Circle: radius 261 in

Mk 45 is the slower-firing, low-manning replacement for Mk 42. Mk 45 was intended as the simplest of a family of such

weapons, some of which would have fired as rapidly as Mk 42, and some of which might have had twin barrels, but only Mk 45 ever entered service. Mk 45 is remotely controlled; personnel requirements are 1 gun captain, 1 panel operator, and 4 ammunition loaders, all below decks.

Compared with Mk 42, Mk 45 has a greatly simplified mechanism. There is only a single loader drum, and it includes the fuze setter. Some guns have no separate lower hoist; when a lower hoist is present, it feeds the drum. Rounds are loaded into a single cradle, which swings from the vertical up into position behind the vertical breechblock, which rises to open. The round is rammed, and the block drops to close. The empty case is ejected when the gun counterrecoils, the empty case tray being mounted atop the slide. Misfired rounds are removed automatically, compared to manual procedures for Mk 42 and for the earlier 5-in/38.

The barrel's lifetime is 7000 rnds, compared with 3070 for the earlier gun tube of the Mk 42. About 1974 Mk 42's barrel life was rated at 2000 rnds.

Mod 1 allows the operator to change the type of ammunition remotely, whereas in Mod 0 such a change requires special procedures. Mod 1 also incorporates an electronic fuze-setter in addition to the earlier mechanical unit. The loading station is lowered to make room for the longer guided shells. In 1982, when Mod 1 was first tested, 6 different projectiles were planned: high capacity (HC), white phosphorus (WP), star shell (SS), illumination 2 (SS2), semiactive laser (SALGP, Deadeye), and IR guided (IRGP). The last 2 were later canceled. There were also 7 fuzes: mechanical time (MT), controlled variable time (CVT), point detonating (PD), point detonating delay (PDD), infrared (IR), proximity (VT), and electronically set fuze (ESF).

Mod 1 development began in 1977, and the gun was first tested aboard the destroyer *Briscoe* in February 1980. Production began in 1982 for Aegis cruisers from CG 51 on, for *Arleigh Burke*-class destroyers, and also for the Greek and Turkish MEKO frigates. Selected *Spruance*-class destroyers will have their Mod 0 guns altered to Mod 1 standards.

The manufacturer, FMC, is developing an Advanced Mk 45 mount. It would have a credible future antiaircraft potential, achieved by increasing rate of fire (via modified projectile handling), higher gun elevation and training rates, and better ballistic performance (increased muzzle velocity and tube length). As of 1990, FMC expected to achieve a burst rate of 40 rnds/min (23 rnds/min sustained) and a maximum elevation of 70 deg. It is working on a new lighter-weight gun shield whose profile will minimize radar cross section. FMC also hopes to improve reliability and maintainability, e.g., by simplifying the hydraulics and the electric drives.

5-in/54 Mk 45 mount, USS *Vincennes*, 1987. (W. Donko)

Design model of a Mk 45 Advanced Naval Gun, as envisaged by FMC. (FMC)

◆ 5-in/38 (Twin Mount)

Caliber: 5-in/38 (54-lb shell) **Rate of Fire:** 10–15 rnds/min/gun
Muzzle Velocity: 2600 ft/sec
Maximum Range: 16,500 yd surface; 11,900 slant (time of flight to 10,000 yd at 11-deg elevation: 22 sec)
Training Rate: 25 deg/sec (elevation 15 deg/sec)
Elevation/Depression: +85/–10 deg
Ammunition Capacity: none on mount **Weight:** 95,700 lb
Working Circle: 11 ft 11 in

Twin 5-in/38 mount on board the USS *Iowa*, 1989. Two Phalanxes and 2 quadruple Harpoon missile launchers are also visible. The radome forward of the ship's after funnel houses her RPV control antenna; another is just visible forward of the tower foremast. (J. Kuersener)

The 5-in/38 was the standard U.S. Navy dual-purpose gun of World War II. In very limited service in the U.S. Navy now (twin mounts on board the battleships), 5-in/38 remains on board many ex-U.S. destroyers in other navies. Data above are for the twin destroyer mount, probably the most common surviving type (*Gearing*- and *Sumner*-class destroyers). The weight given is for a 0.125-in shield; with an 0.5-in shield, the gun weighs 105,600 lb. The corresponding battleship mount, with a 2.5-in shield, weighs 169,000 lb. The usual crew for a twin mount, including loaders below decks, was 26 (13 on the mount itself).

A 5-in/38 rocket-assisted projectile (Mk 57) was developed during the Vietnam War. Including cartridge case, the projectile is 51.5 in long and has a maximum surface range of 23,770 yd. The rocket burns for 40 sec, and the shell carries 3.5 lb of explosives. Corresponding figures for the standard 5-in rnd (Mk 66) are 50.14 in, 41.6 lb (shell only), range 14,000 yd, and explosive content 7.9 lb.

The barrel's service life is 4600 rnds. Regunning time is 8 hr/gun, compared to about 1 hr for the 5-in/54 Mk 42 or Mk 45. There are no ready-service rounds on the mount.

◆ 5-in/38 Mk 30

Caliber: 5-in/38 (54-lb shell) **Rate of Fire:** 15 rnds/min/gun
Muzzle Velocity: 2600 ft/sec
Maximum Range: 16,500 yd surface; 11,900 slant (time of flight to 10,000 yd at 11-deg elevation: 22 sec)
Training Rate: 38.74 or 34 deg/sec (elevation 15 or 18 deg/sec) (GE or Ford controls, respectively)
Elevation/Depression: +85/–10 deg
Ammunition Capacity: none on mount
Weight: 40,900–41,400 lb (33,500 lb for the open mount)
Working Circle: 11 ft 11 in

Single enclosed Mk 30 5-in/38 mount aboard the U.S. Coast Guard cutter *Midgett*, 1987. (W. Donko)

This shielded single base-ring mount corresponds to the twin mount described above. In the U.S. Navy, this mount remains on board only FFG 1- and FF 1040-class frigates, which are being transferred abroad. Mk 30 also survives on board many ex-U.S. destroyers and destroyer escorts. Some auxiliaries have open base-ring mounts (Mk 37): 34,700 lb, 30/15 deg/sec training/elevation rates.

◆ 5-in/25

Caliber: 5-in
Shell Weight: 53.85 lb
Muzzle Velocity: 2200 ft/sec
Maximum Range: 14,500 yd; maximum altitude 27,400 ft (dual-purpose version only)
Elevation Limits: +85/–15 deg (+40/–10 deg)
Rate of Fire: 20 rnds/min (max)
Training Rate: 20 deg/sec; 30 deg/sec in elevation (manual: 1.5 and 2.5 deg per handwheel turn, respectively)
Weight: 23,270 lb (14,000 lb)
Working Circle: 121.5 in (99 in) (radius in both cases)

Data apply to the Mk 10 antiaircraft gun in a Mk 27 mount; data in parentheses refer to the wet submarine gun in the Mk 40 mount. Rated life of the gun bore was 3000 rnds (as reported in 1944).

These guns are survivors of a once-numerous group of weapons. Unlike the 5-in/38, the 5-in/25 fires a fixed round, just at the limit of quick handling by a single person. The 5-in/38 was developed from the 5-in/25 by increasing cartridge weight (hence muzzle velocity) for better surface performance. Both versions of the 5-in/25 are semiautomatic guns with vertical sliding-block breechblocks.

There are 2 types, an antiaircraft gun that survives on board the Chilean cruiser *O'Higgins*, and a wet submarine gun that survives on board several Peruvian submarines built in the United States. In addition, U.S. World War II-built fleet submarines, including those subject to "fleet snorkel" conversion, retained provision to mount one or two 5-in/25 wet guns. Guppy conversion presumably entailed streamlining to the extent that external gun foundations were eliminated, but the supporting structures below decks survived. Although no ex-U.S. submarines currently mount 5-in/25 guns, it seems likely that navies possessing such submarines retain these weapons and can mount them for special purposes, as the Royal Navy mounted 4-in guns on board its own streamlined submarines during the confrontation with Indonesia.

◆ 3-in/50

Caliber: 3-in/50 (15-lb shell) **Rate of Fire:** 45 rnds/min/barrel
Muzzle Velocity: 2700 ft/sec
Maximum Range: 14,600 yd (time of flight to 6000 yd at 5-deg elevation: 12 sec) Maximum altitude is 30,400 ft.
Training Rate: 24 deg/sec (elevation 30 deg/sec)
Elevation/Depression: +85/-15 deg
Ammunition Capacity: No ready-use ammunition on mount (but each barrel can have 5 rnds in its loader). Typically 200 or 300 rnds in ready-service locker, another 1200 in magazine.
Weight: 31,435-32,400 lb, depending on version
Working Circle: radius 120 in

Enclosed 3-in/50 mount Mk 33 on board the USS *Tuscaloosa*, 1987. (W. Donko)

Twin 3-in/50 mounts, with the dishes of SPG-34 radars atop them. The associated Mk 63 directors were mounted separately. (U.S. Navy)

Data are for the twin automatic 3-in/50 Mk 33, once very widely used in the U.S. Navy and in several other navies. This weapon was developed specifically to deal with kamikazes; in 1945 it was the smallest gun that could fire a proximity-fuzed shell. Although there is no magazine as such on the mount, the loaders continually refill the 5-rnd revolving loading drums that actually feed the guns. There is no rammer as such; instead the loader, which is an independent electrically driven device, catapults each round into the chamber, the breech-closing mechanism being triggered by the edge of the cartridge case as it trips one of the ejectors. Once a round is in the breech, the loader cycle is stopped until the gun fires and ejects that cartridge case.

This unusual arrangement was adopted because the gun itself is the earlier semiautomatic weapon adapted as simply as possible to automatic fire; in effect the loading and triggering cycle has been automated, without any basic redesign. That simple automation in turn limits the ultimate rate of fire. Because firing is automatic once a round has been catapulted into the chamber, the gun is unloaded whenever it is not firing: the loader has 6 slots, but only 5 can be occupied.

The original version of the twin automatic mount was Mk 27; Mk 33 is more common. Many mounts are enclosed in fiberglass gunhouses. There is also a single version (Mk 34), weighing, typically, 17,000 lb.

The barrel's life is 2050 rnds.

This gun is usually controlled by a Mk 56 director; others, with a Mk 34 (SPG-34) radar dish on the mount, are controlled by the Mk 63 system. Except for 2 escorts (the FF 1037 class), the U.S. Navy has removed all remote FCSs for these weapons from its ships, leaving the guns entirely locally controlled.

The 3-in/50 automatic gun was initially provided to Japan under the Military Assistance Program (MAP). From 1957 on the gun was manufactured under license by the Japan Steel Works.

Some surviving World War II ships (2 in the U.S. Navy) and many coast guard ships are armed with the earlier single semi-automatic 3-in/50 mount (Mk 26) from which this weapon was derived; Mk 26 has the same ballistics. Its rate of fire is 15-20 rnds/min, and because of the slower rate of fire, the barrel's life is rated as 4300 rnds. The working circle's radius is 96 in.

◆ 3-in/62 Mk 75

Caliber: 76-mm/62 **Rate of Fire:** 80 rnds/min
Muzzle Velocity: 3000 ft/sec
Training Rate: 65 deg/sec (elevation 35 deg/sec)
Elevation/Depression: +85/-15 deg
Ammunition Capacity: 80 (ready-service)
Weight: 16,500 lb above decks; 763 lb below decks
Working Circle: radius 208 in

Mk 75 3-in/62 gun on board the USS *Fahrion*, 1984. (A. Raven)

This U.S. version of the Italian OTO-Melara 76/62 is manufactured by FMC (and by OTO-Melara itself since FY86) and mounted on board U.S. frigates and missile hydrofoils and Saudi patrol craft. This gun, generally controlled by a Mk 92 FCS, is manned by 3 enlisted. Compared to the 3-in/50, the 3-in/62 carries a much larger supply of ready-service ammunition, allowing the gun to fire long bursts without reloading. Because it is very nearly unmanned, it can fire at very short notice. The muzzle brake reduces recoil by about 35%. There is also a tank-type bore evacuator. Compared with a 5-in gun, this weapon's one great defect is that it cannot fire any of the more sophisticated munitions.

The gun can be arranged to use 1, 2, or 3 loading drums (40, 80, or 115 rnds). Rounds pass up a hoist, from which they are

stripped by a pair of rocker arms. The arms in turn feed a revolving 4-rnd feeding drum above the loading tray. The tray pivots back and up to strip a round from the loading tray, then moves into alignment with the breech so that the round can be rammed. As in the Mk 42 mount, 2 rocker arms are needed to maintain a high rate of fire, 1 swinging up while the other swings down.

The 3-in/62 is manufactured under license in Japan (by the Japan Steel Works).

◆ 81-mm Mortar Mk 2

Caliber: 81-mm (53 lb for package of 3 rnds)

Muzzle Velocity: 787 ft/sec

Rate of Fire: 10 rnds/min trigger; 18 rnds/min drop-fire, 45-deg elevation

Maximum Range: 3987 yd

Elevation/Depression: +71.5/-30 deg **Working Circle:** 108 in

Over-and-under 81-mm mortar and 0.50-cal machine gun on board a patrol boat in Panama, 1983. (U.S. Navy)

This weapon can be mounted alone or in combination with a 0.50-caliber M2 machine gun, in a piggyback mount. In contrast to mortars for land service, this mortar is either trigger- or drop-fired, and it can, therefore, be fired at 0 elevation. Mk 2's recoil mechanism reduces deck loads when the gun is fired. Mk 2 uses army ammunition.

Mod 1 is the piggyback version carrying the 0.50-caliber machine gun; total weight is 722 lb.

◆ 60-mm Mortar

Caliber: 60-mm (49 lb for package of 10 rnds)

Muzzle Velocity: 500 ft/sec

Rate of Fire: 10 rnds/min trigger; 18 rnds/min drop mode, 45-deg elevation **Maximum Range:** 1850-2000 yd

Elevation/Depression: +80/-20 deg **Working Circle:** 114 in **Weight:** 177 lb

This mortar is a smaller version of Mk 2. Although rarer than Mk 2, it remains in U.S. service; some have seen service in the Persian Gulf on board patrol boats (PBs). During the Vietnam

War it was used on board PBRs, which could not accommodate the 81. In many cases it is combined with an M60 machine gun in a piggyback combination. The 60-mm mortar is descended from Mortar Mk 1, the Garrett (Kodak) trigger-fired mortar of 1945.

◆ 40-mm Guns

Caliber: 40-mm/56.3 (1,985-lb shell) **Rate of Fire:** 160 rnds/min

Muzzle Velocity: 2890 ft/sec

Training Rate: 24 deg/sec (elevation 30 deg/sec)

Elevation/Depression: +90/-15 deg

Weight: 24,900 lb (13,000-14,000 lb)

A quadruple 40-mm mount on board the cruiser *Portland*, 1944. Although the ship is long gone, some of these mounts survive. The boxes cover the paired feeds of the 2 guns. (U.S. Navy)

The new single 40-mm mount Mk 3 Mod 9, on board a 65-ft Patrol Boat Mk 3. The object above the gun is the autoloading magazine. (U.S. Navy)

The U.S. Navy developed 3 principal Bofors mountings: a water-cooled twin mount (Mk 1), a quadruple (dual-twin) mount (Mk 2), and an air-cooled single mount based on the army's version of the gun (Mk 3). Mk 4 was a lightweight quadruple mount produced in small numbers in 1945. Very few of these weapons remain in U.S. service, but they were widely exported. Data above apply to the quadruple mount (twin mount data in

parentheses). The only Mk 2s remaining in U.S. service are 2 on board the *Sphinx* (ARL 24), controlled by 2 Mk 51 Mod 2 FCSs.

Mk 3 was originally a hand-operated gun for submarines and PT boats, but many of these guns were converted to power drive (4200 lb rather than the original 2440 lb, with performance comparable to Mk 1 and 2, above).

Mk 3 Mod 9 is a rebuilt single army-type gun for 1-crew operation on board patrol craft. This version is power-operated and stabilized and autoloading (48-rnd magazine). The first 2 were converted, by an ordnance depot, under the FY82 program. These guns were installed on board 17 PB Mk III Sea Spectre patrol boats. Their loading drums were usually removed because they interfered with vision from the pilot house. This weapon is being replaced by the 25-mm Mk 88 Bushmaster described below.

◆ 40-mm Grenade Launcher Mk 19

This short-range machine gun is used on board riverine and coastal craft and on larger ships to defend against saboteurs and boarders. Operation is by blow back, and the gun fires 400–450 rnds/min at a muzzle velocity of 800 ft/sec. Maximum range is 2400 yd (35-deg elevation), and effective range is 1780 yd (15-deg elevation). A 24-rnd box of ammunition weighs 21.5 lb.

Mk 19 was developed during the Vietnam War and remains in production.

There was also a family of shorter-range grenade launchers, with a muzzle velocity of 215–230 ft/sec (maximum range 385–440 yd, effective range 350 yd): Mk 18 and Mk 20, rate of fire continuously variable from single shot to 250 rnds/min. These launchers were effectively rapid-fire versions of the army's M79 grenade launcher. Like Mk 19, they were externally powered.

◆ EX-74/Emerlec-30

Caliber: 30-mm **Rate of Fire:** 1100 rnds/min (selectable rate)
Muzzle Velocity: 3543 ft/sec **Maximum Range:** 3500 yd
Training Rate: 90 deg/sec (elevation 80–85 deg/sec)
Elevation/Depression: +80/–15 deg
Ammunition Capacity: 985 rnds/gun
Weight: 3469 lb (full system 4156 lb without ammunition)
Working Circle: 88 in

Emerlec-30 gun mount. (Emerson Electric)

This Emerson Electric mount carries one 30-mm Oerlikon gun on each side of a cab in which the operator sits. EX-74 was originally developed for the U.S. CPIC coastal-patrol boat (of which only a prototype was ever built), but a developed version of the mount was later very successfully exported, as the Emerlec-30, to Ecuador, Greece, Malaysia, Nigeria, the Philippines, and South Korea. As of January 1988, over 150 Emerlec-30s had been delivered. The principal difference between the U.S. Navy's version and the exported version is that the navy's gun did not penetrate the deck, whereas export guns have below-decks magazines.

Emerlec-30's characteristics generally follow those above, but the claimed rate of fire is 1200 rnds/min and weight without ammunition is 4200 lb. Working circle is 94 in. Training rate is 80 deg/sec (elevation 80 deg/sec). The gun is an Oerlikon (Hispano-Suiza) 30-mm cannon, with a barrel life of about 5000 rnds.

In the U.S. CPIC, the Emerlec-30 was controlled by GFCS Mk 93, which incorporated the Kollmorgen Mk 35 periscope director.

◆ EX-83

This powered mount carries a 30-mm GAU-8/A Gatling gun. EX-83 forms the basis of the Dutch Goalkeeper close-in weapons system and was proposed as the basis of the French Satan system. The Dutch selection of the EX-83 mount was apparently based on successful trials at Den Helder early in 1980, using an EX-83 controlled by a Signaal Flycatcher radar tracker (which is similar to STIR and thus to the VM40 proposed for Sea Wolf missile control). Success in these tests demonstrated both the pointing accuracy of Flycatcher and the tight dispersion of the 30-mm gun.

These tests were for land-based air defense, but they were clearly applicable to the naval close-in defense problem.

EX-83 is also the basis of the French SAGEM and SAMOS. There was also a proposed VSEL (Vickers) Sea Dragon carrying a Marconi tracker radar above the gun mount proper (1983), and there was a projected Israeli version. The U.S. Navy tested the EX-83, controlled by the Mk 86 FCS, on board the destroyer *Merrill* (DD 976) in 1981. For details of the EX-83 gun and mount, see the Goalkeeper entry above.

◆ 25-mm Automatic Cannon Mk 38 (Bushmaster)

Caliber: 25-mm/87 (1.1-lb round) **Muzzle Velocity:** 1100 m/sec
Rate of Fire: single shot, 100, or 200 rnds/min
Training Rate: manual mount **Maximum Range:** 6800 m
Elevation/Depression: +55/–20 deg
Ammunition Capacity: 150 linked cartridges
Weight: total gun weight (no mounting) 240 lb; total mounting weight 1250 lb

Bushmaster is the naval version of the "Chain Gun," an externally powered weapon developed by Hughes for the U.S. Army. The Chain Gun was originally a 20-mm, then a 30-mm (Aden ammunition) gun firing linkless ammunition at up to 900 rnds/min. Procured by the army as M242, the gun is designated Mk 38 for naval service; the pedestal mounting, Mk 88. The 25-mm gun is credited with a barrel life of 25,000 rnds; dispersion is 0.5 mil.

The name derives from the use of a loop of standard industrial double-row roller chain, carried horizontally, to drive the bolt back and forth. The length and width of the chain are determined by the length of the round and by the desired rate of fire. The chain runs at constant speed, carrying a shoe that drives the bolt. When in line with the bolt, the shoe pulls back and forth, locking and opening the bolt. When the shoe travels to one side (along the belt, perpendicular to the gun's axis), the gun has time to fire or to eject a fired cartridge (depending on where in the cycle this travel occurs). The feed to the gun is powered by the same motor that drives the chain.

Development and procurement of the Chain Gun were originally approved in December 1971. In 1977 the chief of naval operations approved procurement to replace existing obsolete

25-mm Bushmaster (Mk 38 gun on Mk 88 mount). (McDonnell Douglas Helicopter Co.)

A Bushmaster on board the *Mount Vernon* in the Persian Gulf, October 1987. (U.S. Navy)

Mk 16 20-mm guns, which were difficult to support (they required overhaul every 6500 rnds) and did not use standard NATO ammunition; many existing rounds were considered unsafe.

This weapon, already in large-scale production for the army, was operationally evaluated for naval use in the summer of 1987, and by mid-1988 over 5000 had been delivered to the U.S. Army. Bushmaster replaces existing U.S. Navy 20-mm cannon. The Mk 88 mount is not stabilized and is hand-aimed; it cannot, therefore, make very many hits when mounted on a lively small combatant. As of mid-1988, many Mk 88s were in service in the Persian Gulf, and they also equipped the Mark 4 patrol boats in the Panama Canal Zone. As of August 1988, the Naval Sea Systems Command planned to buy 460 Mk 88s.

Production of Mk 38 25-mm cannon was drastically accelerated in 1987-88 to meet the needs of ships in the Persian Gulf, much of the work being done at NWSC (Naval Weapons Support Center) Crane (which was responsible for the design of the gun's Mk 88 mount).

In 1989 the Chain Gun manufacturer, McDonnell Douglas Helicopters (the former Hughes helicopter division), announced a new series of weapons using the same principle:

- 20-mm Pit Viper (an entry into LHX armament competition, to be fired for the first time in December 1989, with a maximum rate of fire of 800 rnds/min, and with 25,000 MRBF.
- 30-mm Bushmaster II (which had already fired 500 rnds as of late 1989, and which was due for Austrian (AFV) and U.S. Navy (2000 rnds) tests during 1989. It fires

standard GAU-8 ammunition or, modified, RARDEN or KCB ammunition. 70% of the parts of this gun are the same as those used in the Bushmaster. Rates of fire are single shot, 200, or 400 rnds/min. Possible applications include the Minor Caliber Weapons Station being developed by AAI (see entry below).

- Bushmaster III, which can fire 35-mm or 50-mm rnds with minor changes (including a barrel change). As of late 1989, first firing was due in July 1990 in 35-mm configuration.

◆ L-CAT 25

Caliber: 25-mm **Training Rate:** 80 deg/sec (elevation 60 deg/sec)
Maximum Range: 3000 m (effective range)
Elevation/Depression: +60/-20 deg
Ammunition Capacity: 400 rnds **Weight:** 1500 lb empty
Working Circle: diameter 130 in

Emerson's single stabilized 25-mm gun mount, suitable for small patrol boats, was announced in 1984. It was developed as a result of a U.S. Navy project to define the characteristics of a standard minor-caliber mount. Empty weight is less than 680 kg, and the mount bolts to the deck. Control may be either manual or remote. Drive is electric rather than hydraulic, for simpler maintenance.

Data above refer to the remotely controlled 25-mm mount carrying the M242 Bushmaster. In the manned version, the gunner replaces one of the two 200-rnd ammunition boxes. This mount can also carry the Oerlikon KBA (570 rnds/min), which has about 3 times the recoil force of the M242.

Only a prototype was built, but L-CAT is interesting as an approach to the problem of installing guns on small combatants. At the 1986 Italian naval exhibition (Mostra Navale), Oerlikon Italiana showed a scale model of the mount, carrying a 25-mm KBA. The company was trying to interest the Italian navy in license production, on the theory that 25-mm guns would be attractive to many navies, to arm small combatants, but that most of the combatant operators would find a stabilized mount much more attractive than the standard unstabilized Mk 88.

The U.S. Navy tentatively assigned a Mk 89 designation to this mounting.

◆ Sea Vulcan 25

Caliber: 25-mm **Muzzle Velocity:** 3400 ft/sec
Rate of Fire: selectable, 750 or 2000 rnds/min
Training Rate: 1.6 rad/sec (train and elevation)
Ammunition Capacity: 500 rnds
Elevation/Depression: +85/-25 deg
Working Circle: radius 64.0 in **Weight:** 2800 lb fully loaded

General Electric's private-venture gun mount carries the lightweight 5-barrel 25-mm aircraft Gatling gun (GAU-12/U). Sea Vulcan was proposed for the abortive SWCM (surface-effect SEAL delivery craft), rejected, then restored to the program before the SWCM program itself died. The mount may appear on future U.S. small combatants, e.g., on whatever SWCM replacement emerges. Compared to the present 25-mm Bushmaster, Sea Vulcan 25 offers a much higher rate of fire and, more importantly, a stabilized line of fire suited to lively small craft. The mount was very successfully tested in 1987 on board the SES-200 surface-effect boat. The power-driven mount can incorporate an IR camera for accurate target tracking or can be controlled by a lightweight off-mount director. Although the version tested in 1987 carried only the 25-mm gun, full-size models displayed in the past have carried 2 Stinger missile tubes.

General Electric claims that Sea Vulcan 25 can kill targets, presumably corresponding to a small missile, at 2000 m (it has published a photograph of the destruction of a Lynx drone at 500 m). In tests, Sea Vulcan was controlled by a Mk 24 optical director and an electro-optical director. Dispersion is 2.23 mrad. Claimed reliability is 7000 MRBF or 200 hr MTBF (nonfiring).

In the form planned for the SWCM, this mount was tentatively designated EX-90.

Sea Vulcan 25. (General Electric)

◆ Zenith 25/30

This projected General Electric turret on a canted mount is similar in concept to the Sea Zenith employed in the Swiss Seaguard system but carries a 25-mm GAU-12/U (as in the AV-8B) or a 30-mm GAU-8 gun. Zenith was announced in 1982. Sea Zenith was proposed either as main armament for a small combatant, or as the gun element of a ship's close-in defensive weapons system.

Sea Zenith. (General Electric)

In Zenith 25, the ammunition feed has been modified so that it can operate (at 2000 rds/min) at any angle of gun elevation. The manufacturer hopes to increase this rate to at least 3000 rds/min, or to 4000 by scaling down the linkless feed of the GAU-8. Total weight is 4000 lb, and the training/elevation rate is 1.6 rad/sec. Working circle radius is 68 in (base radius 36 in).

◆ AAI Naval Gun Mount

AAI Corporation is developing a naval version of the Minor Caliber Weapons Station (MCWS) under development for U.S. Marine Corps vehicles. This version will be electrically driven, with 2- or 3-axis stabilization, and will carry a 25-mm or 30-mm gun, plus perhaps a Stinger-missile launcher. Elevation limits will be -8 to $+60$ deg (slew rates up to 60 deg/sec), and the mount will carry 400 rds of 25-mm ammunition, or 150 to 200 rds of 30-mm, plus up to 2 twin-rail missile launchers. AAI proposes 2 configurations: through-deck (2200 lb) and above-deck (2500 lb), each with 100–500 lb of remote-control equipment and displays. Possible applications include future small combatants and landing craft.

As of early 1989, the AAI gun mount was being tested aboard a navy SWATH (presumably the *Kaimalino*) off Hawaii. The Military Sealift Command was showing interest in a modular version that could be stored ashore and then installed aboard ships in an emergency. MCWS was originally designed specifically for the Marine Corps and was tested on an AA-7 in late 1988.

AAI naval gun mount. (AAI)

◆ ASP 30

Caliber: 30-mm/49
Rate of Fire: single shot/400–450 rds/min
Muzzle Velocity: 2750 ft/sec
Maximum Range: effective range 2 km [2200 yd]
Weight: 105 lb

This McDonnell Douglas Helicopters (formerly Hughes Helicopters) automatic cannon, announced in 1989, is only slightly larger than the standard Browning M2HB 0.50-caliber machine gun and has little more recoil, thanks to a muzzle brake and 2 hydraulic dampers. It can, therefore, fire ADEN 30-mm ammunition from the same type of simple pedestal mount typically associated with the 0.50. In comparison to the figures above, the M2HB weighs 84 lb and is 65 in (rather than 79.8 in)

long; it fires at about the same rate and has a muzzle velocity of 2930 ft/sec. The barrel length quoted above for the ASP 30 includes the blast suppressor.

In 1989 Royal Ordnance bought the rights to market ASP 30 throughout the world, apart from the United States. At RNEE 1989 it quoted a unit price of £ 25,000. Likely applications include fast patrol boats and light vehicles ashore. Ammunition is HE, AP, or multipurpose (presumably Raufoss-type).

◆ Phalanx (Close-In Weapons System Mk 15)

Caliber: 20-mm/76 (0.22-lb round)

Rate of Fire: 1000–3000 rnds/min **Muzzle Velocity:** 3650 ft/sec

Maximum Range: 6000 yd (effective range 1625 yd)

Training Rate: 100 deg/sec (elevation 86 deg/sec)

Elevation/Depression: +80/–20 deg **Ammunition Capacity:** 989

Weight: 12,000 lb above deck, 466 lb below deck

Working Circle: diameter 216 in

Phalanx is the standard U.S. Navy close-in weapons system, using bursts of depleted-uranium penetrators to destroy or fuze incoming antiship missiles. The weapons system's designation covers the mount plus integrated radar; the mount proper is Mk 72.

Phalanx combines a 20-mm Vulcan automatic cannon with a (search and track) Ku-band radar that has 2 antennas but 1 transmitter. The radar automatically detects and tracks incoming missiles. In the search mode, the radar uses unambiguous doppler/ambiguous range, switching PRF to achieve range resolution in 3 range-coverage zones. During target acquisition, the system again uses unambiguous doppler/ambiguous range and a derived search range, bearing, and speed to search a "basket" provided by the search radar. Normally there is no operator intervention: the system decides automatically to engage, and the operator has a veto.

When the gun begins to fire, the radar also tracks outgoing

Phalanx. (General Dynamics)

Phalanx (Close-in Weapons System Mk 15). The drum magazine is under the gun. (U.S. Navy)

bursts of fire, predicts their point of closest approach to the incoming target, and corrects the aim of the following burst(s). This electronic spotting uses variable PRF with selected spectral (frequency) line tracking to measure the projectile stream's angular error. The manufacturer, General Dynamics, claims that this closed-loop spotting system improves lethality by as much as an order of magnitude. This self-contained FCS was originally designated Mk 90, although that designation has been dropped in favor of the Mk 15 designation embracing the entire system.

Phalanx was designed so that it can be rigged to engage surface targets designated by conventional optical target designators. However, that configuration is officially discouraged; ships are expected to use dedicated light guns, such as single 20s or Bushmasters, for self-defense against small surface craft.

This system was first proposed in 1968 as part of the early antiship-missile defense program prompted by the *Eilat's* sinking; a feasibility contract was awarded to General Dynamics in 1969. The first closed-loop spotting system was demonstrated at White Sands in 1970, and a prototype was demonstrated on board the missile destroyer *King* in 1973. There were, however, doubts as to whether Phalanx could destroy incoming cruise missiles. They were resolved, and full-scale production was authorized in 1977, the first installation (on board the carrier *America*) following in 1980. The 400th system was delivered in 1985.

Some indication of Phalanx's performance is given by characteristics as projected in 1971. At that time Phalanx evaluated targets it detected in terms of range, range rate, and sector. It scanned between 0 and 5 deg in elevation (external designation

CIWS Block 1, showing the new upper [search] antenna and the enlarged magazine. (General Dynamics)

was needed for any target at a higher elevation). It was expected to detect a target at 5600 yd, acquire it at 4300, and open fire at 2500 (1st potential intercept at 2000). The inner boundary (keep-out zone) was defined as 100–230 yd. The closed-loop spotter tracked the centroid of 6 projectiles at a time. The slewing rate was 1.75 rad/sec [100.3 deg/sec] with an acceleration rate of 10.5 rad/sec/sec [601.7 deg/sec/sec].

Some difficulties were encountered in service. Block 0 guns suffered from sea corrosion, a problem corrected by construction of special "maintenance shelters" around parts of the mount. In addition, it takes 10–30 min to reload the ammunition drum.

Phalanx Block 1 (authorized for limited production in 1986) provides 50% more on-mount ammunition. This version is also designed to engage diving targets at steeper angles. The 2D scanning antenna of Block 0 is replaced by a 4-plate back-to-back antenna that continuously searches up through the zenith. In addition, a positive cease-fire function matches burst length to target characteristics, to conserve ammunition so that more targets can be engaged before reloading. Current developmental work is intended to counter faster, lower-altitude maneuvering targets with reduced radar cross sections. Block 1 was operationally tested at China Lake 3 December 1981–21 May 1982.

Block 1 deliveries began in January 1988; the first 4 were installed on board the *Wisconsin*. A new upgrade (a pneumatic gun drive) now in production increases rate of fire from 3000 to 4500 rnds/min, and further improvements are being investigated.

At the 1989 U.S. Navy League Show, GE displayed a new Phalanx Magazine Loading System, by means of which 2 gunners can reload a mount in less than 5 min, compared to 30 min at present. It uses a second ammunition drum, mounted on top

of the electronics enclosure, feeding rounds into the main drum when the latter is empty.

As of early 1990, the navy is shifting from depleted-uranium to tungsten penetrators. In nearly 700 test shots, the latter turned out to penetrate missiles and hit their guidance systems with greater mass intact. There was also concern about depleted-uranium handling problems; the material is mildly radioactive and must, therefore, be handled with gloves. When it is stowed adjacent to berths, the latter must be protected with lead. Until recently the higher cost of tungsten precluded any change, but now tungsten costs less than uranium. Tungsten accounted for 20% of the rounds bought in 1989 and will be 100% in 1990, although the navy's interest in depleted uranium persists.

Phalanx Block 1 (CIWS Mk 15 Mods 11–14) is now being improved. Baseline 0 was approved for limited production in FY85 and entered service in October 1988. It provides increased performance in search-elevation coverage, increased velocity coverage, a larger magazine, augmented reliability, BITE, and better system-operability test (SOT) and fault-isolation test (FIT) programs. Block 1 Baseline 1 adds a pneumatic gun drive (4500 rnds/min) and increased search sensitivity. It was approved for limited production as part of the FY88 and FY89 production lots; it is to be approved for full production in FY90. Work is currently underway on Block 1 Baseline 3, which is to undergo initial operational test and evaluation in FY91. Block 2, to enter service about the year 2000, will probably use a new gun, either GE's twin 25-mm or the Tround 25-mm. This weapon has also been referred to as CIWS-2000.

In August 1990 NSWC circulated a request for information on 3–5-micron sensor/trackers suitable to acquire antiship missiles at useful ranges. Reportedly, GE is already working on a Phalanx upgrade incorporating an IR sensor or an electro-optical adjunct. There is also speculation that the navy is considering a Phalanx upgrade in which the radar would be moved away from the gun proper; the radars apparently suffer from gun heat, smoke, and flash.

In 1983 a modified Phalanx, carrying a 4-barrel 30-mm GAU-13 gun, was proposed for the Royal Navy. The Signal Goalkeeper was chosen instead, but the proposal shows to what extent the existing Phalanx could be up-gunned (re-equipped with a more powerful gun) with minimum modification. In 1988 it was reported that General Dynamics was considering 2 up-gunned versions of Phalanx, 1 with a 4-barrel 30-mm gun and 1 with twin 25-mm guns.

In 1987–88 the follow-on system was nominally designated CIWS-2000. In January 1988 a congressional conference committee refused further funding for CIWS-2000 until the U.S. Navy had evaluated Goalkeeper. Admiral Metcalf, the outgoing chief of surface warfare, had already tried to cancel CIWS-2000 in the fall of 1987, arguing that the system represented an insufficient advance over the existing Phalanx, and that more revolutionary, rather than evolutionary, counters to attacking missiles were needed. That argument may reflect interest in such exotica as chemical lasers and directed-energy weapons.

GE has proposed a new cased telescoped (CT) 25-mm gun as a next-generation Phalanx weapon. Two such guns would fire up to 12,000 rnds/min, and a mount might accommodate up to 2600 rnds. The CT round, developed under an air force contract, is shorter than a conventional round and, therefore, allows for a more compact gun. A 20-mm prototype has fired over 6000 rnds successfully (and is more reliable than a conventional 20-mm Gatling), and GE expects the basic CT mechanism to have 67% fewer parts than an existing weapon. Estimated reliability is 50,000 rnds between failure, and system life should be 250,000 rnds. Estimated system dispersion is 1.1 mrad, and muzzle velocity should be 3700+ ft/sec. The gun would use a new linear linkless feed system.

Should tests prove successful, the Rockwell dual-band radar being developed for TASD (see the separate entry) may replace the current Phalanx radar. Its main advantage is that it promises to solve the multipath and glint problems.

♦ Sea Vulcan 20 (EX-84)/20P

Caliber: 20-mm **Rate of Fire:** 750/1500 rnds/min
Muzzle Velocity: 3380 ft/sec
Training Rate: 80 deg/sec (elevation 60 deg/sec)
Elevation/Depression: +55/-10 deg
Ammunition Capacity: 500 rnds **Maximum Range:** 6000 yd
Working Circle: 130 in **Weight:** 318 kg empty, 465 kg loaded

Data apply to Sea Vulcan 20.

Sea Vulcan 20 is a powered turret mount for a 3-barrel M197 Vulcan machine gun, for use on small craft. The turret itself is also designed to carry the 7.62-mm mini- (Gatling) gun and the M19 40-mm grenade-launching machine gun. Many components are identical to those used in the UTS turret of the AH-1 attack helicopter. The system is remotely controlled with its own on-board ballistic computer (to process target-designation data from another source). One EX-84 mount was built and tested in June 1981 on board a U.S. PB Mk III, but the weapon did not enter U.S. service.

A Sea Vulcan 20 was mounted on board the Thai Hyuscat-18

Sea Vulcan 20 on board the Thai Hyuscat-18 fast patrol boat. (Tecnautic)

General Electric has proposed a 25-mm cased telescoped (CT) gun as the next-generation upgrade to Phalanx.

A JM61-M Vulcan mounting on board a Japanese minesweeper. (Sea Power)

patrol vessel, controlled by a Kollmorgen Mk 35 periscope director. Total weight was 800 lb empty or 1167 lb with ammunition, and training and elevating rates were 60 and 50 deg/sec, respectively. As installed on board the Thai patrol boat, the mount also carried a mock-up of a 2-missile SAM launcher on an extension of the elevation gimbal shaft. The mount could carry Stinger, Mistral, Blowpipe, Javelin, or RBS 70. This mount (less the missiles) was retrofitted into existing Honduran navy patrol craft (85-, 105-, and 106-footers) in 1986-87. In addition, 2 Sea Vulcans were installed on board the Boeing commercial Jetfoil operating as tender to the larger Saudi royal yachts. The hydrofoil is also armed with Stingers.

Sea Vulcan 20P is a much simpler pintle mount (originally designed to carry a twin 20-mm cannon) carrying the same 3-barrel gun and a 300-rnd ammunition box. Total weight is about 500 kg without ammunition, and elevation limits are +75/-10 deg. Although this mount is not in U.S. service, it has been bought by the Japanese Maritime Self-Defense Force. The South Korean navy uses this gun in its own specially weatherproofed mounting.

Both the gun and the Sea Vulcan mount are manufactured by General Electric.

◆ Tround

Tround is a new rapid-firing breechless gun that may ultimately replace the current Gatling. Each bullet is encased with its propellant in a triangular plastic or composite shell; shells are fed into triangular notches in a rotating cylinder. When the notch reaches the firing position in front of the single barrel, a strap comes down to hold it in place. The cartridge case replaces the breech enclosure of a conventional gun, and it is dropped into its notch rather than being rammed forward into a cylindrical breech. As a consequence, gun operation is quite simple and can be quite rapid. Because the gun uses a single fixed barrel, it does not suffer from the vibration (and consequent inaccuracy) of Gatling guns. Because the cylinder represents a smaller fraction of overall gun mass, it has less inertia than the rotating structure of a Gatling and, thus, can accelerate more quickly to maximum firing rate. The lighter cylinder and very simple firing cycle should also make for a higher rate of fire.

Tround might be considered a further application of the revolver principle used in several airborne cannon, with the important advantage of needing no reciprocating case extractor (see the discussion of the Mauser BK 27 in the Strike/Surface Warfare section).

In June 1989 the U.S. Navy awarded Tround International of Phillipsburg, New Jersey, a 3-yr, \$5.8 million contract to develop a 25-mm breechless gun and triangular round ammunition for it. The contract requires a minimum demonstrated rate of fire of 5000 rnds/min. The company demonstrated the Tround principle in a 0.50-caliber single-barrel version at China Lake in 1986; it achieved 2000 rnds/min. The next stage is a twin-barrel, 4000-rnd/min version. A British firm, Lucas Aerospace, has mounted the single-barrel version in a helicopter gun turret. The U.S. Naval Air Systems Command is currently considering 0.50-caliber and 20-mm Trounds.

A critical design review was scheduled for July 1990; it was to determine whether the Phase Two option, for a 4-barrel Tround gun, would be exercised. Phase Three would be integration into an operational naval system, such as Phalanx.

Tround International was formed in 1981. Initially, it applied what it calls open-chamber technology to mineral drilling (drill guns); the same technology is used in the machine gun. Other applications include nail drivers, fasteners, and engine starters. It obtained its first U.S. Navy contract in 1984, and in 1987 began work on 3 advanced versions: a gun for the Advanced Aircraft Program (which was later canceled), the Lucas Aerospace project for a 20-mm V-22 gun, and an agreement with Kollsman Instrument on a 30-mm Navy Advanced Minor Caliber Gun Program weapon.

◆ AMCGS

Advanced minor-caliber gun system is a projected replacement for the current 25-mm Bushmaster. Tentative specifications were circulated in mid-1990, calling for a 30-40-mm gun system to detect and kill small boats. The Bofors Trinity is a contender. This program is parallel to SWP (see below); draft RFPs were issued for both on the same day. In theory, the gun chosen under AMCGS will be carried in an SWP mounting, although the Bofors Trinity would seem to combine both requirements.

◆ Crossbow

See the detailed description under Strike/Surface Warfare. Crossbow was derived from LTV's unsuccessful entrant for the Stinger missile mounting in the U.S. Army's ADATS competition (see the Swiss section for Oerlikon's successful ADATS). As of September 1990, it had attracted interest both from the U.S. Navy and from 2 foreign navies. It was tested on board a U.S. surface-effect craft in the fall of 1989 and also on board a Swedish *Hugin*-class attack boat carrying RBS-70.

Crossbow at Farnborough, 1990, carrying a pair of 2.75-in rocket pods and 4 RBS-70 missiles. [Author]

◆ SWPS

Stabilized weapons platform is a U.S. Navy program for a short-range weapon to attack small fast attack boats. The weapon is to be carried either by a future patrol boat or on board a larger ship. SWPS was conceived for a future large patrol boat and was originally tied to the projected large SEAL boat (the successor to the abortive Sea Viking). A new SEAL/patrol boat, just ordered from Bollinger, is to be the prototype for a new series, 17 of which were initially planned. The RFP was originally scheduled for release in February 1989; as of September 1990, it was expected by 1 October. One possibility is the LTV Crossbow carrying a 25-mm cannon, missiles, and 2.75-in rockets to deal with area targets on the water. The other main competitors are the AAI gun mount and the Boeing SWPS. As of September 1990 the expected number of mounts had just been increased from 33 to 54, although there was some question as to whether the extra 21 could be funded. The patrol boats now on order will initially be armed with 25-mm Bushmasters, then rearmed later with the SWP carrying the new minor-caliber gun (see AMCGS, above). The requirements figures suggest that each boat will be

armed with 3 of the new weapons. This program is being run by PMS-300, with technical assistance from the Naval Weapons Station at Crane, Indiana.

◆ SWPS (Boeing)

Boeing's stabilized weapons platform system, announced in 1990, is roughly equivalent to the LTV Crossbow and is presumably intended for much the same mission. It consists of a gyro-stabilized deck mount carrying up to 1500 lb of weapons, with a maximum weight of 3300 lb, controlled from a remote system operator's console (SOC). SWPS would probably carry a FLIR, an LLLTV, and a laser range-finder. The SOC's automatic video tracker (AVT) would lock onto a FLIR or LLLTV image (the SOC has a single 8-in screen, with 3 FOVs: narrow, wide, and rain mode to enhance the target area in high seas or bad weather) and would control the SWPS servos. Laser ranges would be displayed directly on the SOC and would be used to determine which weapon is appropriate to a given target, and then to determine when to open fire. The laser can also be used to guide Hellfire missiles. Each of 2 side-mounted launchers can accommodate 2 Hellfires or 4 Stingers or a 2.75-in rocket pod (7 or 14 rockets) and 4 Stingers. The mount also carries a 25-mm gun, and a 0.50-cal machine gun can be carried on the right launch beam.

Boeing's SWPS (Stabilized Weapon Platform System) concept. (Boeing)

◆ Other U.S. 20-mm Mounts

Although early U.S. 20-mm guns are capable of anti-aircraft fire, they are primarily surface weapons. These guns are now being replaced in that ASUW role by the 25-mm Bushmaster or Chain Gun (see the Strike/Surface Warfare section), which clearly is a surface weapon. Some single 20-mm guns of U.S. design also survive in foreign navies.

World War II mounts carried a Mk 4 (Oerlikon) gun, using an 80-rnd drum magazine. This gun had a cyclic rate of 450 rnds/min and a muzzle velocity of 2730 ft/sec. Effective range was 2000 yd (maximum range 4500 yd at 35-deg elevation). This gun was blow-back operated.

A single World War II-type 20-mm Oerlikon gun on board the Belgian minesweeper *Breydel*, 1985. (M. Loagie)

The newer 20-mm guns are Mk 16s, modified aircraft guns (Hispano-Suiza HS404, designated M3) that are slightly lighter (116 vs. 150 lb) and shorter (78 vs. 84 in), and that are fed by box magazines carrying disintegrating link belts. The ammunition and muzzle velocity are the same, but cyclic rate is 600–650 rnds/min (reduced from the 800 rnds/min of the aircraft gun). These guns are operated by a combination of gas and blow back. Mk 16 also has a special oiler to lubricate its ammunition. Mod 5 adds a hand-pulled stepped mechanical trigger. Mod 4 has an electrical trigger mechanism.

About 5000 Mk 16s were delivered during the Vietnam War, and Mk 16 is a standard coast guard weapon. In recent years many M24 (air force version of M3) aircraft cannon have been cannibalized for Mk 16 conversion.

The then Naval Ordnance Systems Command developed a series of alternative 20-mm guns in the late 1960s and early 1970s, but ultimately adopted the 25-mm Chain Gun instead.

In the list below, Mk 10 and Mk 24 were the World War II single and twin mounts. Mk 67 was the standard mount for the Mk 16 gun, introduced in 1971 on board the *Tarawa* (LHA 1). Mk 68 was a stop-gap until Mk 67 could enter production; Mk 68 was tested in 1970 on board a radar-picket ship.

Only Mk 67 and Mk 68 are in current U.S. service; earlier mounts survive abroad.

◆ 0.50-Caliber Machine Gun (M2)

This standard U.S. heavy machine gun is used on board many coastal craft. Total weight is about 87 lb, and total length is 65 in. The gun is recoil-operated, and it fires 450–550 rnds/min. Muzzle velocity is 2900 ft/sec (nominal), and effective range is 1500 yd. Maximum horizontal range is 7400 yd (35-deg elevation). A 100-rnd disintegrating-link belt weighs 30 lb. This gun is often combined with an 81-mm mortar in an over-and-under mount.

Many surface combatants and auxiliaries have pedestal

MOUNT CHARACTERISTICS

	Mk 10	Mk 24	Mk 67	Mk 68

mounts on which shielded 0.50-caliber machine guns can be placed, for defense against small boats and swimmers. Sometimes these weapons are mistaken for larger 20-mm cannon. Typically small ships carry 2, destroyers and cruisers carry 4, and larger ships carry 8 of these machine guns.

A new mounting, Mk 26 Mod 15 (soft recoil), was developed by NSWC Crane. It entered service during the Gulf crisis. Mod 15 was originally developed after the 0.50 began to appear aboard large ships in 1978. It was soon apparent that the hard recoil of the existing version of the Mk 26 mount drastically limited accuracy. Mod 15 was developed in the early 1980s, and limited production was approved about 1985. However, it did not become important until ships in the Gulf began to encounter small attack boats in numbers.

The 0.50 itself gained importance with the introduction of a new explosive round, developed by Raufoss in Norway. Previous attempts to develop such a round for so small a caliber had failed because the 0.50-caliber bullet was too small to admit a mechanical safing-and-arming device (which was required to ensure safety, e.g., if rounds were accidentally dropped). Raufoss developed, in effect, a chemical safing-and-arming mechanism. The hard body inside the bullet is surrounded by explosive, and a detonating charge is packed into a cavity in the nose of the bullet. When the bullet hits, the charge bursts and ignites the main explosive charge, while the solid penetrator passes through thin armor. However, if the bullet is merely dropped, the impact is insufficient to set off the detonating charge.

Raufoss describes the round as multipurpose (MP) because it combines armor penetration with explosive effect. This type of construction was originally applied to 20-mm rnds, and then to larger calibers up through 40-mm. The first 20-mm MP rnd was fired in 1968, and the first production batch was delivered to the Royal Norwegian Air Force in 1971. The 0.50-caliber rnd was a later development; as of the end of 1989, about 12 million will have been delivered. This round is in service with Norwegian, Danish, French, and British forces. It is produced under license by Olin, Pykal (British), and FN (Belgian). The round can penetrate 11 mm of armor at 950 m at a 30-deg angle. There are now 3 types: MP, MP/T (tracer, production of which began in 1988), and APS (which was first marketed early in 1989). The APS round can penetrate 20 mm of armor at up to 30 deg from the normal, at 400-m range. The MP round is credited with penetration of 25 mm of steel at a 45-deg angle.

Rounds originally bought by the U.S. Navy for evaluation were sent to the Persian Gulf in 1987 on an emergency basis. As of 1989, Raufoss is supplying these rounds to the U.S. Navy. The Olin Matheson Company in the United States obtained manufacturing rights to the basic technology in 1981. Rounds were ordered only in 1987, and as of 1989 the company was still experiencing difficulties in production. As of 1989, however, production of both 0.50-caliber and 20-mm rnds was underway in the United States, and 25-mm rnds were undergoing qualification tests.

Compared to conventional 0.50-caliber rnds, the Raufoss round is much more accurate because of its weight and the different location of its center of gravity.

The effect of the Raufoss development is to extend some of the advantages of the 20-mm cannon, until now the smallest that could fire an explosive shell, to the much lighter and more portable 0.50. Presumably, that in turn makes the 0.50 much more attractive as an anti-small boat weapon, to be carried aboard both small boats and helicopters. Large numbers of these rounds have been sold (more than 3 million in France, the best customer).

As of 1989, Raufoss was developing a new tracer round based on its technology. Olin has developed the Raufoss projectile into a new round, WALAP (Winchester Anti-Light Armor Projectile), due to enter production after 1989. It is optimized for air defense, sacrificing armor penetration for incendiary effect; even so it penetrates twice as well as 20-mm HEI and can even defeat some reactive armors. It uses a tubular tungsten penetrator. Olin also makes a sabot light-armored penetrator (SLAP),

containing a 7.62-mm tungsten penetrator in a plastic (Lexan) sabot. SLAP was developed for the U.S. Government Joint Service Small Arms Program (JSSAP) project, for better penetration against Soviet armored personnel carriers. Its trajectory is reportedly so flat that a special companion SLAP tracer is required. Its velocity is reportedly 1200 m/sec. Singapore Technologies also makes a SLAP round.

Reportedly, the current (1989) trend is to improve armor penetration. In the past, 0.50-caliber AP rnds were merely hardened steel bullets, with limited performance (20-mm RHA plate at 325 m). The most common current option is to use a tungsten core in an AP/Incendiary round (APHCI or APIHC). Here HC means hard core; tungsten alloy HC more than doubles penetration range.

◆ Gecal 50 Naval Gun

A British firm, Astra Holdings, displayed a naval version of the Gecal 50 0.50-caliber Gatling gun at RNEE 1989. This mounting could be operated by 1 person, and carried 750 rnds. Weight without ammunition is 268 kg, and working circle (radius) is 712 mm. Elevation limits are +70/-20 deg.

The GECAL 50 naval gun. (Astra Holdings)

A 0.50-caliber machine gun on board the *Mount Vernon* in the Persian Gulf, October 1987. There are supports for a splinter shield, which has not been fitted in this case. U.S. ships in the Gulf were also provided with M60 light (7.62-mm) machine guns. (U.S. Navy)

◆ 7.62-mm Mini-Gun

This miniature Vulcan weighs 60 lb, including the drive motor and de-linking feeder. Total length is 30 in. Muzzle velocity is 2800 ft/sec, and effective range is 1200 yd (maximum 4000 yd). Cyclic rate is 2000 or 4000 rnds/min, and a 1000-rnd belt weighs 64 lb.

The gun is designated Mk 25 in U.S. naval service and is the GAU-2B/A aircraft weapon adapted for surface use, mainly by Special Forces (SEALs).

◆ M60

Caliber: 7.62-mm/85 **Rate of Fire:** 500–650 rnds/min
Muzzle Velocity: 2800 ft/sec
Maximum Range: 4000 yd (effective 1200 yd)
Ammunition Capacity: 1000 rnds (belt) **Weight:** 24 lb empty

M60 has been the standard U.S. light machine gun since 1957. It is often mounted on board ships as a convenient defense against boarders and small craft, and it is used with the 60-mm mortar in an over-and-under mount. It was also a major riverine weapon during the Vietnam War and as such may survive in Southeast Asia. The standard (basic) infantry model weighs 23 lb. There are also helicopter/aircraft models (M60C and M60D). The basic version has the gas cylinder and bipod attached to the barrel, which has no handle, so the barrel is both expensive and difficult to change. In the M60E1 version the gas cylinder and bipod are attached directly to the gun, separate from the barrel, and there is a handle for barrel changing. M60E2 is a version for Marine Corps M60A1 tanks, adopted in 1977. As of 1985, all Marine Corps M60s (except those on board tanks) had been converted to the product-improved (M60E3) configuration, which had been standardized in 1983 (as of that year the Corps bought 4630 new guns plus 1650 conversion kits and 977 rebuilt guns). Recent purchases (navy funds, mainly for the marines): 1384 in FY86, 1807 in FY87, 257 in FY88. M60E3 is 25% lighter than the original basic M60.

The U.S. Navy also used a Mk 21 machine gun, an earlier 0.30-cal weapon (M1919A4) adapted to 7.62-mm ammunition, in Southeast Asia, but those retained in its inventory are for war reserve use only. A newer weapon, M240E1, a U.S. version of the Belgian FN light machine gun, has been adopted for Marine Corps light armored vehicles (LAVs), but thus far has not been used aboard ships. The British version of the same weapon (L7A2) is used on board British warships (see the U.K. section).

which had been canceled in 1978. However, the 155-mm was rejected. Although the army's existing special-purpose rounds had been proven on shore, many of them could not be used in the naval electromagnetic environment without extensive and costly modifications. The marines, therefore, had to be satisfied with a combination of the existing 5-in guns and the revived 16-in/50s of the battleships.

The FMC project remains interesting for its unique loading system. All other naval guns load either at a fixed angle near the horizontal or at a variable elevation angle. For the 155-mm, FMC proposed loading vertically, the gun forming, in effect, a continuation of the loading hoist. Projectile and charge were loaded onto separate horizontal trays in the magazine, and then each tray rotated to the vertical, so that shell and powder rose in the proper sequence toward the breech. Shell and powder were there rammed together. After firing, the gun elevated so that its breech was in line with the empty-case door, ejected the case, and then continued to elevate to the vertical. The main advantage was that the gun could fire projectiles of differing lengths; inserting long guided projectiles greatly slowed the rate of fire of the existing 5-in/54. The usual loading tray was eliminated completely from FMC's design.

In 1981 FMC estimated that the mount could be ready in 6 yr (3 for development, 3 for production), that it would weigh less than 50,000 lb (revolving weight 43,000 lb), and that it would be cheaper and more reliable than the 5-in/54 (MRBF about 1320 rnds). The gun would have been a 155-mm/50, and elevation limits would have been $+75/-10$ deg (training rate 30 deg/sec, elevation rate 50 deg/sec). The conventional 155-mm shell would have weighed 103 lb, the guided shell 225 lb, and FMC claimed that the sustained firing rate would have been 10 rnds/min.

FMC has also proposed vertical-loading 5-in/54 and 8-in/36 guns. The 5-in/54 would have achieved a sustained rate of fire of 10 rnds/min, either conventional or long round. Weight dry without ammunition was given as 29,990 lb including barrel, of which 5700 lb were below deck; this compared with 47,820 lb for the lightweight conventional Mk 45. Elevation limits were $+75/-10$ deg, and the train rate was 40 deg/sec (elevation rate 50 deg/sec).

The 8-in/36 would have sustained the same rate of fire. Total mount weight (dry without ammunition) would have been 60,200 lb, of which 8700 lb was off-mount. Elevation limits were $+75/-10$, and train rate was 30 deg/sec (elevation rate was 50 deg/sec). The shell weighed 200 lb (250 lb for a guided shell). Presumably, the 8-in gun would have fired army 8-in shells.

◆ Combustion-Augmented Plasma (CAP) Technology

This high-energy gun technology was announced by FMC in 1987. This type of gun is a hybrid between an electrothermal (ET) and a liquid-propellant (LP) cannon; about 20% of muzzle energy is derived from an electrically generated plasma, and 80% from a conventional chemical reaction, as in other liquid-propellant guns. Compared to a pure electromagnetic gun, the CAP gun requires about a third as much electrical generating power. Compared to other new-technology guns (such as rail guns), the main disadvantage of the system is its complexity. On the other hand, the CAP gun has the shortest barrel (for a given performance) of a series of weapons, including pure liquid propellant guns and advanced conventional guns.

In this type of weapon, a sudden discharge of electricity heats the propellant in the breech to 5000 deg C and causes an ion plasma to form. The oxidant is then added. The resulting combustion is more rapid than usual and adds about 25% to the muzzle velocity of the weapon. That increase in velocity approximately doubles the range of the gun and, at short ranges, greatly increases the energy of the shell. In addition, because time of flight is reduced, fire control may be simplified, e.g., in antimissile defense. In the 1987 announcement, FMC showed its version of CIWS 2000, which carried 2 rather than 6 barrels.

The first experiments used 10-mm projectiles, but later

An M60 machine gun on board the USS *O'Brien*, 1980. (U.S. Navy)

◆ 155-mm (6.1-in) Vertical-Loading Gun

This weapon was proposed by the FMC Corporation, the manufacturer of the U.S. 5-in/54 and 3-in/62, in 1981, to fire the army's existing standard rounds. The marines saw this weapon as a replacement for the 8-in/55 lightweight fire-support gun,

FMC's concepts for CAP (trademark) naval gun systems. (FMC)

30-mm were fired, and FMC expects to fire 90-mm projectiles. All of these experiments used liquid propellants, although a conventional solid propellant might also be used.

As of 1987, FMC was applying its CAP technology to an air force-funded hypervelocity ammunition technology (HAT) pro-

gram, in which a sideways-pointing antitank gun is to be mounted on board a C-130 or successor gunship that would fly just behind the battle line. CAP was also proposed as part of a hybrid rail gun for antimissile defense, to be used to inject a projectile into the electric gun.

FMC patented its CAP concept in 1985, and in 1990 it began a CAP naval gun project under the U.S. Navy's Balanced Technology Initiative. This weapon is also described as an electrothermal gun (ETG), and it is considered a much nearer-term proposition (e.g., for point defense) than a full electric gun. Compared to alternative exotic guns, CAP can use a conventional barrel and projectiles. FMC claims that CAP offers better reliability and internal ballistics control than a liquid-propellant gun.

FMC won a U.S. Army contract for a 120-mm electrochemical-gun demonstrator. The company has already demonstrated a 105-mm CAP gun with a muzzle velocity greater than 2500 m/sec. The army's 120-mm gun should be tested for the first time late in 1991.

For the army, the issue is kinetic energy since it is kinetic energy that penetrates tank armor. FMC offers 9 megajoules (MJ) at a muzzle velocity of 2500 m/sec, or 18 MJ at 1700 m/sec, or 4.5 MJ at 3000 m/sec. A conventional 120-mm tank gun produces 9 MJ at 1650 m/sec. FMC expects its CAP gun to be able to fire 3 rnds/min for 3 min, and to fire 100 rnds between major component changes. Firing rate and duration are presumably limited in part by the electric power stored at the gun, although they are not nearly so severely limited as in a pure electromagnetic weapon.

In contrast, a naval ETG would probably be optimized for high muzzle velocity, to simplify fire control against fast maneuvering targets. Reduced muzzle energy could be accepted as long as the projectile was heavy enough to be lethal against a fairly flimsy target. Moreover, the gun would benefit from the substantial electric energy output of the ship carrying it.

◆ Liquid-Propellant Gun Technology

For some time General Electric has been developing the technology for liquid-propellant guns for the U.S. DoD, both for ground and for naval missions. By 1983 GE had demonstrated its new regeneratively pumped direct-injection-combustion technique in a 105-mm test gun. Although not yet applied to a naval weapon, this technology is potentially important enough to be included here.

Interior ballistics are controlled by metering the propellant into the combustion chamber. Thus, to a considerable extent, a gun's muzzle velocity, hence range, can be varied without varying the elevation angle. Bulk stowage of propellant greatly reduces the weight and bulk of ammunition, and quicker loading of propellant can greatly increase the rate of fire. In the GE system, once the first round has been fired, the pressure in the combustion chamber is used to pump in the next load of propellant (hence the regenerative name).

YUGOSLAVIA

◆ 20/4 M75

Caliber: 20-mm **Rate of Fire:** 650–750 rnds/min
Muzzle Velocity: 850 m/sec [2790 ft/sec]
Training Rate: 80 deg/sec (elevation 50 deg/sec)
Elevation/Depression: +85/–10 deg
Ammunition Capacity: 4 × 60-rnd drums
Effective Range: 1500 m [1650 yd]
Working Circle: 1.895 m [radius] [74.6 in]
Weight: 1900 kg [loaded] [4190 lb]

Yugoslavia manufactures and uses this quadruple 20-mm gun. The guns themselves are locally made Oerlikons of World War II configuration, mounted 2 to a side, 1 above the other, with their ammunition drums protruding on each side. The rate of fire given is for the mount as a whole, not for the individual guns. Each gun can fire 180 rnds at a time but must then stop for 5–10 min to cool down.

The individual 20-mm gun is designated 20/1 M71. It is not

clear whether it is a World War II Oerikon or a locally made version of the current A41, which is somewhat different (photographs in the official Yugoslav arms catalog seem to show 2 versions). The single mount can elevate and train at 80 deg/sec (limits +90/-10 deg), and it weighs 460 kg [1014 lb] loaded.

The single mount is fitted with a reflex sight (RNS-M71T) with an FOV of $\pm 20 \times \pm 10.5$ deg; the objective lens is 110 $\times$ 120 mm, and total weight is 3.5 kg [7.7 lb].

SHIPBOARD ELECTRONIC WARFARE

This section includes 2 very different classes of systems: chaff or decoy launchers and electronic intercept/jamming devices. There are also a few towed or floating decoys and some electronic intelligence devices.

A chaff launcher can have 1 or more of 3 distinct functions. Firing at long range, the launcher can provide a targeting radar or an incoming missile with multiple targets. If all targets must be engaged, the attack is diluted, and close-in weapons have a better chance of dealing with those weapons that do lock onto the ship herself. The usual counter-countermeasure is MTI (moving-target indication). A radar easily distinguishes an airplane from chaff because the real target is moving so much faster. Such a distinction is much more difficult to make if the target is a ship. The second, intermediate-range function is to seduce the missile seeker away from the ship target onto a decoy cloud. The missile seeker is designed to avoid such seduction by using a range-gate, i.e., by reacting only to signals within a narrow band of ranges around the expected target's position. An active ECM transmitter (range-gate stealer or range-gate pull-off) is used to move the missile's seeker into the chaff cloud some distance from the ship. Finally, there is a last-ditch tactic, centroid seduction. The missile's seeker generally homes on the centroid of the target's return, seeing the ship target as a complex array of point and corner reflectors. If a large chaff cloud is added, it moves the centroid up and away from the ship target, and the missile may pass overhead or to the side. Success in this mode depends upon the reflective cross section of the chaff cloud compared to that of the ship proper. If the cloud is designed merely to move the centroid up, that countermeasure may be countered by a radio altimeter that keeps the incoming missile at low altitude.

Chaff (and IR decoys) may be launched by rocket or mortar. Rockets provide longer range (for the dilution role) and do not impose any load on the surrounding deck. However, they are relatively large, and a designer must protect against their back blast. Mortars are more compact, as is their ammunition. Both types exist in considerable variety.

ECM devices fall into 2 broad categories, intercept receivers (often termed ESM, electronic support measures) and active countermeasures (jammers and more sophisticated deception devices). ESM includes not only attack warning but also passive detection of air and surface forces beyond the sensor's horizon. Although such detectors may be considered more as antiship targeting devices than as self-protection, they are most conveniently included here. Attack warning requires, at most, coverage of the standard air-to-surface radar (X-) and missile-seeker (X- and K-) bands. OTH detectors of surface ships may exploit both the sea-wave emissions of P-band air-search radars and HF communications.

These devices can also be divided into wide-open and narrow-beam scanning types. A wide-open detector will pick up very short signals, but it may lack sensitivity in any 1 direction, and it will also generally lack directional precision. A narrow-band scanner will provide good directional data and may achieve great sensitivity; but with a finite scanning rate, a narrow-band scanner may miss a very short transmission. In the past, British practice has generally favored wide-open detectors using fixed antennas (and measuring signal direction by phase comparison); U.S. practice has favored rapidly scanning directional antennas (as in SLR-12). Current U.S. practice employs electronic scanning, in which a wide-open antenna can form numerous narrow beams continuously and simultaneously (e.g., SLQ-32).

Active countermeasures employ a variety of tactics, from simple noise (barrage) jamming up through false-target transmitters sequenced to confuse scanning radars. There are also multi-antenna antimonopulse techniques. For many years U.S. escorts were fitted with blip enhancers intended to make it difficult for an approaching antiship bomber to distinguish them from the accompanying carrier. Reportedly the implicit missile-absorber role was less than popular, but this measure suggests the subtlety of electronic warfare. Currently the U.S. and Royal Navies use floating decoys, which are called "rubber ducks" in analogy to hunters' decoys.

AUSTRALIA

◆ Winnin/Nulka

Winnin is a hovering rocket that carries an active jammer; the complete system is called Nulka. By hovering, the decoy prolongs its life. It can also be powered to move slowly away from the launching ship, thus simulating the movement of a real ship. The key technology is a variable-thrust solid-propellant rocket, whose thrust automatically decreases as the weight of the vehicle decreases (through fuel burning). Servo tabs in the rocket's exhaust control the rocket's direction. Winnin is fired in a precomputed direction but can also receive control data while in flight. This degree of control simplifies launching arrangements since the decoy can fly in the required direction whatever its initial launch path.

The hope is that the attacking missile will fly below the hovering decoy, on a heading away from its intended target. In that case it is, in theory, precluded from acquiring another target. The decoy, therefore, has its own sensors, which detect the character of the incoming missile and which also gather weather information. These data are passed back to the launching ship by data link, and a processor on the ship can feed back commands. The entire decoy system can be integrated with an automated CIC.

The decoy can be fired from a Mk 137 (SRBOC) launcher or from a 10-rnd module. The U.S. Navy calls the rocket "Hoveroc," and its tubes will be added to existing U.S. SRBOC tubes. In this form the rocket can carry an IR payload in addition to its active-radar decoy.

Winnin was conceived in 1974 and first flew in 1981. The concept was developed by the Weapons Systems Research Laboratory at Salisbury, South Australia, and by the Government Aircraft Factories in Melbourne. It has been tested by the Italian navy.

CANADA

◆ CANEWS (SLQ-501)

MEL's system for the Canadian "City" class was first tested in the fall of 1981. CANEWS embodies the MEL instantaneous-frequency-measurement (IFM) device also used in the British Abbey Hill system (see below) and claimed, in 1983, to be the only one of its type manufactured in Europe. Some accounts suggest that CANEWS is a derivative of the British UAA-1.

Radar intercepts are compared with a library, providing automatic classification within 2 sec of an intercept. The system covers 1-18 GHz in 5 bands, each with its own receiver (8 horns, wide open in frequency, for full 360-deg coverage, a bearing accuracy of better than 4 deg, and a frequency accuracy of 5 MHz). The system can be expanded below 1 GHz if desired. Two UYK-20 computers are used, to process up to 500,000 pps; the library stores up to 2000 emitter modes, tied to geographical area. The operator can add up to 128 emitters (a "regional" file, of radars most likely to be encountered). There is also a smaller preprogrammed threat library. CANEWS was described as fully automatic, unlike the British Abbey Hill.

The antenna weighs less than 200 kg. It consists of 8 boxes, each covering 45 deg and each carrying 4 radomes, for 4 frequency bands. The 2 highest-frequency radomes are side by side, with intermediate- and lower-frequency radomes below. Four

CANEWS antenna array. (MEL)

CANEWS, SLQ-501. (MEL Defense Systems)

Band-0 (low frequency) units are located between the pairs of 45-deg boxes. Each antenna feeds a wide-open receiver; in addition, there is an omnidirectional antenna feeding an IFM.

Work began in 1973, the MEL proposal being accepted in 1976; the first set was delivered in July 1980. It was tested on board the Canadian frigate *Terra Nova* that October. CANEWS was selected for the Destroyer Life Extension Program and then for the "City" class. Successful sea trials of a production set were reported in mid-1983. The first operational installation was on board the frigate HMCS *Huron*, in 1986; and by early 1987 CANEWS was also on board HMCS *Gatineau* and *Huron*, with 4 more installations planned. The new "City"-class frigates will carry communications intercept-and-DF equipment in addition to CANEWS, and also the MEL RAMSES (SLQ-503) noise/deception jammer.

MEL Defense Systems (of Canada) was set up specifically for this program.

◆ SLQ-503 (RAMSES)

This MEL system is combined with CANEWS (SLQ-501) in new and modernized Canadian destroyers. RAMSES is an acronym for Reprogrammable Advanced Multimode Shipboard Electronic-Countermeasures Systems. RAMSES can operate either under SLQ-501's control or independently. Software-controlled, RAMSES can jam several threats simultaneously. MEL claims

that RAMSES is effective against monopulse radars, even though it uses only 2 antenna assemblies, 1 to port and 1 to starboard. Each incorporates a pair of radomes, presumably for 2 different frequency ranges.

◆ Low-Cost MM-Wave ESM

In August 1990 MEL announced a new low-cost mm-wave ESM receiver, for which it had conducted systems engineering as well as proof-of-concept development. Because MEL is the EW systems house for the Canadian navy, its new ESM device will probably appear on board Canadian surface ships. The Ka-band receiver can be built in 4-, 6-, or 8-port versions, and it has digital output. It can handle pulse widths from 50 nanosec to CW, and the throughput rate of the associated ESM device, presumably with 8 ports like SLQ-501, is better than 500,000 pps. Bearing accuracy is 5–7 deg, and elevation coverage is 40 deg. Sensitivity is –60 dBm, and dynamic range is 60 dB.

◆ Model 100

This naval direction-finder, manufactured by General Precision Industries, covers 10 kHz to 180 MHz. For LF/HF Model 100 uses a pair of multiturn switched loops (sense from balanced dipoles); for VHF the system uses 16 monopole elements that can be arranged as crossed-Adcock and parallel-dipole arrays for both horizontal and vertical polarization. There is also a ground mobile version, Model 109. This system dates from the early 1970s.

Signals are displayed as bearing lines on a CRT. Bearing and frequency can be displayed together by using color modulation to indicate the latter.

◆ CCP/TECMUS

Canadian ULQ-6 ECM systems are currently being upgraded by addition of Telemus Electronic Systems' Coherent Countermeasures Processor (CCP). The initial improvement to the ULQ-6 was replacement of the original Frequency Memory Loop (FML) for better reliability; later Telemus replaced all major ECM components except the antennas and the high-power transmitter tubes.

ULQ-6 is a reactive (deception) jammer, and it uses the FML to shape the jamming pulses into delayed replicas of the original pulse, e.g., for range-gate stealing. The old analog FML is replaced by a digital RF memory (DRFM) unit. An FML is not coherent, is limited in storage time, and cannot be filtered to reject the signal emitted by the jammer itself. Without such filters, the jammer signal leaks in through sidelobes, and the system as a whole tends to lock into a feedback loop. A target radar escapes jamming by shifting frequency or PRF. A DRFM can be filtered by software, so it can continue to return signals reflecting the character of the original.

The DRFM samples incoming signals at a rate of 120 million per sec, representing their amplitude by 4 bits, with an instantaneous bandwidth of 10–550 MHz within an operating bandwidth of 2–18 GHz. Memory capacity is at least 340 microsec of signals. TECMUS offers 4- or 8-channel receivers, or a combination. The 4-channel receiver uses a frequency divider to double the bandwidth of the DRFM, to keep a frequency-agile threat radar within a single channel. In either case a frequency selector detects and selects the proper channel within 25 nanosec of signal detection. Throughput delay from the receiver flange input to the transmitter flange is 10 nanosec, to capture leading (pulse)-edge trackers and narrow pulses. The DRFM contains 11 parallel processing channels (per signal channel).

Channelization makes for sensitivity; Telemus claims –70 dBm, sufficient to detect the sidelobes and backlobes of most search and target-acquisition radars. Frequency coverage is typically 7–11 or 6–18 GHz (customer specified), and each channel is 1 GHz or 500 MHz wide. The system can deal with pulse widths between 20 nanosec and 340 microsec, and range-gate delay resolution is only 8.5 nanosec. The associated library contains 100 spot entries.

Given the flexibility and sensitivity of the DRFM, the system

could do much more than merely return a slightly delayed replica of the incoming signal. The memory cycle is much faster than in the earlier analog processor. The full upgrade, therefore, includes a programmable countermeasures generator. It is called TECMUS (Tactical Electronic Countermeasure Upgrade System).

CCP/TECMUS includes an integrated, programmable, deception-techniques generator. ECM techniques include scan-rate modulation (SRM) (angle deception against conically scanned or scanned radars), swept SRM, false targets, and range-gate pull-off (RGPO) and pull-in (RGPI). Swept SRM is used against radars that scan on receive only, in the expectation that as the SRM modulation rate is swept, it will pass through their modulation rate. Other techniques, including noise, are available as options. Up to 4 RGPO programs can be run simultaneously and independently; SRM and swept SRM can also be run simultaneously with RGPO or RGPI, to maximize the chance of capturing the threat range gate.

False targets are injected into the sidelobes or backlobes of radars, as well as into the main lobes. The memory cycle is so short (8 nanosec, comparable with minimum-range bin size) that it should be possible to attack synthetic-aperture and other imaging radars. Similarly, because the memory cycle is very short, TECMUS can attack the elements of a chirped signal and, thus, can deal with pulse-compression radars (both phase- and frequency-coded).

Telemus argues that by running 4 RGPO programs simultaneously, it has an excellent chance of defeating a generic threat (i.e., a threat whose parameters are unknown). All of the RGPO programs include velocity profiles (each is a 3-segment velocity profile). The profile is user-defined, and it can terminate in zero velocity. The threat radar will quite possibly derive a velocity from target position, projecting ahead target position. If the RGPO ends with zero apparent velocity, the threat radar will be easier to shift onto a chaff decoy, as the threat system tracker will not be accelerating through the desired dump position. Telemus argues that this is the only way to defeat a monopulse angle tracker, which will then angle-follow the decoy away from the ship.

The operator inserts the desired offset angle in degrees into the system, and the system tells whether jamming on that bearing is possible. TECMUS does not emit until it has received a trigger signal from the threat radar; the jamming signal bears a constant relationship to that trigger, so that the apparent target is stable in range, even if the threat radar jitters or staggers its PRF. This technique in turn is possible only because the receiver reacts quickly enough to the trigger, rather than to a memory loop based on some earlier received signal.

TECMUS is run by two 68000-series microprocessors on a VME bus. One manages the system and the technique generators and is also responsible for power management of the TWT, within its available duty cycle (the operator is told if he or she is trying to execute too many programs in parallel). The other is the scan processor, reporting a lock-on or a conical scan or search-and-acquisition radar.

Telemus offers optional narrow-band receiver extension to deal with phase-coded as well as frequency-coherent (pulse-compressed) threats, and new antennas and high-power amplifiers.

The Telemus company also offers a system to improve the signal de-interleaving capacity of current broad-band ESM systems, and the company has received a study contract for a low-cost off-board active decoy.

CHINA (PRC)

At the ASIANDEx exhibition in Beijing in the fall of 1988, the China Shipbuilding Trading Co. displayed a radar noise jammer (EAJ-7), a decoy launcher (ERC-1), and a tactical data system (ECIC-1). No details of these devices are available.

The China National Electronics Import and Export Corp. offers a submarine radar ESM device, Type 921-A. It provides bearing accuracy within about 30 deg for signals at 2–18 GHz in 4

bands. There is no IFM. The antenna unit is a dome, 560 mm [22 in] in diameter and 515 mm [20 in] high, weighing 80 kg. The 4-band operation and lack of Western-style displays suggests that this system may be derived from Soviet ESM technology (as in Watch Dog) obtained prior to the Sino-Soviet split of the late 1950s.

The same company offers a surface-ship radar-warning receiver, RW-23-1, operating over the same 4 bands, and storing parameters of up to 15 radars. The system employs 2 antennas, 1 on either side of the ship.

BM/HZ 8610 is an ESM system advertised by the Southwest China Research Institute of Electronic Equipment. It covers the 2–8- and 7.5–18-GHz bands, with elevation coverage between +30/–10 deg. Frequency is measured to within 5 MHz, and direction to within 2.5 deg; sensitivity is better than –70 dBm (dynamic range 40 dB). Pulse width is 0.1–99.9 microsec, and the system can store 500–1000 radar modes. Data are presented both graphically and in tabular form.

FRANCE

ELECTRONIC SYSTEMS

◆ ARBB 32

Électronique Serge Dassault conducted the first design studies for this shipboard jammer in 1967, and ARBB 32B entered production in 1974. Two prototypes (ARBB 32A) and 10 ARBB 32B were manufactured in 1974–79, and they were installed on board the major French warships: the cruiser *Colbert*, the *Suffren*, the *Aconit*, the *Tourville*, and the first 3 ASW C70-class corvettes. ARBB 32 was limited to range-gate pull-off, and in 1979 the French navy asked ESD to develop a more sophisticated jammer, which became ARBB 33.

A few ships have the older ARBB 31.

◆ ARBB 33

Électronique Serge Dassault began design studies for this electronically steered multiple-threat shipborne jammer in 1979; the prototype was completed in 1983, and series production began in 1986. In current form, the system employs a pair of semicylindrical radomes (height 2.2 m, diameter 1.2 m, weight less than 500 kg), port and starboard, each of which contains upper and lower dielectric windows, containing the transmitting and receiving antennas, respectively. The antennas are electronically scanned, and there are thirty-six 10-deg lobes on each side (so that the direction of jamming can be controlled to within 5 deg). Jamming power is 100+ kW.

A major advantage claimed for ARBB 33 is its ability to counter target-designation radars as well as fire-control and missile-seeker radars. System functions are threat detection/classification; data transmission to a combat system; and jamming, either automatically after detection, or controlled by the EW system. Typically, jamming is coordinated with decoy firing.

The detector operates over H-, I-, and J-bands, measuring frequency, pulse width, PRF, and direction (accuracy within 5 deg); reaction time is less than 500 msec. The jammer operates over the same bands and can deal simultaneously with 2 (optionally 4) threats. Its primary operating modes are continuous noise, pulsed noise, synchronous false echoes, asynchronous false echoes, and range-gate pull-off (e.g., onto chaff). The jammer uses dish antennas for higher gain compared to the planar antennas of ARBB 32 and other systems. The bands are chosen to cover missile seekers, fire-control radars, and target-designation radars.

◆ ARBR 10

This ESM set has been replaced on board most French warships by ARBR 16 or ARBR 17. ARBR 10C survives on board the destroyers *La Galissonnière* and *Du Chayla*. ARBR 10F survives on board the cruiser *Colbert*. The antenna array, carried on a platform just below the masthead, consists of an omni antenna

ARBB 31 occupies the squat cylindrical radome on board the destroyer *Suffren* (ARBB 32 is on the foremast). The radome above is for ARBR 10F. (Sea Power)

ARBB 33 on board the French destroyer *Cassard*. Note the shield to prevent interference with the nearby satellite antenna above. (Sea Power)

and 4 directional antennas, with preamplifiers. Typically, ARBR 10 was combined with other equipment. For example, the *Tourville*-class frigates also carried a trio of U.S.-type spinning DF antennas and a German Telefunken Telegon TV masthead HF/DF.

◆ ARBR 15

V/UHF receiver.

◆ ARBR 16/DR 2000

The current standard surface-ship ESM system is made by Thomson-CSF. ARBR 16 works either with an ARBB 31 or 32 jammer (*Jeanne d'Arc*, *Colbert*, *Suffren* class, the F67-class frigates, the *Aconit*, and the first 3 C70 ASW class) and Syllex medium-range chaff; or with DAGAIE chaff launchers (8 *Commandant Rivière* class and the A69 class).

ARBR 16 is a modified DR 2000.

DR 2000 is an F-band analysis receiver for warning, for surface ships (2000S, with 27-kg antenna), and for submarines (2000U, with 34-kg antenna and, as an option, a 14-kg periscope antenna). DR 2000 is designed to detect pulse and CW signals, including those of frequency-agile radars, and it has a 500- or 1000-signal library against which the video signal (or an optional printout) can be compared. An automatic alarm is provided, either to begin jamming or to dive the submarine. Data output: band, PRF, pulse width, power level, antenna rotation period, jitter, and bearing. PRF accuracy is 1 Hz in 1000 Hz. Larger ships (ARBR 16) have a superhet receiver for greater accuracy in frequency.

There are 6 D/F antennas plus an omnidirectional antenna, and a frequency-determining unit (indicating whether a signal is in S-, C-, X-, or Ku-band). In DR 2000, these antennas are enclosed in a radome. This is the radome atop the masts of German S143B- and S148-class fast patrol boats (S143A has the newer FL1800 system).

DR 2000 is typically combined with Dalia 500 (500 threat modes) or Dalia 1000 (1000 threat modes). DR 2000 is to be replaced by DR 4000.

DR 2000 was introduced in 1977, and by 1978 a total of 136 sets were on order, including both the DR 2000S surface-ship version and the DR 2000U submarine system. Later sales included sets for small and medium maritime-patrol aircraft. By May 1980 orders totaled 165, and by 1988 the number in service or on order had increased to more than 400. The DR 2000U

submarine version is reported operational in 25 navies (presumably, it replaces the earlier DR 875, which was on board older Type 209 submarines, such as those in the Turkish navy). DR 2000U was the standard ESM set of German-built submarines, and it is the French navy's ARUR/ARUD.

Users of the DR 2000 surface-ship version are Argentina (A69-type corvettes), Belgium (*Wielingen*-class frigates), Ecuador (3 *Quito* and 3 *Manta* class), Greece (10 *Combattante-III* class plus 4 *Combattante-II*s), Germany (20 Type 148, 10 Type 343 minesweepers, 12 Type 331 minehunters), Indonesia (4 PB57 class), Iran (12 *Combattante-II* class, 2 now lost), Libya (10 *Combattante-II*, 1 now lost), Malaysia (4 *Combattante-IIAL* class), Peru (6 PR72-560 class), Qatar (3 *Combattante-III*), Turkey (probably 8 *Kartal*-class missile/torpedo boats), Tunisia (3 *Combattante-IIIs*), and Venezuela (6 *Constitucion* class, removed when Harpoon replaced Otomat).

The French navy's ARBR 16 installations are 2 *Clemenceau*-class carriers, the *Jeanne d'Arc*, 7 *Georges Leygues* class, 3 *Tourville* class, the *Aconit*, 2 *Suffren* class, 3 older destroyers (of 12 in existence in 1977), 17 A69 class, and 9 *Cdt. Rivière* class (now being transferred to Uruguay).

Probable submarine installations are Argentina (5 TR 1700s and 2 Type 209s), Australia (6 *Oberons*, replaced by the Timnex system), Canada (3 *Oberons*, now replaced by *Manta*), Brazil (3 *Oberons*), Chile (4 IKL Type 1300s and probably 2 *Oberons*), China (some purchased mid-1980s, possibly for SSBNs), Colombia (2 Type 209s), Denmark (2 *Narhvalens* [modified Type 206s] and 4 *Delfinens*), Ecuador (2 Type 209s), France (6 SSBNs, 4 *Rubis*, 4 *Agostas*, 8 *Daphnes*), Germany (18 Type 206s, 6 Type 205s), Greece (8 Type 209s), India (4 Type 1500s), Indonesia (2 Type 209s), Netherlands (4 *Dolfijn* class), Norway (10 Type 207s), Pakistan (2 *Agostas*, 4 *Daphnes*), Peru (6 Type 209s), Portugal (3 *Daphnes*), South Africa (3 *Daphnes*), Spain (4 *Agostas*, 4 *Daphnes*), Sweden (5 *Sjoormen* class, possibly 4 *Drakens*), Turkey (6 Type 209s), Venezuela (2 Type 209s), and Yugoslavia (possibly 2 *Sava* class).

The aircraft version is in the Atlantic (in French and Pakistani service, 40 aircraft), Gardien (5 French naval aircraft), Super Frelon helicopters (24 built for the French navy for patrol out of Brest in support of SSBNs), and Super Puma naval helicopters (8 for Abu Dhabi, 6 for Brazil, 26 for Indonesia, 6 for Kuwait, 2 for Oman, 6 for Saudi Arabia, and 6 for Singapore). It is not certain how many of the helicopters were fitted with DR 2000H. Although DR 2000H was adapted for the EMB 111 and the Fokker Maritime Defender, aircraft of those types generally carry Elettronica's ESM equipment.

A new DR 2000U Mk 2 reduces size and increases performance. It covers the D-J-bands, and DF accuracy is about 6 deg. Total weight is about 90 kg.

Thomson-CSF is currently updating DR 2000 with a higher-sensitivity antenna and with an improved processor.

◆ ARBR 17/DR 4000

Thomson-CSF's ESM system (covering D-J-bands) for surface ships was announced in 1984 for the new generation of French warships, including the nuclear aircraft carrier *Charles de Gaulle* and the *Cassard*-class air-defense frigate. In these ships ARBR 17 cues the ARBB 33 jammer and the chaff launchers. In the new FL25 frigate, announced in 1984, ARBR 17 was intended to cue the 2 Dagaie chaff launchers. There are 2 antennas, an omnidirectional unit (initial detection, IFM, and threat analysis), and two 8-port directional arrays slightly below on the same mast (for D/F and more accurate frequency analysis).

The first ARBR 17 was installed on board the missile frigate *Cassard* in 1986.

DR 4000 is the export version. Compared with DR 2000, DR 4000 gives wider frequency coverage (C- through J-bands). There are 3 basic versions: 4000S for ships, 4000U for submarines, and 4000A for aircraft. The antenna array consists of 1 omnidirectional antenna and 2 groups of 6 directional antennas (1 each for the high and low bands, respectively H-J and C-G). Analysis involves 10 radar parameters, to reduce the chance of

mistaken identity. The system triggers an alarm if it detects a preset threat radar, such as a missile seeker, requiring instant attention. DR 4000 can process 15 tracks automatically and can track 40 emitters under operator control.

The display shows both raw video and a generated picture, using the usual NTDS symbols supplemented by 3-color coding to indicate particularly urgent threats (red is most urgent), on the theory that color should be used only to trigger an immediate response from an operator. Also showing jammer and decoy use, the display can be used for overall EW management.

DR 4000U has been adopted for the new Brazilian Type 209 submarines. Claimed DF accuracy is 5–6 deg, the antenna array consisting of an omnidirectional antenna (for IFM) and two 6-port assemblies, 1 for C–G-bands and 1 for H–J-bands.

The DR 4000 antenna consists of an omni and 2 stacked DF channels, each with 6 antennas. The omni antenna is 260 mm in diameter and 415 mm high (including a short knob at its top); it weighs 9 kg. The DF antenna fits within a 480-mm circle, is 425 mm high (including both frequency components), and weighs 44 kg (two 22-kg components). All components can be mounted together, or the DF antenna can be split into port and starboard segments. The below-decks console carries a display, a keyboard, and a trackball; the console also carries controls for chaff launching and for a jammer. It carries a de-interleaving module and a video processor. The screen shows 3 different displays: an "activity display" showing the tactical situation (with SENIT/NTDS symbols), a track display, and maintenance displays.

In the submarine version, DR 4000U, the 12 DF antennas surround the omni antenna (which is limited to a knob on top of the cylindrical radome).

Thomson-CSF designates DR 4000 as TMV 201.

Current users are Brazil (DR 4000U in Type 1400 submarines) and Saudi Arabia (*Al Madinah*-class frigates).

◆ Alligator

Alligator is Thomson-CSF's dual-mode (noise/deception) X-band jammer. Its antenna weighs 120 kg; its transceiver, 320 kg. Alligator was designed to work with the DR 2000 crystal-video ESM set. It incorporates an IFM to measure the frequency of the radar to be jammed; Thomson claimed that it could begin to jam upon receiving a single pulse. Alligator is a noise rather than a repeater jammer, the intent being to blind the targeting or surveillance radar rather than to confuse an antiship missile. However, its signal can be modulated in a preset (not reactive) pattern to confuse a missile (hence the reference to deception). Alligator 5A, the jammer for surface craft, was introduced early in 1978, and by later that year 15 were on order. That included 12 for Iranian *Combattante-II*-class missile boats (2 subsequently lost).

◆ ALTESSE

Thomson's shipboard communications alert and situation monitoring system was first displayed at Bourget Naval 1990 (October 1990), where it was described as the shipboard sensor providing the earliest warning. French naval trials were underway in the fall of 1990. ALTESSE is a potential successor to the German-supplied Telegon series of HF/DF systems. ALTESSE is built around the company's TRC 610 radio direction finder designed to overcome modern HF counterdetection techniques (frequency hopping, free-channel search, and burst transmission). ALTESSE integrates interception, DF, and analysis functions with short processing time; it also applies broad-base interferometry techniques for greater DF accuracy.

Operating modes are automatic scan (display is a frequency-bearing plot), recurrent surveillance mode (frequency-bearing plot of preset targets, with technical analysis data), and fixed-frequency (directional data displayed in polar or PPI format, with essential technical data). For example, the frequency-scanning (automatic-scanning) display shows minimum and maximum frequency of signals at an indicated bearing, frequency step (for a frequency-hopping system), measurement resolution

and duration, signal azimuth, center frequency, frequency range, signal level and duration, number of signals received (and measured), and a measure of signal quality. The display is a standard rectangular color CRT.

The base system operates over 20–500 MHz, using 2 nested arrays, each of 5 vertical dipoles, plus a sense antenna in the middle. The struts supporting the dipoles lie in the same plane. To extend coverage up to 1350 MHz, a third set of 5 shorter dipoles is added above the other 2. To extend coverage down to 1 MHz (1–30 MHz), the system adds a conventional pair of crossed loops. Bearing accuracy is better than 0.5 deg. There are separate HF (TRC 6113) and V/UHF (TRC 6123) antenna switches, both feeding a bank of 5 receive channels and a TRC 6105 signal processor. The signal processor in turn can supply data directly to a ship's combat system or to the TRC 6108 operator terminal.

◆ Dalia

Thomson-CSF's radar analyzer works with the DR 2000 receiver, operates over the E-J-bands, and uses IFM. Signals are compared to those in a 500–1000 signal library (the suffix, 500 or 1000, indicates the size of the library; Dalia 1000 was an-

nounced in 1976). Identification is based on the characteristics of 3 consecutive pulses, and as of 1976 Thomson-CSF claimed that any pulse train could be identified within 1.5 sec. When a signal matches several in the library, all are displayed, each with a "confidence level." Thomson-CSF designates the Dalia/DR 2000 system THV 433 or TMV 434.

◆ DBI 3000

Thomson-CSF's project for a new jammer integrates DR 3000 with the Janet jammer; BI presumably stands for *Brouilleur Integrale*. There may also be a phased-array jammer element to deal with shorter-range threats with high angular rates. DBI 3000 competes with Salamandre for future export orders.

◆ DR 3000

This system is under development (1988) and should be available in 1990–91. About half the weight of DR 2000U, DR 3000 covers the D–K-bands, with an accuracy much better than 6 deg. The antenna is the new lightweight type introduced in DR 2000U Mk 2.

There are 3 variants: DR 3000A (maritime aircraft), DR 3000S (surface ships), and DR 3000U (submarines). This system has been sold to the French navy, but the application has not yet been revealed and, therefore, the designation has not yet been released. It has also been exported. The surface-ship and submarine versions use masthead antennas with omnidirectional

DR 3000S components. (Thomson-CSF)

Size and weight

DR 3000U components. (Thomson-CSF)

elements above a series of monopulse directional antennas. The submarine version also has a separate periscope warning antenna. The maritime-patrol version uses 6 DF antennas plus an IFM antenna. All share a common processing unit (35 kg) and a common desktop console (42 kg) using a keyboard and a trackball. No specific data have appeared.

Compared to DR 4000, DR 3000 uses new technology to achieve higher sensitivity (with a low-noise amplifier in its antenna) and better instantaneous DF accuracy (better than 1 deg monopulse accuracy for targeting, with better accuracy available as an option). The proprietary IFM is fast enough to measure frequency within a pulse or on a subpulse basis, accurate to within a few MHz. An ASIC-based window processor is used to compare received pulses with those already identified and tracked; up to 256 series of pulses can be handled in this way. The use of the comparator reduces system identification workload and, thus, makes it easier for the system to acquire new signals rapidly while operating in a very dense pulse en-

vironment (over a million pulses/sec). An expert system approach is used for pulse identification.

◆ DR 3012 (Arial)

This broad-band omnidirectional radar receiver for surface ships and submarines is made by Thomson-CSF. DR 3012 normally operates with an Arial 15 analyzer, intended for small ships operating briefly in low-threat environments. The system's memory is manually programmed with about 15 radar modes.

◆ ELISA

The latest Thomson-CSF ESM/ELINT system can also work with DR 4000. ELISA is an acronym for ELINT, Search and Analysis. ELISA covers the C-J-bands (500-MHz instantaneous bandwidth) and is considered sensitive enough to detect a radar's sidelobes or diffused lobes. Signals may be designated to this system by a DR 4000 operator; ELISA carries out detailed analysis using superheterodyne techniques. Search parameters, including those of friendly radars (which are to be locked out), can be programmed in. The plasma display shows a series of histograms (DF, amplitude for scan rate, pulse width, and PRI); the operator positions markers in each histogram to read out

the measured radar parameters, which are displayed below the 4 histograms.

♦ Janet

Thomson-CSF's shipboard I/J-band jammer is usually associated with DR 4000. Janet provides both noise and deception jamming, either in sequence or simultaneously. Each jammer is computer-controlled for automatic response and for choice of tactics; the computer can store received signals to recreate them for deception jamming. A full Janet is built up of up to 4 modules, each incorporating an IFM receiver and a 2-horn antenna for signal acquisition and for monopulse signal tracking (azimuth and frequency, not elevation).

Each module contains 2 TWTs, 1 for noise and 1 for deception jamming. Thus it can jam 2 threats (from different directions) simultaneously. The associated receiver provides accurate bearing and frequency measurement after the system has been alerted by an RWR. Reception is sufficiently insulated from jamming transmissions so that the system can receive the signals it is attacking while jamming; there is no look-through pause in the jamming. Thus, Janet can deal with frequency-agile radars, which can defeat the usual jam/see-through systems.

Jamming modes include noise, pulsed noise, self-masking, various forms of deception, and blip-enhancement.

Each module is 1000 mm (diameter) × 270 mm and weighs 250 kg.

Janet is part of the electronics suite of the Saudi *Al Madinah*-class frigates. The first Janet was delivered in 1985.

Thomson-CSF is working on an upgraded Janet, on the theory that it would be more affordable than ARBB 32 or SLQ-32; the

Janet. (Thomson-CSF)

company feels that it may yet be adopted for the new frigates. Its argument is a combination of relatively low cost and high ERP (compared to any phased array). The company also argues that because the basic Janet already exists an upgrade will be relatively quick and inexpensive.

♦ NEWSY/NADS

NEWSY, the Naval Electronic Warfare System, is intended for the C70AA class and the carrier *Charles de Gaulle*. NEWSY uses a dedicated computer that monitors an ARBB 17 ESM system (D-J-bands) and operates an ARBB 33 jammer and chaff/IR decoy launchers (DAGAIE and SAGAIE).

NADS is the export version of NEWSY.

♦ Salamandre

Dassault Electronique's series of modular integrated EW systems is based on its experience with systems such as ARBB 33. Salamandre consists of a receiver (a pair of half-pie-shaped radomes clamped around the ship's masthead), up to 3 phased-array transmitters in cylindrical radomes (generally arranged around a ship's mast), and separate processors and control/display consoles. There are 4 versions: (V)1 is ESM only, (V)2 provides 1 jammer canister (providing 360-deg coverage by a combination of electronic and mechanical steering), (V)3 provides 3 canisters (instantaneous 360-deg coverage), and (V)B is a jammer only. (V)1 and (V)2 are suitable for ships of under 1500 tons; (V)2 is considered insufficient for a ship displacing 3000 tons or more. Total weight of the (V)3 version is 800 kg.

The ESM subsystem uses wide-band phase interferometry for precise (within 1-deg RMS) direction finding and threat tracking in the E- through J-bands (C- and D-bands are available as options). Sensitivity is better than 55 dBm. The manufacturer claims that its form of interferometry is inherently much more precise than the more usual reliance on amplitude comparison. It argues that azimuth is the only stable parameter of a modern threat (particularly a missile homing on a ship); radar parameters are easy to vary from pulse to pulse. The company also argues that, the better the direction-finding accuracy, the easier it is to deinterleave pulse trains and thus to identify an incoming signal. Signal frequency, pulse width, and pulse repetition interval are measured and compared with a library of more than 2000 radar modes. Salamandre uses an array of TWTs for jamming. Because it has multiple jamming transmitters, it can achieve high radiated power against 1 target (by combining several transmitters), but it can also switch rapidly in azimuth and in frequency, and it can overcome the failure of any single TWT.

Salamandre can handle up to 8 threats (depending on scenario) in the H-J-band, reacting in less than 5 sec. The main jamming modes are continuous and pulsed noise, cover-pulse jamming

Janet jammer on the foremast of a Saudi *Al Madinah*-class frigate (the 2 round radomes on the left, one above the other). The wire arrays near the masthead are for a Telegon VI HF/DF. The collars below them are a pair of standard French navy mast UFH antennas (AN 192). The big rounded radomes conceal Otomat control antennas. The radar visible is Sea Tiger. The DAGAIE decoy launcher (without its "suitcases") is on the platform below the top of the superstructure. (Thomson-CSF)

(masking), synchronous and asynchronous false echoes, range-gate pull-off, and dual mode.

Salamandre is to be installed on board the new *La Fayette*-class frigates.

◆ SAPIENS

SAPIENS is Thomson-CSF/CSEE's surveillance alarm and protection, intelligence EW naval system. There are 3 versions. SAPIENS 1, for small craft, uses Dalia and a 1000-emitter library, DR 2000 receiver, and DAGAIE launcher. SAPIENS 2 uses DR 4000S with IFM and can detect low-frequency radars. SAPIENS 3 has a noise and deception jammer.

◆ Shiploc

Shiploc is a small-ship version of the Thomson-CSF Sherlock (TMV 011) airborne radar detector. Reported resolution: 22 deg, 130 dB. Typical displays are LED (to show up to 4 threats) and a small-diameter synthetic-video CRT (marked out in 30-deg sectors). The LED display shows threat bearing, approximate course, and priority; it assigns a letter or number to indicate the type of threat. Shiploc competes with the British Matilda. No sales have been reported to date, but the system is still being marketed.

◆ TMV 026

TMV 026 is for fast patrol boats, to interface with the Vega FCS as well as with Signaal's FCS. Connected with the DR 2000 and Dalia 500, TMV 026 provides coverage of the E-G-bands.

◆ TMV 430

This ESM suite was designed for fast patrol boats but is adaptable to submarines and to larger surface ships. It comprises a DR 2000 broad-band receiver, an analysis/identification/warning receiver such as the Thomson-CSF's Dalia 500 or DR 3012, a noise/deception jammer (such as Alligator 5), and a printer.

◆ TRC 243/298

Thomson-CSF offers naval COMINT workstations using the company's standard land-based modules (TRC 243 for HF, TRC 298 for VHF/UHF). TRC 298 uses an ultra-fast frequency synthesizer, controlled by 2 processors. It can handle 1-100 frequencies and scans 1-10 sub-bands, masking known frequencies to contain its workload.

EXPENDABLES

◆ DAGAIE

This short-range decoy system stands alone on small warships and complements SAGAIE on board French destroyers and larger ships. DAGAIE is sometimes marketed as Squid. The trainable launcher carries 10 suitcase-type charges, each 24 × 31 × 5 in (up to 110 lb). In small ships, 1 launcher is mounted on the centerline; larger ships have 2 launchers. Each suitcase in turn contains either IR or radar decoys fired by mortar, the IR decoys reaching various altitudes and then descending in sequence by parachute to prolong their individual and net effect. Given a warning signal, calculation time is less than 0.2 sec, and each launcher slews at 1.2 rad/sec.

The manufacturer, CSEE, credits the system with the capability to deal with up to 5 incoming missiles in less than 10 sec (i.e., 1 IR and 1 radar suitcase per missile). A suitcase contains 33 predirected mortars (34 for IR). For IR, there are 10 initial-action and 24 continued-action charges. The initial-action charges operate very close to the ship and break up IR tracking. The delayed-action charges extend the net operating life of the decoy and ensure that the chaff cloud is colocated with an IR source. Alternative suitcases "A" and "B" can be used to deploy clouds at different altitudes, maximum altitudes being 150 and 300 ft, respectively. Combining both types gives a very large cloud, with a radar cross section of up to 24,000 yd². A special suitcase (Type D) provides a smaller cloud (3600 yd²) for small vessels.

DAGAIE launcher. (Compagnie de Signaux et d'Entreprises Électriques)

The radar decoy's bloom time is less than 2 sec, 132 blooming points being distributed per suitcase, to form a radar reflector over 5500 yd² in area, covering H- through J-bands and lasting longer than 10 min. The IR decoy's duration is 30 sec, the emitting surface having an area of 360 yd² at an altitude of 45 ft. Individual decoys hit the water at 1-sec intervals, after having drifted with the wind.

There is also a 6-suitcase version (990 lb rather than 1100 lb for the 10-suitcase launcher).

The system provides recommended helm orders for evasion based on the expected decoy disposition.

In large warships (frigates and above), DAGAIE is generally used in conjunction with SAGAIE, providing close-range back-up. DAGAIE was developed to meet a 1974 French navy requirement for antimissile self-defense for ships; DAGAIE had to be able to cope with attacks distributed around the horizon and had to be quick acting (reaction time about 5 sec).

The large-ship DAGAIE launcher is designated AMBL-1B.

The DAGAIE "suitcase."

A new version, DAGAIE Mk 2, was announced in 1986. It has a more powerful computer and digital/analog, rather than pure analog, interfaces. Mk 2 can, therefore, be integrated with a computer-based combat information system such as SENIT or NTDS. Mk 2 is also designed to fire new chaff and IR rounds requiring more complicated software, such as dilution decoys. A new medium-range REM rocket can be carried in a standard-sized suitcase (4 per suitcase), fired individually. Each round has a radar cross section of about 1000 m² and deploys 800 m from the launcher. The basic DAGAIE launcher can still carry the earlier types of suitcase; the new rounds replace 1, 2, or 3 modules in the middle of the mount.

◆ LAD

Leurre Actif Decale, or launched active decoy, was the subject of a 1986 competition between Thomson-CSF and ESD. LAD is to be fired from both DAGAIE and SAGAIE launchers, and maximum dimensions are 127 mm × 1.76 m (weight 27 kg). LAD will be launched and deployed in 8 sec and should operate for 60 sec. The dimensions make it compatible with the U.S. Mk 36 SRBOC launcher. In 1988 LAD was described as a centroid decoy, carrying a mini-TWT wide-band transmitter (10 kW, 40-sec operation). ESD reportedly prefers deception (presumably by means of a repeater); Thomson-CSF, a noise jammer (which is simpler to implement and may overcome pulse coding). As of 1988, there was no official program, and LAD was being referred to as RAD (Remote Active Decoy). Each round was likely to be both complex and expensive, and there was some interest in an RPV-carried (reusable) solution.

◆ MAGAIE

A lighter version of SAGAIE, MAGAIE carries only 3 suitcases. There is only 1 type of ammunition (chaff/IR combined); as in DAGAIE, the mortars are trainable but are fixed in elevation. Operation is fully automatic, based on an attack alarm from an ESM detector, a search radar, or an optical director. The threat sensor provides bearing, and the ship also provides relative wind direction and velocity and ship's heading and speed. Once the decoys have been fired, the system provides recommended helm orders for evasion (favorable course, emergency maneuver, recommended course). Average reaction time is 5 sec.

The 400-kg launcher slews at 1.2 rad/sec, with a working circle of 400 mm. Each ammunition suitcase weighs 65 kg (630 × 785 × 135 mm).

The name means antimissile self-defense decoy mini-system (*Mini-dispositif d'Autodéfense pour la Guerre Antimissile Infra-rouge et Électromagnétique*).

◆ REM

This new medium-range chaff round was introduced in 1988; as of early 1988, the French navy had not yet decided whether to adopt this chaff. REM can be launched to 250, 500, or 750 m (altitude 50 m) in less than 5 sec, providing a radar cross section of 1200 m² (H-J-bands) for about 2 min.

◆ SAGAIE

SAGAIE is a long-range radar and IR decoy system (*Système d'Autodéfense pour la Guerre Infra-rouge et Électromagnétique*). It is intended to deal with missiles approaching around the entire horizon, confusing the enemy's targeting radars at long range and, in combination with DAGAIE, confusing missile seekers. A typical installation consists of two 10-tube trainable and elevatable launchers (1 on each side), fired from CIC. Each 40-kg rocket carries a 24-kg payload and flies at 250 m/sec (average). The chaff (EM) version fires projectiles radially, to create a large chaff cloud. The subprojectiles of the IR version contain parachutes that lower them in sequence, to prolong the effective life of the IR decoy. Each rocket is fired from its shipping container (330 × 1800 mm, 30 kg containing a 170 × 1740 mm, 40-kg rocket); the entire launcher weighs 1900 kg (empty) and has a working radius of 1.6 m. Range is 8 km for chaff or 3 km for chaff/IR decoys.

SAGAIE. (Compagnie de Signaux et d'Entreprises Électriques)

Used alone, the decoys provide confusion and distraction. With a jammer, they can dilute an attack and cause missiles to home on a false target after the real target has been concealed or after the missile has been distracted by gate-stealing.

SAGAIE will be mounted on board French frigates, destroyers, and aircraft carriers. It will also be installed on board the new Italian *Animoso*-class missile destroyers. In French service, this system is replacing the modified British 8-barrel Knebworth-Corvus system (Syllex). The prototype was tested on board the trials ship *Île d'Oléron* early in 1986, and the first production installation was on board the destroyer *Cassard* (the second was the carrier *Foch*).

Work is proceeding on a future single system to replace both DAGAIE Mk 2 and SAGAIE. Late in 1989 the Italian navy became the first SAGAIE export customer (for the *Animoso* class).

GERMANY (WEST)

ELECTRONICS

◆ DFS 800 SM

This AEG periscope direction-finder was begun in 1987 and announced in the fall of 1989. It is currently (1989) in prototype form. Frequency coverage is 2–18 GHz, extendable to 40 GHz. It consists of an omnidirectional IFM aerial surmounting a monopulse direction-finder, which consists of 4 antennas; it also has an integrated GPS channel. Dimensions: 150 mm diameter × 220 mm.

◆ ES400

Telefunken's automatic signal collection-and-analysis suite covers 0.5–18 GHz (with optional extension to 40 GHz). Radar signals are acquired and analyzed, and their parameters are stored. ES400A is an electronic-intelligence version using a high-gain directional antenna feeding a superheterodyne receiver and an IFM receiver (with its own omni antenna). The tactical version uses an interferometer (monopulse) antenna, compressive receiver, and pulse analyzer. It employs a signal mode library for signal identification. Threats are automatically listed in priority order. The system is software controlled.

◆ FL1800S/FL400/FL1800B/FL1800U/FL1800H

FL1800 is the AEG system in German Type 122 frigates and the replacement for the U.S. WLR-6 in the German missile destroyer upgrade of 1986. FL1800 is also fitted in Type 143A missile patrol boats.

FL1800S covers 7.5–17 GHz. This system is designed to engage a large number of close-in emitters automatically, e.g., a short-range missile attack in the North Sea or in the Baltic. A very high processing rate is achieved by preprocessing before signals are entered into the main computer.

In a Type 122 frigate, the D/F array is mounted at the head of the lattice mast amidships, the omnidirectional antenna (for frequency and other signal characteristics) on a pole atop the bridge. The omnidirectional antenna consists of 5 antennas (for 5 bands) stacked vertically. Each DF array consists of a series of planar antennas mounted on a common base, again to cover 5 bands. The associated quartet of jammers is mounted on a frame at the base of the housing under the Signaal WM25 radome, on the foremast.

The FL1800S system now standard in the German navy is to be upgraded to FL1800S Step II standard. The existing omnidirectional and DF antennas are modified, and a Racal SADIE parallel processor is introduced to handle the expected very high data rates. For ECM, there are a new tracking processor (to achieve almost pulse-synchronous jamming) and a new switching matrix (to deal with multiple threats). Step II employs 8

The omnidirectional (left) and directional (right) ESM antennas of the German FL1800S system. The omni antenna shows a separate cylindrical element for each of its 5 bands. (AEG)

TWTs facing in different directions, rather than the more common technique of time-sharing a single signal generator. TWTs not needed to jam in their directions can be switched to the threat directions. Displays are also being modified to provide a

Elements of the German FL1800S system. The OD (omnidirectional) antenna feeds an IFM. (AEG)

FL1800S on board a German fast patrol boat. The DF antennas are below the Signaal "egg" radome, and the jamming antennas are above the sides of the bridge. (AEG)

clearer color picture. Finally, the German navy requires some indication of threat range, the ESM system being used to trigger RAM defensive missiles. Step II estimates range using the amplitude of the received signal.

Step II is the basis of a modular family of systems for small patrol craft, submarines, and maritime-patrol aircraft. FL1800S (*Schiffe*) is the frigate or large-ship version. FL1800B (*Boote*) is the fast-patrol-boat version; FL1800U is the submarine version; FL1800H is the maritime-patrol-aircraft or helicopter version.

For compactness, AEG combined omnidirectional and DF antennas into a single biconical antenna. FL1800 is a modular system, so different elements can be updated separately. Alternative antennas include a directional dish as well as the IFMs and monopulse DF arrays. There are also special submarine masthead antennas (dome plus 4 small domes pointed horizon-

FL1800S on board the German frigate *Karlsruhe*, 1990. The omni antenna (for IFM) is carried between the STIR antenna and the Signaal "egg," and the usual pair of jammers is visible just above the bridge windows. The DF array is in the masthead radome. (G. Arra via *Ships of the World*)

tally) and an airborne version (pairs of cavity-backed spirals for 2 frequency ranges). Modifiable function blocks (such as classification, emitter-data bank, display and symbolism, and interface control between the ECM component and the central computer) are implemented in flexible software modules run on standard microprocessors. The microprocessors can be fitted into standard VME-bus computers.

FL1800B uses a combination omni and DF sensor stack (4 nested omni antennas, with monopulse DF antennas around the base, or 2 spiral omni sensors with monopulse DF antennas between and below them). The lighter-weight DF sensor is designated DFS 800B. The simplest associated jammer is a rotating high-gain antenna fed by a TWT. A heavier installation uses a stabilized high-gain directional ECM antenna that occupies a small radome forward of the WM20-series radome. It is fed by 6 or 8 TWTs. This system is designated GAS 800B. The system as a whole can be equipped with 1 or 2 color displays. The submarine version, FL1800U, can use 1 of 2 antennas, a masthead array of an omni and 4 DF sensors (DFS 800 SM), and a periscope head (USK 218) carrying radar, ESM, SatNav, and other communications antennas. FL1800U uses a special "snapshot" technique, scanning the spectrum within a few seconds to generate visual and aural warnings and, thus, avoiding undue exposure.

FL1800H can operate as a cockpit warning system, or it can support a 2-display, color, analysis console. A highly directional DF sensor (presumably a trainable high-gain dish) can be added for ASW and maritime surveillance. The system is built around a data bus, and it can, therefore, accommodate other sensors such as laser, IR, and missile-approach warners. The typical array consists of 6 pairs of cavity-backed spirals, each consisting of 1 large spiral and 1 small (half the diameter of the large 1).

◆ Octopus

For details of Octopus, a new patrol boat system, see the United Kingdom section below (Racal is the main contractor).

FL400 is a smaller derivative of FL1800, for export. There are 3 modules: FL400A, for ELINT; FL400U, for ESM; and the FL400G jammer. Normally FL400U drives FL400G. These systems were all designed for small patrol boats, but they have also been offered for ground use.

FL400A uses an enclosed masthead radome containing 3 omnidirectional antennas over a rotating high-gain reflector for direction finding. The fixed antennas feed an IFM. The frequency range is 0.5–18 GHz, with an optional extension to 40 GHz (higher frequencies are down-converted into the standard range for analysis). FL400U covers the same frequency range, and it is not clear to what extent the FL400U antenna differs from that of FL400A; FL400G is a 20–60 kW noise and deception jammer (7.5–17.5 GHz).

◆ ASDF

AEG's Advanced Shipborne Direction-Finder was introduced in 1985 to achieve high bearing accuracy (particularly in HF) by suppressing reradiating fields to eliminate ambiguities almost completely. Special wide-band antennas, with nulls at various bearings, can help eliminate receding targets. The A1288 antenna consists of a crossed-loop unit plus a parallel-loop unit to create nulls directed at the presumed locations of fields reradiated by the ship. The processor is designated PST1288.

ASDF antenna. (AEG)

◆ PST 1720

AEG's communications intercept and direction-finding system was adopted for the ANZAC frigate. It covers the 10–500-MHz band. The associated PSI 1720 is an interferometric direction finder.

◆ Telegon/ASDF

Telefunken's HF/DF systems (TELEfunken GONiometers) break down into 2 series: odd numbers denote single-channel receivers, even numbers Watson-Watt 3-channel receivers. Most or all naval versions are Watson-Watt HF/DFs. The single-channel receivers are classical goniometers sampling different directions in sequence. Because they must tune only a single channel to a new frequency, they can rapidly scan through a

wide frequency range (330 MHz/sec in the current Telegon 11) to deal with frequency hoppers. On the other hand, because the Watson-Watt continuously monitors all directions (its channels are north-south, east-west, and omni for sensing), it can detect very short signals.

The advantage of the single-channel system is that it can scan over frequency much faster than a Watson-Watt, all of whose channels must be tuned in parallel, and all of whose channels must have their gains (in amplitude and phase) set together to match signal amplitude. The classical calibration technique is sequential sampling of the 2 DF channels, but it is too slow to deal with very short signals, as in burst or pulsed communication. Telefunken developed its own parallel calibration method for this purpose. The system generates a calibration signal so that it can automatically recognize that channel calibration is needed, in which case a microprocessor compensates for amplitude and phase differences between the channels and adjusts the gain control.

It seems likely that the Watson-Watt technique was well suited to short transmissions but that the single-channel technique was required to deal with very fast frequency hoppers. Its antenna can be electronically scanned quickly enough to detect most short signals. Typically each antenna of the Telegon 11 has its own electronic goniometer.

Telegon 11 reduces the performance difference between the 2 types by scanning electronically in direction.

Of the Watson-Watt series, Telegon 4 was adopted by the French and Italian navies as well as by some lesser navies. It is carried at the mastheads of the cruiser *Colbert* and the frigates of the *Georges Leygues* and *Tourville* classes. The basic antenna is a flattened egg-shaped radome with whips radiating at angles to it. In Italian ships (the cruisers, the *Audace*-class missile destroyers, the *Lupo*-class frigates, and the *Pietro de Cristofaro*-class corvettes) the egg-shaped radome was often later enclosed in a circular cage, which in turn supports 4 vertical UHF dipoles (an Adcock) and a central sensing dipole. See the illustration of the Egyptian *Ramadan*-class missile patrol boat under the British Cutlass system. The British CXA is a Telegon adapted to submarines.

Telegon 4 dates from about the mid-1960s. It used only the egg-shaped ferrite antenna, which is limited to intercepting ground waves. Telegon 6 was a modular version specifically for the German armed forces and is probably carried on board the current German frigates. It was exported to Saudi Arabia for the *Al Madinah* class. Subsequent Telegons have also been modular in design, and at least some share their receivers with ship communications.

Telegon 8 (PGS 1521) is a current digital system that uses the ferrite egg (antenna AK 1200) to cover 10 kHz–30 MHz. It is tuned either by hand or by keypad and achieves a resolution of 10 Hz (frequency accuracy better than 0.3 parts in 1 million). Output is typically on a CRT display driven by the 3 channels. Typically, a bearing will be accurate to within 1 deg. Telegon 8 can adjust to a 60-dB jump in signal level in less than 10 msec. To compensate for quadrantal errors (frequency-dependent errors caused by reradiation from the metal parts of a ship), Telegon 8 divides its signals into 56 subranges, for each of which it makes the necessary corrections. The system can accommodate 2 different arrays, switching between them. Bandwidths are 0.1, 0.3, 0.6, 1.5, 3, 6, and 10 kHz. Memory capacity is 30 frequencies. Telegon 8 introduced the automatic channel-calibration technique. Development began in 1979, and series production began in 1981–82.

Telegon 10 (PGS 1720) uses additional antennas to cover the range 10 kHz–1000 MHz. There are 3 sections: 0.01–30 MHz, 20–500 MHz, and 480–1000 MHz. Not all are always present, e.g., there is a shipboard system for 20–500 MHz. The full system uses the AK 1200 egg plus 2 sets each of 4 vertical dipoles: A 1269U (UHF) and A 1265V (VHF). Typical large-ship installations are probably limited to VHF. Telegon 10 incorporates 100 memory channels for DF frequency settings. Frequency can be reset, accurate to within 10 Hz, in 1 msec.

Of the single-channel series, Telegon 3 and 5 date from the 1950s, and none is likely to have survived. Telegon 7 covers 20–1000 MHz HF/DF. The associated receiver is E1900, which is also used for communications. Telegon 9 covers 20–500 MHz (extendable to 1000 MHz). Telegon 9 could operate with Telegon 8 to cover the full range 10 kHz–1000 MHz. Telegon 11 (PGS 1655) is the most recent member of the family. The display is either synthetic video of a histogram of signal strength vs. bearing or a conventional directional display with adjacent digital readout. The tuner can scan in wide band at as much as 330 MHz/sec. DF time can be 50, 100, 200, or 800 msec.

Telegon 11 uses characteristic square loop antennas instead of the dipoles and egg of earlier versions. It can also use the standard antennas of the earlier Watson-Watt systems.

The associated V/UHF receiver is E1900/3.

ASDF (PST 1288), the Advanced Shipborne Direction Finder, is a related system introduced in 1985, achieving high bearing accuracy by suppressing reradiating fields to eliminate ambiguities almost completely. This approach is an alternative to the table look-up compensation used by Telegon 8, which cannot deal with very ambiguous signals. Reradiation from a ship's hull and superstructure can be extremely distorting over the HF band (1.5–5 MHz; masts and other antennas dominate the range 4–20 MHz). ASDF adopts a special antenna, A1288, consisting of a crossed-loop unit plus a parallel-loop unit to create nulls directed at the presumed locations of fields reradiated by the ship. Telefunken claims that this approach improves accuracy by at least half an order of magnitude. ASDF was designed so that it could be added to the Telegon 8 receiver, producing on-line correction data that can be fed into the conventional HF/DF system.

EXPENDABLES

◆ Hot Dog/Silver Dog

The 76-mm IR (Hot Dog) and chaff (Silver Dog) grenade decoys are made by Buck-Wegmann. Payloads: 0.9 lb for Hot Dog, 1 lb for Silver Dog. Silver Dog blooms in about 2 sec. The 12 launchers (in 4 groups of 3) are set at 45-deg elevation and 30-deg train.

Hot Dog/Silver Dog decoy launchers. (Wegmann)

◆ Schalmey

AEG-Telefunken's radar (G–K-band)/IR (medium-range) decoys are fired by a trainable launcher, typically 1 each port and starboard, each holding two 10-tube GRP magazines of chaff or IR rockets. Each magazine can be elevated independently between +13 and +63 deg, and the entire mounting is trainable (in 5-deg steps from 0 to 110 deg relative to the ship's centerline). The 70 × 560-mm (2.5-kg) rockets are launched either singly or in salvos of 2 or 3 at 60-msec intervals. There is also an 800-

mm decoy rocket with twice the chaff payload. Reloading is by replacement of a magazine (570 × 587 × 230 mm, 40 kg).

This system has a low magnetic signature and is, therefore, suitable for MCM craft.

HUNGARY

The Hungarian defense electronics industry provided ESM equipment to the Polish navy (Soviet prices were reportedly too high). This equipment is now being marketed. The descriptions below are from brochures distributed at the Bangkok Asian Defence Services Exhibition and Conference in December 1990. This equipment is exported by the Technika Foreign Trading Co. of Budapest; the manufacturers include the Mechanical Laboratory for Telecommunication Engineering and the Electronic Directorate (for DAMA, below). The latter specializes in the design of EW systems; the Mechanical Laboratory makes ELINT and DF equipment.

◆ IU-60

This VHF DF uses 4 vertical, rectangular-loop antennas arranged around a central mast, as in some versions of Telegon. It is an 8-antenna, electronically rotated Adcock, covering the 20–100-MHz range (receiving bandwidth is 15, 30, or 200 kHz; frequency resolution is 1 kHz). The goniometer frequency is 54.25 Hz, and average accuracy is better than 1.5 deg. Measurement time is at least 0.4 sec, and angular resolution is 0.5 deg. The antenna weighs about 19 kg. Antenna dipole height is 1.8 m (base 1 m).

◆ VREV-T/VREV-P

VREV-T is a general-purpose VHF receiver for ESM/COMINT. It can search the spectrum in 100-Hz steps (knob-controlled), or it can search automatically between 2 preset limits with variable frequency steps, or it can scan (continuously check stations in its scan memory; setting and dwell time per channel is about 30 msec). In scan mode the search can be stopped for a set period so that the operator can listen to the emissions of that station and determine its main characteristics. VREV-T incorporates a nonvolatile memory storing 100 prohibited frequencies and 100 sets of station data (frequency, operator mode, bandwidth). Minimum channel spacing is 12.5 kHz. Frequency resolution is 100 Hz, and typically it takes 25 msec to change frequency.

VREV-P is a panoramic receiver showing 10 MHz of the full 20–100-MHz band nearly instantaneously on a 9-in CRT, using 3 microprocessors to control the receiver and synthesizer, to sample and digitally prefilter the received signals, and to control the display. The full scanned band is displayed in 5 lines, each signal being represented by a bar graph (12 steps). Alternatively, the CRT can display 21 lines (80 characters/line) of alphanumeric data. Horizontal resolution is 12.5 kHz/mm; bandwidth is 15 kHz. The readout of data on any signal is by cursor.

◆ DAMA

DAMA is a signal analyzer (signal rates of up to 9600 bits/sec) based on an IBM AT-compatible computer with a 720-kbyte floppy disk and a 27-Mbyte hard disk. Its buffer can accept up to 8 kbytes of data, sampling at 5 kbits/sec.

INDIA

In 1986 India announced that its Armament R&D Establishment at Pune had developed a multibarrel medium-range chaff launcher, which either is, or will be, used on board Indian ships.

◆ Ajanta

This new Bharat Electronics ESM unit is installed on board the new corvette *Khukri*. It has a 1500-emitter library and is used to trigger two 16-barrel chaff launchers, presumably of the standard Soviet small-ship type. The only photograph of the ship published to date shows an installation similar to that of the Selenia INS-3 of the frigate *Godavari*, but the claimed library size is much larger than that of the older Italian system.

INTERNATIONAL

♦ Sea Gnat

NATO's program for a chaff/IR decoy, Sea Gnat is compatible with the U.S. SRBOC (Mk 36) launcher. The decoy deploys chaff and also a hot gas bag (for IR), the 2 drifting together in the wind. In Britain, the contractors are Hunting Engineering (fire control by Thom-EMI), and the launcher is DLB (to be replaced by DLJ). As fitted to a British Type 22 frigate, Sea Gnat employs either the U.S. Mk 36 or a pair of 8-barreled launchers on each side, all 8 barrels apparently sharing the same elevation, the 2 launchers at 2 different (fixed) bearings.

NATO Sea Gnat cartridges: the IR-seduction cartridge is at the top, and the Mk 214 Mod 1 (UK) chaff cartridge below it. (Author)

The NATO Sea Gnat Mk 214 Mod 1 (UK) chaff-seduction cartridge, cut away to show its load. There are 6 sections of chaff payload, and total decoy cross section is comparable to that of a ship. Mk 214 is mortar-launched. It is 1.2 m long. (Author)

The NATO Sea Gnat Mk 216 Mod 0 chaff-distraction decoy, cut away to show its load. Mk 216 is rocket-propelled and has 3 sections of chaff payload. A drogue chute slows cartridge flight. Mk 216 is 1.4 m long. (Author)

Decoys associated with Sea Gnat include the U.S. Mk 214 seduction cartridge and Mk 216 distraction cartridge. Hycor developed an IR cartridge under this program, M-BIRD (Balloon Infrared Decoy), a balloon that floated on the water. M-BIRD did not enter production. The new Sea Gnat cartridges were scheduled to enter U.S. service during 1989.

This program began in 1973, the NATO MoU being written in October 1976 and signed in January 1977. The NATO program was begun in April 1977, the major cost-plus-fixed-fee contract being awarded in September 1977. Integrated system firing tests followed in August 1978, with at-sea development tests in April 1979. For the Royal Navy, Sea Gnat was approved for production December 1985, with limited production in 1986. Reportedly, the delay between tests and deployment reflects problems with the associated IR decoy. A remotely settable fuze is currently (1989) under development by the U.S. Army Harry Diamond Laboratories.

As of 1989, Sea Gnat was being produced for the Royal Navy, and it was a U.S. Navy program. Germany planned to use it on board Type 123 and Type 124 frigates. No Norwegian or Danish application had been announced.

ISRAEL

ELECTRONIC SYSTEMS

♦ EL-1040

Elta's system is found in Taiwanese (GRC) FRAM-II destroyers.

♦ EL/L-8303

Elta's computerized ESM system is for ship, air, and ground applications. EL/L-8303 intercepts, digitizes, identifies, and records signals in the 2–18-GHz range, with an optional extension to cover 0.5–2 GHz; this system can interface with ECM and chaff systems for manual or automatic operation. Features include direction finding, a combined alphanumeric and graphic (bearing/threat level) display, and a comparison with a built-in emitter library. Accuracy: 5 deg in bearing, 1 MHz in frequency; nominal reaction time is 1 sec. Sensitivity (narrow-band) is -80 dBm, and dynamic range is 60 dB.

♦ EL/L-8310

Elta's ESM receiver is for 0.5–18 GHz (with optional extension to cover 0.06–40 GHz).

♦ EL/L-8312

Elta's computerized ELINT/ESM microwave reception and classification system (computer-controlled autoscans, signal acquisition, and display) covers 0.5–18 GHz (optional extension to 60 MHz–40 GHz range). EL/L-8312 is a monopulse DF system. It has 1 operator. EL/L-8312A is an airborne ELINT/ESM system. This system employs the EL/L-8310 receiver, the EL/L-8320 pulse analyzer, the EL/L-8610 computer, and the EL/L-8570 display.

♦ MN-53

Elbit's passive intercept is used in Israeli navy and South African *Reshevs* and Israeli *Romat*, *Aliyah*, and *Sa'ar-II* and *-III* -class missile patrol boats. Reportedly, the ESM/ECM system was designed by the Italian firm Elettronica and manufactured by Elbit. Radar parameters measured are band, PRF, pulse width, and PRF wobble. Modes: manual/automatic direction finding, manual/automatic analysis (based on PRF, pulse width, PRF jitter), automatic printing and recording of radar parameters (frequency, pulse width, PRF, PRF jitter, time of arrival, direction of arrival). In 1 version, there are 3 separate functional receivers. Elbit claims that MN-53 reflects Israeli experience during the 1973 Yom Kippur War. The NS-9000 is an alternative.

♦ NATACS

The Tadiran (Elisra) naval tactical COMINT and DF system was announced in August 1989; it is a version of a land-based system

that has been in service for some time. The DF antenna is a pair of stacked Adcocks for different frequency bands, each consisting of figure 8-shaped loops instead of single vertical elements. They are supplemented by an omnidirectional COMINT antenna. Both feed into a single main computer (DF data are presumably used to help sort omnidirectional signals).

The typical below-decks installation is a pair of equipment racks, one of them carrying a CRT.

NATACS covers a frequency range of 20–500 MHz, optionally extendable to 2 MHz. DF accuracy is within 2 deg. Frequency resolution is 1 kHz. AM, FM, and CW signals can be analyzed. NATACS scans up to 1000 channels/sec. A minimum of 16 frequency search ranges can be preset, with 200 protected channels and a minimum of 150 preset frequencies. IF bandwidths, which determine the degree of information extractable, are 10, 20, 50, and 100 kHz. The system can accommodate up to 32 receivers and tape recorders.

NATACS is installed on board the Singaporean fast attack boat *Victory*.

◆ NS-9000 Series

These AEL Israel (Elisra) EW systems were announced in 1982. NS-9001 is an automatic ELINT gathering system to map emissions (0.5–18 GHz). The display shows frequency vs. bearing. Direction-finding accuracy: 10 deg in X/Ku-bands, 3 deg in S/C-bands. Frequency measurement: 2-MHz resolution. Sensitivity: 70 dBm (omni), 80 dBm (sector). Modes: instantaneous direction finding (IDF), monopulse direction finding (MDF), and search (SDF).

NS-9002 is a simulation van, which can generate up to 256 emitters (frequency resolution 1 MHz, PRF 125 pps up to 250,000 pps, scan rate 100 Hz TWS to 20-sec search).

NS-9003 is an automatic computer-controlled ESM system. Direction finding is monopulse, and the system incorporates an IFM. NS-9003 can be used to trigger chaff, flare, or ECM responses (typically by NS-9005). Direction-finding accuracy is 1 deg in X/Ku-bands and 3 deg in S/C-bands. This version was originally developed for the hydrofoil *Shimrit*.

NS-9004 is an ESM system for submarines.

NS-9005 is a noise and deception jammer (2–18 GHz) that uses steerable antennas to engage multiple threats simultaneously, using spot, barrage, or swept noise, or RGPO, RGPI, AGPO deception. NS-9005 can also produce false targets.

NS-9007 upgrades existing EW equipment.

NS-9008 is an automatic repair facility.

NS-9009 is a compact version for small patrol boats of up to 200 tons. It uses a wide-open receiver for dense (over 200,000 pps) electronic environments (2–18 GHz). DF accuracy is 8 deg, and sensitivity is 35 dBm. The operator has both a tabular readout and a polar display. Visual and audio alarms are activated when specific threat signals are recognized. This system can control chaff launchers, and it can be upgraded to provide IFM. Measured parameters include direction of arrival, band, signal amplitude, time of arrival. NS-9009 computes launch parameters for chaff launchers. The antenna weighs 15 kg, and the display 30 kg.

A faster version of -9003, NS-9010 uses distributed microprocessors for dense environments (over 250,000 pps). It is used against radars in the 2–18-GHz range. It employs monopulse switching direction finding (instantaneous direction finding is optional). NS-9010 uses a multibeam static-antenna array. Accuracy is 3 deg in X/Ku-bands and 5 deg in S/C-bands.

NS-9003 and -9010 both use the Elbit EA-917 lightweight circular receiving array. A typical integrated ECM suite consists of NS-9010 controlling an NS-9005 jamming-and-deception system.

NS-9025 is an airborne standoff jammer for naval and ground applications.

All of these systems were announced in 1981 as the Elisra Compact Naval Electronic Warfare Suite; they were renamed in the NS-9000 series in 1982 (NS-9001 was introduced late in

1982). As of 1985, they had been exported to at least 3 countries and were in Israeli navy service.

Elisra exhibited advanced versions of its existing NS-9000-series naval EW systems at the Paris Air Show in June 1989: the NS-9003 ESM system and the NS-9005 jammer. Elisra claims that the new version of NS-9003 (suffixed PR) can deal with pulse compression, frequency agility, frequency hopping, and wobbled (jittered) PRF signals. NS-9005 PR can produce both noise and deception jamming, and it can be integrated with a multibeam array transmitter (MBAT). Typically, NS-9005/MBAT employs 4 MBATs and 1 exciter, each array covering 90 deg. It incorporates 4 trackers and, thus, can simultaneously deceive 4 threats, and it can be expanded to cover more, with up to 16 trackers available as an option.

NS-9003 PR covers the 1–18-GHz range. Direction of arrival is measured with an accuracy of 1–3 deg for signals of 2–18 GHz. The system employs a total of 60 directional antennas.

Elisra claims that its new proprietary lens technology provides NS-9005/MBAT with high effective power in the 7.5–18-GHz band.

The new systems are the third generation to be produced by Elisra. The company produced its first naval systems about 1978/79, for service in the early 1980s. They were initially ESM devices, integrated with existing ECM. The second generation (NS-9010) entered service in the mid-1980s. It employed new technology in the form of an RKR lens, which was more compact than the earlier spiral antennas. This system was an RWR as well as an ESM system. Its related ECM system was a conventional, mechanically steered antenna but with a very sophisticated exciter employing deception techniques. The new third generation features are concentrated mainly in the ECM portion of the system: an MBAT antenna, high ERP, and very fast switching for transmission and deception.

NS-9001, an ELINT version of the original NS-9003, falls between the first and second generations.

The associated submarine ESM system, NS-9034, is not yet a real product, but rather a design for using existing NS-9000-series components in repackaged form. It is intended to achieve 1-deg bearing accuracy, for targeting. NS-9034 will operate in a moderate pulse environment (about 100k pps). It will use 6 spiral antennas (2–18 GHz), an optional coarse DF array (Elbit-supplied RKR lenses, 7.5–18 GHz), and an omnidirectional array (2–18 GHz) on the periscope mast. Coarse DF accuracy is 6 deg, fine accuracy 1 deg, and elevation coverage +30/–10 deg.

◆ SEWS/Rattler

Rafael's Shipboard Electronic-Warfare System is in current Israeli service. There are 3 elements: GET/RAN-1001, the ESM system; the Rattler jammer; and the MBAT/RAN-1010 microwave lens, which directs jamming power. SEWS itself is RAN-1100. It is possible that the RAN designations refer to larger-ship versions of the basic system since the manufacturer's brochures show *Perry*-class frigates rather than Israeli-size fast attack craft.

GET/RAN-1001 uses a broad-band IFM receiver and a broad-band instantaneous direction finder (IDF), the latter employing RKR lens technology. There are separate omnidirectional (IFM) and directional (IDF) antennas, typically 2 of the latter. Processing is conducted partly in parallel, and Rafael claims that GET can identify such complex signals as chirps, frequency-agile pulses, and staggered or jittered PRFs. Frequency coverage is 1–18 GHz, and accuracy is 2 deg in bearing and 1.5 MHz in frequency. Dynamic range is 60 dB, and sensitivity is better than –60 dBm. Signals are automatically compared to an emitter library, on the basis of frequency, bearing, amplitude, time of arrival, pulse width, scan rate, and pulse coding. The display shows the true and relative bearings of detected emitters. The ECM response is either automatic or operator controlled. In automatic mode, reaction time is less than 1 sec. This device was developed by Rafael in collaboration with a German firm, Litef.

Rattler is a Rafael jammer for air, ground, and naval applications. It can engage up to 3 radars simultaneously, over 2–18 GHz. One high-powered, broad-band amplifier is time-shared among the 3 channels, excited by a lower-powered microwave source. Output power is reportedly greater than 400 W. Development probably began in 1979–80.

MBAT/RAN-1010 is a multibeam array transmitter for ECM. It employs electronically steered lens antennas and can generate several jamming signals simultaneously. MBAT operates over the 7.5–18-GHz range. Each of 32 beams is 6×25 deg, and time to switch between beams is 150 nanosec.

SEWS/RAN-1100 is a shipborne EW suite combining a receiver (RAN-1001 technology), 2 high-ERP MBATs, and a distributed data processor that decides which signals to generate. In July 1990 Rafael announced the supply of several of these systems, using MBAT jammers, to an unnamed foreign navy following harbor and sea trials. That navy was almost certainly Singapore's; the timing of the delivery voyage of the new fast attack boat *Victory* (which was also fitted with NATACS, see above) fits the Israeli announcement.

The Malaysian fast attack boats (Spica-M class) are fitted with a Rafael system but with antennas similar to those of the Italian Newton system.

◆ TIMNEX 4 CH

Elbit's ESM/ELINT system for the 2–18-GHz range has channelized IFM and automatic classification. Mk 1 has been in service on board *Gal*-class submarines since 1982, and Mk 2 will be fitted in the Taiwanese submarines built in the Netherlands. A related ESM system is probably being fitted to Australian *Oberons*, and Elbit and Kollmorgen are responsible for the ESM suite planned for the next-generation Israeli submarine.

The TIMNEX 4 CH is optimized for ELINT rather than for threat warning. In the Mk 2 version, the system has 4-channel IFM associated with an enlarged DF array covering its frequency range (expandable to 0.5–40 GHz). There is also a miniature DF mast atop the periscope, for threat warning (8–18 GHz, accuracy 3–5 deg).

Elbit claims PRF and time-of-arrival measurement accuracy of better than 0.25%; frequency accuracy and resolution (for the associated IFM) are 1.5 and 0.5 MHz. Outputs are frequency, pulse width, PRF, modulation, amplitude, direction of arrival, and time of arrival. The system is designed to deal with up to 100,000 pps. Its emitter library lists 64 radars, including 32 preset threats. The associated computer is a ROLM 1602B (16 bits, 64 keywords). Control is either manual or automatic; the displays are alphanumeric, polar, and rectangular-coordinate.

Elbit uses much the same elements in 3 other naval systems: Timnex-6CH, MN-21, and ST-31. Timnex-6CH is a wide-band receiver (-4CH is narrow band). MN-21 is an IFM, and ST-31 is a direction-finder. Presumably, the MN-53, often listed as an Israeli navy ESM set, is another IFM belonging to the same family. Timnex 4CHV2 (2–18 GHz) equips Australian *Oberon*-class and Israeli Type 206-class submarines.

These systems can be adapted for airborne use.

EXPENDABLES

The current Israeli navy's chaff launcher is a 48-tube unit (sometimes reported as 45-tube) that elevates and trains to form a 3D chaff cloud under computer control (chaff rockets are fuzed to "walk" the cloud away from a ship). This device, which resembles the Italian SCLAR in appearance, was introduced about 1983. It is the launcher on top of the hangar of an *Aliyah* or on the quarterdeck (just forward of the gun) of a *Romat* or *Reshev*. The new *Sa'ar V* has four 72-rnd chaff launchers.

◆ ACDS

Elbit's private-venture decoy rocket system (Automatic C/M-Dispensing System) launches both chaff and flares. It selects

and launches countermeasures on the basis of the threat's character, range, and bearing, and also on the basis of weather and ship's speed. There is a manual backup. The system can control 24 rockets. The typical installation is one 45-barrel or four to six 24-barrel launchers. ACDS was introduced about 1982.

This system is used by the Israeli navy as well as by Chile and South Africa.

◆ Chaff Rockets

Israel's chaff rockets were developed as a complement to the Gabriel missile. The designed range of the missile was much shorter than that of the Styx missiles of the Arab navies, so the Israeli strategy was to induce the Arabs to fire first—and to miss—primarily by using long-range chaff rockets to produce false targets. The superstructures of the Israeli boats were covered with radar-absorbing material that minimized their own radar signatures when the chaff was fired. Styx's effectiveness was further reduced because the effect of the sudden appearance of targets was to force snap firings. The missile used gyros that had to be run up for about 2 min before it could follow its preset course before turning on its seeker.

Wartime experience showed that, despite the deception tactics, some missiles would lock onto (or at least closely approach) the missile boats. Hence the postwar development of short-range chaff rockets and the associated jammers.

The long-range chaff rocket used in the 1973 war was AV-2, carried in 4 tubes per ship, preferably on the superstructure's sides, with a firing box on the bridge. It is a boost-sustain rocket with an altitude fuze, energized from the launcher (so no batteries are needed). The decoy targets appear 1–2 min after firing and persist for up to 15 min.

The postwar short-range chaff dispenser was originally designated SRCR (ship's perimeter-defense radar-decoy system); it used a 6-rnd launcher on a pedestal (described below), carrying a launcher pod. The rocket has a single-pulse motor, and it follows a preselected optimum-operation trajectory. The chaff deploys to form a full decoy within 15 sec, and the decoy persists for 10–15 min depending on the weather.

The 3 current Rafael chaff rockets (as of mid-1989) are:

	Short-Range	Beamtrap	Long-Range
Weight	3.2 kg	6.6 kg	9.4 kg
Chaff	1.75 kg	—	1.3 kg
Diameter	90 mm	115 mm	89 mm
Length	640 mm	804 mm	922 mm
Fin Span	125 mm	115 mm	179 mm

The short-range rocket is typically fired from a 6-rocket launcher on a standard 0.50-caliber machine-gun mount, 3 rockets being carried together in a loading unit. Elevation is fixed at 45 deg. A single firing box controls 2 launchers. Total weight of the loading unit is 22 kg. The 6-barrel launcher is now being marketed in the United States under the designation LADS. These launchers are used by Israel, Chile, South Africa, and Taiwan.

Beamtrap, a newer system that will replace the current short-range rocket, is mounted in a 6-tube launcher on the side of the ship's superstructure; the firing unit on the bridge or in the CIC controls 24 rockets. The typical firing interval is 0.5 sec.

ITALY

◆ BETA

Elettronica's ESM system is found in the Spanish *Descubierta* class. BETA is not integrated into the combat systems. Unlike the later generation of Elettronica systems (such as Gamma and Farad), this one uses a pair of large stabilized cylindrical antennas, which are probably DF spinners. Above each is a spherical radome housing, presumably, a jammer (ELT 828 or its predecessor). The later Elettronica systems all employ monopulse DF.

Beta radomes (a sphere above a cylinder on the side of the tower mast) are visible on board the Spanish frigate *Descubierta*, 1981. (Nick J. Waters III)

◆ CO-NEWS

Elettronica's communications ECM system (VHF/UHF) is installed in the *Maestrale* class. This system, designed for continuous surveillance and intercept, measures bearings and classifies emitters. CO-NEWS uses a high-scan-rate receiver and a fast automatic direction-finder. The antenna consists of 3 stacked arrays, each consisting of 4 vertical dipoles (to cover the full VHF/UHF range) and a switching matrix; intercepted signals are demodulated for surveillance.

◆ ELT 116

Elettronica's radar interceptor is used as part of an ESM or ECM system. Typically such a system covers 2–18 GHz and uses a 4-channel IFM receiver, whose outputs are displayed on 2 CRTs. The system can discriminate between pulsed and CW signals, and an automatic-warning module with a lamp alert can be added. The module can be set to respond to up to 32 emitters. Frequency measurement is accurate to within 0.2%, and sensitivity is -70 dBm.

◆ ELT 123

Elettronica's basic ESM module is similar in principle to ELT 116 above. ELT 123 provides direction finding for both pulse and CW signals and can be programmed to provide automatic warning of particular threats. In the FARAD system, ELT 123 passes its data automatically to an ELT 261 for analysis.

◆ ELT 124

ELT 124 is used for threat warning and D/F; see THETIS.

◆ ELT 128

This communications direction-finder is for air, ground, and naval service on the HF, VHF, and UHF bands. ELT 128 automatically finds the direction of an emitter and provides technical analysis of modulation. The HF antenna consists of half-dipoles or ferrite crossed loops (mobile applications); for VHF/UHF, the device uses an array of active dipoles.

◆ ELT 211

This ESM receiving system is for Newton (see below). This device provides warning of preprogrammed emitters; continuous wide-open angle and frequency surveillance; autotracking of selected emitters; and tactical evaluation (with appropriate symbology on its display). It can interface directly with a command/control system, or it can be part of a larger EW system. Digital processing makes a single-operator design practical. Typically ELT 211 uses a 60-kg masthead unit. ELT 211 employs 5 antennas: 4 omnis (2 cones and 2 cylinders; typically, the cones are mounted over the cylinders) and a monopulse DF receiver in the form of a collar surrounding a mast. The omnis feed an IFM; the collar feeds the main processor separately. ELT 211 can be connected with up to 4 ECM processors.

◆ ELT 224

See THETIS below.

◆ ELT 261

Elettronica's radar analysis module (see FARAD below) provides automatic tracking and automatic analysis of intercepted signals, with continuous surveillance on a panoramic display.

◆ ELT 311

ELT 311 is Elettronica's manually operated jammer. Jamming techniques include noise, deception, automatic, and semiautomatic. For example, the jammer can use spot noise or modulated spot noise against search and tracking radars (conscan types). There are look-through and time-gated circuits for control.

◆ ELT 318

Elettronica's dual-band CW noise jammer operates with either medium- or high-gain antennas. Using variable modulation techniques, it jams search radars and can adapt to new threats. It normally uses 1 or 2 ELT 828 stabilized-antenna assemblies or an ELT 814 omni antenna. This device was announced in 1981.

◆ ELT 361

Elettronica's dual-band CW noise jammer is capable of spot and barrage jamming; see FARAD below.

◆ ELT 511

Elettronica's manually operated jammer is used as part of an ECM system.

◆ ELT 521

This Elettronica high-powered deception jammer uses either directional (in conjunction with a D/F system) or omnidirectional antennas. It has wide frequency coverage, to engage fire-control radars and active and semiactive missiles. ELT 521 can engage multiple targets simultaneously.

◆ ELT 711

Elettronica's radar-identification module is used as part of an ESM or ECM system.

◆ ELT 712

Elettronica's programming unit is used as part of an ESM/ECM system.

◆ ELT 715

This intercept/jamming system is found on board the Moroccan *Descubierta*-class frigate *Lt. Col. Errhamani*. This system lacks the prominent cylindrical and spherical radomes of the Beta system on board other ships of this type.

◆ ELT 716

Elettronica's data-transmission module is used as part of an ESM or ECM system.

◆ ELT 724

This submarine omnidirectional, preamplified warning antenna, for installation atop an attack or search periscope, is available to supplement THETIS. Equivalent Italian ships use Newton.

◆ ELT 814

Elettronica's omnidirectional jamming antenna (receiver/transmitter) is cylindrical; it is normally connected to an ELT 521 deception (e.g., range-gate or speed-gate pull-off) jammer but can also be fed by an ELT 318 noise jammer.

Farad system components. (Elettronica)

◆ ELT 828

Elettronica's directional jamming antenna is generally connected to an ELT 318 noise jammer or to an ELT 521 deception jammer. There are 2 sizes, to cover 2 bands. This antenna is included in the Gamma and Newton suites, and it was reported in 1987 that the PRC's Jianghu-V frigates were being fitted with Elettronica suites including this antenna.

◆ FARAD

FARAD is Elettronica's small-ship system. The core unit is ELT 123 (basic ESM), supplemented by ELT 261 (analysis), ELT 521 (deception jammer), and ELT 361 (noise jammer). Both omni and directional jamming antennas may be used. ELT 123 consists of a warning display, a DF processor, and a pulse-recognition processor. It performs instantaneous direction finding (IDF) of pulse and CW emissions and automatically warns of preprogrammed threat emissions, displaying a symbol indicating the threat family type with the strobe indicating threat direction. The warning display incorporates a small operator keypad. Elettronica describes ELT 123 as a warning and DF system. ELT 123 does not require a dedicated operator. ELT 261 consists of the IFM receiver and the large-screen ESM display, with its keypad, soft keys, and trackball. It recognizes complex mode emissions, identifies emitters, and automatically tracks selected emissions. Elettronica describes ELT 261 as an analysis and identification system. The separate warning display can be deleted when ELT 261 is installed, or it can be retained as a bridge display. ELT 521 and the ELT 814 omni antenna constitute the self-protection portion of the system, and the ELT 361 noise jammer and ELT 828 direction antennas are the masking and mutual-protection elements. ELT 521 is a stand-alone transmitter, with programmable deception routines, different deception techniques, and a capability for multiple-threat engagement (hence the use of the omni antennas). The noise jammer is automatically driven by the FARAD ESM system (ELT 123 and ELT 261).

Elettronica stresses the reprogrammability of the system, and also its ability to transfer data directly into a CDS. The company describes 3 typical configurations:

Patrol: ESM only, ELT 123 with or without ELT 261. The current FARAD brochure seems to associate this system with

Farad installed on board a typical fast attack boat. (Elettronica)

a large coast guard patrol boat. This is probably the system on board Italian *Lerici*-class minehunters and *Cassiopeia*-class patrol boats.

Attack: ESM plus self-protection (deception jammer). An enhanced configuration includes ELT 261 for target identification. The current FARAD brochure shows a *Sparviero*-class hydrofoil in this role. This system, designated FARAD A1, is installed on board the private-venture demonstration attack boat *Saettia*.

Coastal and High-Value Target Defense: The main role is to deny information to the enemy's search and acquisition radars. ELT 261 is necessary, and at the least the craft must carry a noise jammer. In the enhanced version it also carries a deception jammer with an omni antenna. The current FARAD brochures seem to associate this system with the Thai *Praburapak* class, and it is also carried by the *Chonburi* class.

The masthead antenna array weighs less than 25 kg, and each ET 828 weighs less than 50 kg, including stabilization.

◆ G-100

This Eltcom (Elettronica subsidiary) interferometric direction-finder was displayed at Mostra Navale in 1989. Although developed initially for the army, it is intended for triservice use. G-100 covers the 20 MHz–1 GHz band but can be extended up to 2.2 GHz and down to 1.5 MHz. Interferometry, i.e., wide-open direction finding, was chosen for its speed; G-100 is intended to locate medium-speed frequency-hopping radios, burst transmissions, and radar pulses. Minimum acceptable signal duration is 2 msec in VHF and UHF, 50 msec in HF. This performance is appropriate for frequency hoppers at about 400 hops/sec in the VHF and UHF bands. G-100 is controlled by

multimicroprocessor; it can scan 1000–4000 free channels/sec, using a subchannel search technique, or it can search a preset list of 100 channels. The resolution of the display is 0.1 deg, and RMS accuracy is 1 deg at a clear site, after calibration, in VHF and UHF. For HF signals, accuracy is 2 deg with the full antenna array, or 4–8 deg with reduced arrays.

◆ GAMMA

Elettronica's ECM suite covers the 2–18-GHz range in 4 bands. The 4 outputs are displayed on 2 CRTs that can discriminate between pulse and CW signals. Two other CRTs display signal-analysis data, and a fifth gives D-band data. Several jammers are provided, including radar-angle jamming to confuse TWS radars. This system was intended for corvettes and large fast attack boats. It incorporates the same spherical jamming antenna and the same sensing antennas as Newton but uses a simpler processor. Gamma may be the version of Newton intended for ships of 1000–3000 tons, consisting of 1 ELT/211, 1 ELT/318 noise jammer, 2 ELT/828 directional ECM antennas, and 2 or 3 ELT/814 omnidirectional ECM antennas. Newton proper is presumably the version for ships of 2500 tons or more, and FARAD is the version for ships of 250–1500 tons.

◆ INS Series/RQN Series

Selenia's Integrated Naval Systems, INS-1, is for small ships such as fast patrol boats. INS-3 is for large ships. INS-1 consists of an RQN-1 radar detector, a PAW-1 pulse analyzer (with warning), and an optional TQN-1 jammer and an RIN-1 identification unit.

RQN-1 employs an omnidirectional cone antenna (for wide frequency range) plus an array of directional antennas, measuring signal source bearing, pulse width, PRF, and band (L, S, C, and X: a lamp indicates the band). There is no IFM. Coverage

The intercept and direction-finding antenna of an Italian INS-3 installed on the Indian frigate *Godavari*, 1986.

INS-5 is the latest of a series of Selenia jammers. They are generally mounted on masts, without radomes. (Selenia)

is 1–12 GHz (but the system works up to 18 GHz), and nominal sensitivity is 48 dBm. Directional accuracy is 5 deg for the 2–12 GHz range, PRF is measured to within 10% for 50–10,000 pps (displayed on a 3-in CRT), and pulse width is measured to within 10% between 0.3 and 5 microsec. Bearing is indicated by a CRT strobe.

The designation INS-3 indicates Integrated (ESM-ECM) Naval System, third generation. Selenia characterizes the first generation as having separate analog video displays for D/F and frequency measurement and as using a digital analyzer. In dense environments, it could be difficult to correlate a strobe with the associated pulse characteristics. Second-generation systems introduced a frequency-bearing (situation) display, for quick analysis and unique D/F-frequency correlation. A system of this type was successfully tested on board an Italian corvette but

did not enter production. However, the second generation led directly to INS-3, whose main feature is automatic data extraction, done by a processor that carries out automatic analysis in real time and that controls active countermeasures. Compared with the second-generation display, INS-3s associate an identification symbol with each intercept. The processor maintains an active radar file of up to 64 emitters and can provide warning of up to 32 preprogrammed threats. There are 2 intercept channels, to cover the full 1–18 GHz range. For DF, there are 8 fixed antennas surrounding the omnidirectional antenna feeding the IFM processor. Directional accuracy is 5 deg.

INS-3 is built around a digital interceptor (RQN-3), with instantaneous frequency measurement for 1–18 GHz and with automatic control of chaff launchers. It is usually associated with the RIN-1 digitally augmented display system, which includes an RQN-3B for automatic detection, analysis, and tracking. Threat library capacity is 3000.

The ECM section is designated TQN-2; it receives data for automatic reaction (noise and pulse jamming, as well as chaff and flare control). The stabilized jamming antenna automatically tracks its target by 2-channel monopulse (the DF array provides coarse data) and emits noise over a range of 6–18 GHz. Beamwidth is 3 deg. There is a second 6-deg beam used to avoid the nodding effects due to multipath reflection at low elevation angles. A separate ULQ-2 deception unit can be added, to modulate the jamming signal for range and angle deception. The system can also provide passive tracking data to other self-defense weapons.

INS-3 is based on a helicopter system, IHS-6, which uses an RQH-5 receiver and a TQN-2 jammer.

The latest system in the series is INS-5, employing the RQN-5 receiver and the TQN-2 active jammer of the INS-3 system. The system can track up to 50 emitters, and its threat library contains 3000 emitters. Emitters are tracked both in bearing and in elevation (as in the case of aircraft and missiles).

INS-3 employs an ND-160 computer and a specialized hardware processor to sort the received pulses, as well as a hardware-based pulse analyzer and a signal identifier. The 16-in circular CRT can be arranged to show 2 alternative displays, a B-scan (frequency vs. bearing, with signals identified by track number and by standard NTDS symbol), and a PPI display similar to that of SLQ-32, in which the range rings correspond to degrees of threat. In each case the screen also shows 2 alphanumeric displays: a list of track numbers with category symbols, and a list of signal characteristics (track number, band letter, minimum and maximum frequency in MHz, PRF, pulse width, and identification).

These Selenia systems can be recognized by the characteristic single omni/DF antenna. RQN-1A/B uses a cone atop a cylindrical section (the 2 are not separated, and they are more massive than the corresponding Elettronica components); this antenna is mounted at the masthead. The cone houses a spiral antenna, which will detect circularly polarized radiation. The frequency characteristics of this type of antenna are determined by its apex angle, and bandwidth by the rate of spiral around the cone. The cylinder below it houses a series of directional horns operating at various frequencies. Dimensions: 38 cm in diameter, 76 cm high (30 kg weight). INS-1 used the same antenna. RQN-3 uses a different IFM/DF antenna (illustrated) with a blunter cone, but it is still a single unit, unlike the multiple antennas associated with the Elettronica systems. The blunt cone is 76 cm high, including the base containing the directional antennas, and it is 44.2 cm in diameter; the maximum width across the directional antennas is 86 cm. The entire assembly weighs 18 kg. The standard directional jammer, illustrated here, is never enclosed in a radome. The 4 square antennas (horns) alongside the main dish are used for monopulse target tracking.

Because it did not adopt this system for its newer frigates and destroyers, the Italian navy allowed it to be exported to Iraq and Libya for their *Wadi M'ragh*-class corvettes. INS-3 was later adopted for the Italian *Minerva*-class corvettes.

◆ Newton

Elettronica's larger-ship alternative to FARAD has been exported to Spain (*Lazaga* class) and to Thailand (PFMM Mk 16, or *Ratanakosin*, class). The related but more sophisticated Lambda (or SLQ-D/SLR-4) is used on board *Maestrale*- and *Lupo*-class frigates. The system is built around the ELT 211, which employs parallel omni and DF channels feeding its operator console/processor. There are 4 omni antennas: 2 cones ("witch hats") and 2 cylinders. Elettronica uses omnidirectional cone ("witch hat") antennas for HFs. The cylindrical radomes cover half cones. They feed an RF unit. The DF antenna is a monopulse collar mounted around a mast, feeding through a mast-mounted service module box. The mast elements weigh about 60 kg, and ELT 211 weighs about 450 kg altogether. ELT 211 automatically analyzes and displays emitter parameters, matching them with its library; it displays threat identification symbols; it automatically tracks selected emitters; and it warns automatically of preprogrammed threats. ELT 211 automatically indicates a preferred ECM reaction, and it can drive up to 4 jammers. Like FARAD, it drives its associated noise jammer (ELT 318). Unlike FARAD, it is connected directly to the ELT 521 deception set. In a ship carrying both types of jammers, either can be switched to either the directional or omnidirectional antenna. The single operator at the console controls all ECM and ESM functions. Because it can transfer information into a ship's CDS, Newton can easily be coordinated with other active countermeasures, such as chaff launching and missile firing.

Elettronica offers 3 basic versions:

100–500 tons: ELT 211 with either noise or deception jamming for self-protection. In the deception version, only the omni antenna is used; for noise, only the directional one. The brochure shows the silhouette of a fast attack boat. The brochure also shows the system antennas on board what appears to be a

Newton system components. (Elettronica)

Newton on board a Spanish *Lazaga*-class fast attack boat. (Elettronica)

Spanish *Lazaga*-class fast patrol boat, with a pair of the directional antennas.

250–1500 tons: ELT 211 with both noise and deception jamming, and with both types of antenna. The silhouette in the Elettronica brochure is that of a *Descubierta*-class frigate, and that suggests that Newton may have replaced Beta on board some of the Spanish ships.

1000–3000 tons: ELT 211 with 2 deception jammers and 2 directional antennas, or with that suite plus 1 noise jammer and a third directional antenna. The brochure shows the silhouette of a *Lupo*-class frigate. The Italian *Lupos* show radomes or en-

The Italian frigate *Maestrale* is equipped with the Lambda (SLQ-D/SLR-4) system. The cylinder above her bridge is an ELT 814 omnidirectional jammer. A similar centerline radome is mounted atop her helicopter hangar. (Coll. S. Cioglia)

closures (presumably for jammers) at the after ends of their forward superstructures. The similar *Maestrale*s show a pair of omni radomes at the ends of their superstructures.

Over 2500 tons: ELT 211 with 4 jammers and 4 directional antennas (either 1 noise and 3 deception, or 2 noise and 2 deception). The brochure shows the silhouette of a "Standard" frigate, but no such installation has been announced.

The objects at the ends of the yardarm high up the mast of the frigate *Aliseo* are the IFM antennas of her SLR-4 system. In some *Lupo*-class frigates, the mast is surmounted by a Telegraf HF/DF. (L. Grazioli)

◆ MM/SLQ-D and MM/SLR-4 (Lambda)

This combination, rather than Newton, is the ECM/ESM system of the Italian navy's *Lupo*- and *Maestrale*-class frigates. The antennas resemble, but are not necessarily identical to, those of Newton, but the processing system is quite different. Newton uses a wide-open ESM system. SLR-4, the ESM component of the Italian naval system, incorporates a superheterodyne receiver for better frequency discrimination. Earlier Italian naval systems (for the cruisers and for the *Audace*-class destroyers) also incorporate superheterodyne receivers.

Lambda is the commercial designation for this system. It was exported to Peru and Venezuela (which has now replaced it with Guardian Star) but not, despite reports, to Iraq. Iraq received the Selenia INS-3, which the Italian navy had not, as of then, adopted; later the Italian navy did adopt it for *Minerva*-class corvettes. Ecuador received the similar but less sophisticated Gamma.

◆ Nettuno/Nettunel

Elettronica's ECM system was ordered for the carrier *Garibaldi* in 1983; it is also on the hydrofoil *Sparviero*. It is either closely related to, or identical to, the Nettunel of the Spanish carrier and *Santa Maria*-class frigates. The ESM subsystem employs 4 omnidirectional antennas (a cone and 3 pot-shaped radomes) feeding an IFM and pulse measurement receiver, plus a pair of roll-stabilized, multibeam, high-band, directional antennas (fore and aft) and a circular, low-band, DF antenna (an array of spirals). Pulse data are automatically extracted for emitter analysis and identification (the size of the emitter library is not given). Direction and frequency are measured on a pulse-by-pulse basis, presumably for de-interleaving.

Elettronica Nettuno (Nettunel) jammer on board the Spanish frigate *Numancia*, 1989. (S. Terzibaschitsch)

The Nettuno system. (Elettronica)

Passive elements of the Elettronica Nettuno (Nettunel) system are shown on the mast of the Spanish frigate *Santa Maria*, 1989. The object at the masthead is a TACAN. Below it the mast is encircled by the low-band DF antennas, a series of 8 cavity-backed spirals. The short yardarm below carries 4 omni antennas, for IFM in various bands: a cone over a short cylinder on the left, and 2 short cylinders (above and below the yard) on the right. The double-cylinder on the main yardarm below that is the high-band DF antenna. The 2 high-band DF antennas can also be carried fore and aft, rather than port and starboard. The radar on this level is SPS-64(V). Both the high-band DF antennas and the jamming antennas are roll-stabilized, and both are electronically steered. (S. Terzibaschitsch)

The ESM subsystem has its own display, and it also feeds both the ELINT and the ECM subsystems. The former has an analysis console and an associated recorder. The PRF and antenna patterns of selected emitters can be displayed, together with the effectiveness of countermeasures.

The ECM subsystem employs a pair of antenna/transmitter units, port and starboard.

In the Nettunel on board the Spanish frigates, the low-band

array is mounted at the mast head, just below the TACAN antenna, in the form of 8 D/F panels. The 4 omnidirectional antennas are mounted on the cross trees and are similar to those of Newton (ELT 211), except that Nettunel uses 3 pots and 1 cone whereas Newton uses 2 pots and 2 cones. The 2 high-band D/F boxes are at the yardarm ends; they are about half the size of the bigger jammer boxes on the superstructure. Both the high-band D/Fs and the jammers use dielectric lenses to achieve high angular resolution.

• Nettuno/Nettunel is descended directly from Newton (below).

◆ MM/SPR-A

Elettronica's ESM system for the Italian navy is presumably a version of 1 of the commercial systems listed. Coverage is 1.0–10.5 GHz, using 4 fixed omnidirectional antennas to achieve wide-open performance in bearing. The system employs crystal video receivers; it has no associated IFM. Emitter bearing is indicated by a strobe on the CRT display.

This system appeared in the late 1970s.

◆ RQN Series

Selenia's signal receivers are associated with digital data-analysis threat libraries. RQN-1 operates over 1–12 GHz; -1A over 1–18 GHz. Outputs are bearing, frequency band, pulse width, and PRF. Directional accuracy is 5 deg. With the addition of a special module, RQN-1 can provide automatic warning of up to 8 selected threats. Sensitivity is 48 dBm. RQN-3 uses an IFM, and its sensitivity is 65 dBm.

◆ THETIS

Elettronica's submarine ESM system provides threat warning (via frequency measurement) and direction finding. The name

The Italian submarine *Sauro* displays the antennas of her Elettronica Thetis ESM system (left and right), as well as her BPS-704 radar antenna. (*Ships of the World*)

means Threat Evaluation Tactical Information System. THETIS is available in 2 configurations, ELT/124-S and ELT/224-S. The basic system gives threat warning and direction finding only; the more sophisticated version also gives full ESM (it adds an IFM receiver and full ESM display). Both versions use the same D/F antenna (1 conical spiral omnidirectional antenna plus 8 plane-spiral D/Fs assembled in a single casing to withstand pressure), and both can be fitted with a separate omnidirectional antenna (ELT/724-S) with preamplifier, which can be mounted on the attack or search periscope for primary warning before surfacing.

◆ Breda 105-mm Rocket Launchers (SCLAR)

There are 2 types, a 20-rocket trainable and elevatable launcher and a light-chaff launcher.

The 20-tube heavy launcher is part of the SCLAR system, which has been successfully exported. The launcher consists of 4 horizontal rows of tubes; weight is about 1150 kg empty or 1750 kg loaded. The launcher trains at 60 deg/sec and elevates at 30 deg/sec (limits +55/–3 deg). Firing rate is approximately 1 rocket/sec. Working circle is 1.38 m.

This launcher can also fire illumination and bombardment rockets. Rocket types are chaff distraction (range 12,000 m), chaff seduction (5000 m), IR seduction (5000 m), illumination (4000 m), bombardment to support a landing force (11,000 m), and coastal bombardment (11,000 m). Rockets are carried in waterproof containers with frangible heads. The launcher itself can be modified to accommodate 81-mm or 127-mm rockets (e.g., 24 × 81 mm or 12 × 127 mm).

The original 20-rnd launcher system was designated UCLAR. SCLAR, which was funded as part of the *Maestrale* program, introduced a digital microprocessor based on the Elsasg ESA-24. It stores a large number of alternative decoy patterns, any of which can be chosen based on such circumstances as the nature of the threat and weather conditions. One processor drives 2 launchers, setting train and elevation and programming decoy firing patterns.

As of early 1989, a total of 128 SCLARs were in service, with another 28 on order. The first units were ordered in 1978.

At the 1989 Genoa show, Breda exhibited a new version of its SCLAR chaff launcher, carrying 2 sets of tubes for a total of 6 French Mistral short-range missiles atop it. A television cam-

Breda's 105-mm rocket launcher, for both decoys and shore bombardment. (Breda)

era is mounted between the Mistral tubes. Control is exercised from a 1-operator below-decks console incorporating a television monitor and a joystick. The daylight television can be replaced by a low-light or IR unit for night operation. Typically, the mounting receives target designation from a 2D or navigational radar, the operator slewing it onto the designated bearing and then searching in elevation. It begins to auto-track optically when it is within 0.5 deg of the target.

Long-range chaff can be launched, followed by missiles when the target comes within range, and then followed by short-range chaff in the event the defensive missiles fail. The entire launcher is stabilized and remotely controlled.

Total swept radius of the launcher is 1.380 m; elevation limits are $+57/-4$ deg. Total weight, including 20 rockets and 6 Mistrals, is 2150 kg (1430 kg empty). Training velocity is 60 deg/sec (elevation rate 30 deg/sec). The manufacturer estimates that the 6 Mistrals can be reloaded manually in less than 5 min.

The light-chaff dispensing system uses only short-range rockets, for distraction or seduction; this system is intended for craft too small for the 20-tube launcher. Rockets are carried packed in their fiberglass shipping containers, and the 6 tubes of each launcher (port and starboard) are fixed in elevation (35 deg) and in train (45 deg from the centerline), in a chassis fixed on the deck. Typically 4 tubes face onto each bow, and 2 onto each quarter. The system can fire 1 rocket onto each bearing, or 4 onto all 4 bearings (045, 135, 225, and 315 deg), or 2 onto the 2 bow bearings.

Each 6-round launcher weighs 105 kg empty or 145 kg loaded. Each short-range rocket weighs 5.2 kg; and when fired at a 35-deg elevation, the rocket reaches a maximum altitude of 100 m (300-m range) in 4.426 sec, and falls into the water in 9 sec (range about 560 m). The rocket is designed to burst at 80 m (to ensure a cloud duration of about 2 min, with a reflecting area of 800–1200 m² on I/J-bands).

JAPAN

The earliest modern Japanese naval EW systems were NOLR-1A and -1B, which were comparable to U.S. mechanically scanned units (WLR-1 series). They were succeeded by NOLR-5, a radome-enclosed antenna on board some frigates. These devices could not scan the frequency bands quickly enough to detect antiship missiles. The electronically scanned NOLR-6 appeared in the early 1970s; it covered the spectrum up to 18 GHz. It had 2 rotating direction-finding antennas to cover the main radar bands, plus a circular dipole array on the foretop for direction finding in the VHF/UHF band. NOLQ-1 was introduced in 1980; it is an electronically scanned array, comparable to the U.S. SLQ-32, typically integrated with 2 OLT-3 deception jammers (1 on each side) and with MK 36 decoy launchers.

EW systems on board the Japanese destroyer *Asagiri*. The masthead radar is OPS-28, the cruise-missile detector analogous to the U.S. TAS Mk 23; OPS-28 is used in conjunction with the radome-enclosed FCS 2-12E aft, which controls the Sea Sparrow (launcher on the stern). The fire-control radar forward is FCS 2-21A, and the air-search radar is OPS-14C. NOLR-6 combines equipment on both masts. (JMSDF)

EW systems of the missile destroyer *Hatakaze*. NOLQ-1 combines the masthead array, the antenna just forward of the main air-search radar (SPS-52C), and the flat array at the base of the big lattice mast. The 2D radar aft is OPS-11C, and the slotted array at the masthead is the OPS-28B anti-sea-skimmer set. (JMSDF)

◆ Fleet ECM Policy (1988)

The main current systems, with their U.S. equivalents, are:

NOLR-6 very similar to WLR-8

NOLQ-1 very similar to the U.S. SLQ-32(V)3

NOLQ-2 currently under development

OLR-9 very similar to WLR-11

OLT-3 very similar to SLQ-17

OLR-9 mainmast array (at maintop) and NOLR-6 mainmast array (radomes on platform) on board the destroyer *Amagiri*. The position of the cylindrical radomes varies among units of the class. The big radome is for Sea Sparrow fire control (FCS 2-12E). (Sea Power)

ZLR-3/5 warning receivers, very similar to WLR-8

ZLR-4/6 ESM systems, very similar to WLR-1G

Surface units will have the following systems:

DDH, DDG—NOLQ-1 (ESM/ECM), Mk 36-2 SRBOC

DD—NOLR-6 (ESM), OLR-9 (WR), OLT-3 (ECM), Mk 36-1 SRBOC

DE—NOLR-6 (ESM), OLR-9 (WR), Mk 36-1 SRBOC

After JFY88, NOLR-8 will replace NOLR-6 and OLR-9. New ships after JFY90 will have NOLR-8 and Mk 36 SRBOC.

Submarines have ZLR-4/6 (ESM) and ZLR-3/5 (WR); new submarines after JFY88 will have NZLR-1.

Aircraft:

—P-3s have ALQ-78 or ALR-66(V3)

—P-2Js have HLQ-101 (domestically developed)

—SH-3Hs have ALR-66(V1)

—SH-60Js have HLR-108 (domestically developed)

The big radome just above the Phalanx on board the *Amagiri* is an OLT-3 jammer (another is just visible on the other side of the ship). Somewhat similar radomes, aft on board older ships, are U.S.-type DF spinners. (Sea Power)

NETHERLANDS

Signaal and the British MEL company were both members of the Philips group, and Signaal transferred its countermeasures systems to the British company in 1985. In 1989 Philips announced that it would sell off its defense companies, and control of Signaal went to the French company, Thomson-CSF. Signaal/MEL products are listed here under the original parent company.

◆ RAMSES/Scimitar

Signaal's Reprogrammable Multimode Shipborne ECM system is a noise and deception jammer (I/J-band) that uses a pair of egg-shaped masthead or yardarm radomes (350-mm diameter × 1100 mm, 25 kg each). The antennas inside rotate and are stabilized.

The jammer is automatically controlled by a processing cabinet although there is also an emergency local-control panel. Typically, jamming is triggered either by the ship's tactical data system or by an ESM system, such as Rapids. The jammer is fed with target characteristics (based on ESM data) and bearing;

NOLQ-1 arrays on board the destroyer *Haruna*, with an OPS-11C radar above them. They presumably correspond to the lens antennas of SLQ-32. (Sea Power)

Commissioned in 1990, the escort *Abukuma* shows a new ECM suite that includes a pair of lens antennas on a platform above her forward fire-control radar. This combination is presumably NOLR-8. (Ships of the World)

Ramses jammer (2 radomes, separated vertically, with radiation-reflecting plates between them) on board the former Dutch cruiser *de Ruyter*, now in Peruvian service. The radar above is DA-08. (Signaal)

1 of the 2 antennas is assigned to the threat and slewed onto it. Meanwhile, the jammer looks up target characteristics in its own look-up library. Its upper (receiver) antenna goes into a search mode around the designated bearing, seeking a target that matches library information. Once it has locked on, it tracks and then triggers a preprogrammed response (via the lower, transmitting, antenna) as determined by Function Generators in the processing cabinet. The RF cabinet contains 2 TWTs, 1 for CW (noise) and 1 for pulsed (deception) jamming. Typically, the jammer uses noise against target-acquisition radars and pulse jamming against the seekers of antiship missiles. Signaal claims that noise jamming can be effective at ranges as great as 180 or 200 km.

The separate tracker antenna, identical to the jammer antenna, makes it possible for the jammer to operate continu-

ously, without pausing to look-through and check the status of the target. Identical antenna characteristics make for more precise jamming, which is particularly valuable against distant targets. Given 2 antenna systems, 1 on either side of the ship, the jammer can deal with 2 targets simultaneously. Also, because the processor cabinet contains 2 function generators, the jammer can set up a jamming sequence for a second target while the first is being jammed, and switch over as soon as needed.

The fundamental deception mode is false-target generation (the jammer sends back an exactly similar pulse). The responses can be modulated in strength to deceive sequential tracking radars such as conscans; this mode is, however, ineffective against monopulse seekers. Other standard jammer tactics include range-gate pull-off and swept scan rate modulation (SSRM), the latter a form of angle-gate pull-off useful against search radars.

A NATO version of RAMSES, Scimitar is a reprogrammable noise and deception jammer for the 8–16-GHz band, intended primarily to deal with missile seekers and target-indication radars. Jamming modes include noise (either spot or wide band), range-gate seduction, inverse scan gain, and false-target generation. Power output is 1.0 kW in pulse mode and 100 W in CW mode (later increased to 1.5 kW and 150 W). Scimitar can jam several radars (with different characteristics) simultaneously, as long as they are all in its beam. The 2 antennas can track 2 separate radars simultaneously. Beamwidth is 7×7 deg (gain 23 dB), and frequency sensitivity is 60 dBm.

Scimitar, with its own receiver, can be used as a stand-alone system if the associated ESM system fails.

See also the Canadian SLQ-503 above.

German-built FS-1500 frigates carry RAMSES. An order for units to equip the Argentine MEKO frigates was canceled because of the Falklands War. There is some question as to whether the full installation planned for the Peruvian cruisers was ever completed, as some equipment had to be postponed for financial reasons.

◆ Sphinx/Rapids

The ESM arrays around the mast (under the DA-08 radar) of this Dutch *van Heemskerck*-class missile frigate serve Rapids. The antennas on the mast are omnis for the system's IFM. (Signaal)

Sphinx (System for Passive Handling of INtercepted Xmissions), the Signaal ESM system, was later taken over by Signaal's partner, MEL. It incorporates a wide-open DF array under the Signaal "egg"; its sensitive IFM, with digital output, uses 3 mast-head antennas. Sphinx automatically warns of radar lock-on and automatically analyzes and tracks selected signals. Selected sig-

RAMSES, SLQ-503. (MEL Defense Systems)

signals tracked in bearing, or selected sectors, can be blanked out. Sphinx exchanges data with associated ECM (e.g., Ramses) and CDSs. Frequency coverage (1–18 GHz) can be extended to 33–40 GHz. Other optional features: threat warner with 12 preprogrammed channels, and a CW detection package.

The DF antenna has 8 sectors, each of which contains 5 antennas, including a horizontal cone. Vertical coverage is 40 deg. Sensitivity: –65 dBm for the IFM, –40 dBm (37 dBm in J-band) for the bearing antenna (–65 dBm for the high-sensitivity bearing antenna). Dynamic range is 65 dB. Frequency is measured within 0.125%, and bearing to within 4.5 deg (5.5 deg for the high-sensitivity mode). Resolution: 5–10 MHz and 1.4 deg. Measurable pulse width is 0.1–100 microsec, PRF 100 Hz–56 kHz, and scan period 0.1–80 sec. Sphinx can track 14 signals and can lock onto and trigger a warning of 3 signals. Signals are presented at 3 strength levels. Processing time is about 2.5 microsec/signal. There are 3 displays: a circular CRT (situation display) shows bearing vs. frequency, and 2 alphanumeric displays show pulse analyzer output and emitter identification.

The bearing array's diameter is 2.156 m (height 1.189 m, weight 560 kg). Frequency aerial diameters $\times$ heights: 250 $\times$ 268 mm, 185 $\times$ 251 mm, 357 $\times$ 335 mm, 610 $\times$ 415 mm, and 280 $\times$ 470 mm (1 large cylinder and 2 pairs of smaller ones, all with axes vertical).

The associated computer is SMR-4.

The Sphinx antenna is probably identical to the A2 version of the contemporary MEL Susie, which uses a less capable processor. Signaal almost certainly originated the idea of wrapping the antenna around the base of its "egg," and MEL and Signaal were both associated Philips companies when Sphinx and Susie appeared. MEL was ultimately given responsibility for producing and marketing Sphinx.

Sphinx first appeared on board the Dutch Standard frigates, the first of which entered service in 1978, and it is probably also the ESM system of the Argentine MEKO 360-class frigates (which carry Scimitar jammers).

Rapids (Radar Passive Identification System) was intended as a less complex successor, using next-generation technology (an SR-MU computer with additional bearing-and-frequency analysis racks, and a cursive, rather than analog, display). MEL, which now markets the system, claims that it is descended from CANEWS. Initially, about 1981, Rapids was described as a less

capable system, covering 8–18 GHz but expandable down to 2 GHz, with a sensitivity of 60 dBm, a bearing accuracy of 3.5 deg, and a frequency accuracy of 5 MHz. The *van Heemskerck*-class missile frigates use a DF antenna similar to that of Sphinx. Another version, in Turkish MEKO frigates and in Malaysian FS-1500-type frigates, uses the Anaren DESM antenna also used in Cutlass B1. The last 2 Turkish frigates use Cutlass B1.

Rapids operates on 4 bands (2–4, 4–8, 8–12, 12–18 GHz). Pulse parameters are digitized and fed to a processor that sorts the pulses into identifiable radar signals (de-interleaves). Its output is then further processed to give radar parameters. The display is synthetic rather than raw video; it shows frequency against bearing, with alphanumeric information alongside (radar number, name, threat, CF, purpose, category, platform, geographical position, scan type, minimum and maximum frequency, minimum and maximum PRF, mean pulse width, mean bearing, scan period, amplitude level, frequency agility indication, pulse jitter indication). Rapids is controlled by soft keys (on the display) and by a light pen.

In 1984 Signaal credited the version using the DESM antenna with a sensitivity of 60 dBm at 2–7.5 GHz, and 55 dBm at 7.5–18 GHz, and with a bearing accuracy (in free space) of 3 deg. It could track 10 signals, lock onto 3 of them, and had a threat-warning capacity of 6 signals. Library capacity was 256 complex radars and 64 platforms. These capacities could be extended.

Like Sphinx, Rapids was transferred to MEL.

NORWAY

◆ SR-1A

This shipboard radar-intercept receiver (2.5–18 GHz) was made by Nera A/S. The antenna consists of a rotating antenna in a radome and a fixed octagonal horn array. The spinning antenna gives a bearing accuracy of 3.5 deg, compared with 22.5 deg for the omnidirectional horns at the base. The system as a whole can measure PRF between 200 Hz and 10 kHz, and pulse widths between 0.2 and 10 microsec. The spinner can rotate at up to 500 rpm, the speed varying automatically to avoid synchronizing rotation with that of the transmitting antenna (and thus losing all signals). The display is a CRT, showing a deflection pattern of multiple radial lines corresponding to the rotation of the spinner; the longest lines give the direction of the emitter, and these data can be read off as either relative or true bearing.

This system dates at least from the mid-1970s. This is the system originally on board German Type 143/143A/143B-class fast attack boats; it is being replaced by FL1800 (antennas grouped under the WM27 "egg" replace a masthead radome). The earlier Type 148s had the French DR 2000 at their mastheads. This system equipped Norwegian *Oslo*-class frigates, but it has presumably been removed upon their modernization. Nera A/S abandoned production of EW equipment in 1979.

◆ NE-10A

The Nera A/S broad-band submarine warning receiver operates between 2.5 and 11 GHz (usable up to 18 GHz). It covers the entire hemisphere over the antenna, and PRFs of 0.1–10 kHz. The system does not discriminate among signals: it emits its audible warning when it receives any pulsed radar signal over its bandwidth.

This system dates at least from the mid-1970s.

◆ VR-1B/C

Nera's submarine (VR-1B) and small-craft (VR-1C) RWR uses 2 tiers, each of 8 horns (with separate horns for vertical and horizontal polarization), to cover 2.5–18 GHz in 2 bands (E-lower J and upper J). Measurable PRFs are 200 Hz–10 kHz, and measurable pulse widths are 0.15–10 microsec. Bearing accuracy is 22.5 deg. Each horn has its own crystal video detector. The dual-beam CRT uses a logarithmic time scale to display the entire range of PRF and pulse width without changing scales.

The Dutch frigate *Van Kinsbergen* shows a Sphinx DF array around her foremast, under the egg-shaped radome of her Signaal WM25. The mast above carries the characteristic triplet of omni antennas for the system's IFM: 1 large cylinder (foreground), 1 small cylinder with a cone above (on the yard facing away from the viewer), and (on the yard facing forward) 1 small cylinder with a smaller 1 below it. The surface-search radar is ZW-08. (L. van Ginderen)

◆ VS-30

Nera's radar search receiver, ca. 1976, uses fixed wide-open ports to cover the 2.5–18 GHz range, with instantaneous measurement of PRF, pulse width, and bearing. There are 5 versions, with 3 types of antennas and 4 display and output arrangements. A typical unit consists of 3 tiers of horns, 8 per tier, alternating horizontal and vertical polarization.

SPAIN

There is now a national naval EW program. The navy's research center (CIDA) is developing the first entirely indigenous integrated ESM/ECM system, Aldebaran. It is less sophisticated than the Italian Nettuno of the frigates and the carrier and is intended for smaller ships such as the new EEZ-patrol vessels. The first trials units were delivered in 1989, and first production deliveries are expected in 1992. Aldebaran is associated with the Altair IR warning system being developed to control point-defense weapons, such as Meroka.

Four other systems are under development:

Canopus, under development by Inisel, is to replace the ELT/311 and /511 noise and deception jammers of the *Descubierta* class.

Deneb, under development by ENSA, part of the Ceselsa group, is to replace the passive parts (ELT/114 and /116) of the Gamma system of the *Descubierta* class. *Deneb* is also to be installed on board the *Baleares*-class frigates now being modernized.

Elnath is a communications countermeasures system.

Kochab is a decoy-launcher controller, developed by Inisel, to be installed on board the older frigates under the Tritan modernization program.

Inisel and Ceselsa initially agreed to split EW work, with Inisel responsible for the active elements and Ceselsa for the passive ones. This agreement lapsed in 1989, and Inisel is currently developing passive systems for submarines and small surface craft.

A special center for EW simulation has been set up at Rota.

About 1976 the Spanish navy installed a strategic ELINT system on board the fast attack vessel *Alsedo*, which typically patrols southern Mediterranean waters near the Straits of Gibraltar and off the North African coast.

◆ ENSA COMINT System

This system, suitable for naval, air, or ground use, is being marketed by ENSA, a division of the Ceselsa group. It has 7 elements:

- A fast interception receiver (EN/TSR-600) scanning at 640 MHz/sec over the 20–500 MHz range (expandable to 1200 MHz), with a resolution of 5 kHz, a sensitivity of –107 dBm, and a 120-dB dynamic range.
- An interferometric direction-finder (EN/TSD-530) accurate to within 2 deg.
- A classifier (EN/TRX-800).
- A monitor receiver (EN/TRR-400) that measures signal parameters (AM, FM, SSB, and CW signals).
- An exciter/jammer (EN/TLQ-700) operating over the 100–500-MHz range (expandable to 20–500 or 100–1200 MHz) and producing 1.1 kW of ERP. Jamming techniques are: single channel, barrier, multiple multiplexed channels, and responsive.
- An operator's console (EN/SRY-1000) with a high-resolution (1280 × 1024 pixel), 20-in color monitor, a keyboard, and a trackball.
- A processor (EN/TYK-610) using a 68020 chip, with 5 Mbytes of memory.

ENSA claims 100% probability of detection for emissions lasting 0.75 sec; its system can track up to 200 signals. They are correlated by time-frequency-direction, and post-processing analysis uses artificial-intelligence techniques.

SWEDEN

◆ EWS 905

Saab-Scania's dual-mode ESM/warning system identifies targets detected by search radar; this system is found on board Swedish fast attack craft (*Stockholm* and *Hugin* classes). EWS 905 automatically commands shipboard chaff launchers and other self-defense measures. The display shows bearing, frequency band, pulse interval, pulse width, and scan time, as well as the major evaluated threats. Up to 50 emitters evaluated as less threatening are stored and can be called up. There are 3 operating modes: alert (all bands covered, with the system concentrating on a single threat sector; the sector and frequency are displayed); decision (the antenna rapidly scanning a selected sector; bearing, band, pulse interval, and pulse width are displayed); and surveillance (the antenna slowly scanning the selected sector; the above parameters plus the target antenna's rotation rate are displayed).

EWS 905 masthead array. (Saab)

◆ 9CM and 9EW Series

PEAB's EW systems are intended for integration with the 9LV-series of FCSs. The chaff launcher is Philax, either in fixed (4-magazine) or trainable (8-magazine) form. Each 9CM system consists of a radar warner, a computer processor, and the associated chaff launcher: Matilda for 9CM100 (in the *Spica* class); Rapids, Phoenix II, or Cutlass in 9CM200. Computer inputs are warning data plus ship's heading, speed, and roll angle; ship's radar cross section and IR signature; and wind direction.

9CM100 (2 sets) and 9M200 (4 sets) use the fixed 4-magazine launcher.

The new 9CM300 will equip the *Goteborg* class. It employs a new 8-magazine trainable chaff launcher and a new ESM system (ARGOS Carol) using new lens and omnidirectional antennas and laser warning receivers. In the *Goteborg* class, the Luneberg lens antennas are mounted on the fore and after surfaces of the mast, just below the search radar. The lens antennas are used for both ESM and jamming.

There is also a new medium-range chaff rocket in fixed launchers for distraction. Systems incorporating this rocket are denoted 9CM150, 9CM250, and 9CM350.

The system was initially announced in 1987 as 9EW300, the

The trainable launcher of the 9CM300 system; this one carries 7 chaff magazines and 1 IR-flare launcher; it can fire 36 chaff salvos and 3 IR salvos (Saab)

corresponding 9EW400 being intended for small frigates. These systems do not include the active ECM system of the corresponding 9CM systems, and they may also use different ESM devices. Finland uses 9EW300 in her *Helsinki II*-class fast attack boats.

Philax, the PEAB chaff system, is rather larger than that associated with the Saab EWS 900CA. There are 2 versions, Philax 105 and 106, the latter carrying IR decoys. Small ships carry 2 launchers, larger ones 4. Each launcher carries a series of magazines, each magazine carrying groups of 40-mm chaff grenades that are fired together by a single ejection charge. In the seduction mode, the 9 grenades of 1 group form a 1000-m² chaff decoy about 2 sec after firing (about 20 m from the launch point, at a height of 50 m) and remain effective for about 20 sec. In the distraction (-50) mode, grenade flight time is 4 sec, and cloud cross section is typically greater than 300 m².

Each magazine holds 4 groups of grenades, a total of 36 grenades; it weighs 40 kg. Each grenade weighs 0.37 kg and carries 0.175 kg of chaff.

A magazine can be replaced by 3 IR-flare containers (Philax 106 version), each holding 21 decoys. Deployment is much like that of the French DAGAIE system, but the decoys are not the same. The first 5 IR grenades form an initial decoy near the ship (about 10 m away), then 2 remaining groups of 8 each are fired on varying trajectories, with parachute descent, to merge with the chaff cloud about 10–15 m above the sea surface. Reaction time is 2 sec, and the IR target is 150 m long. The decoy lasts about 25 sec. The IR payload is 4.5 kg, and the decoy works in both the 3–5- and 8–14-micron bands.

There are 82 Philax installations in Swedish service, and another 24 (the first of which was ordered in 1978) on board Egyptian fast attack craft. During the Gulf War this system was reported on board merchant ships operating in the Gulf. See also the British MEL Protean, which is essentially the same device.

◆ Bofors Rockets

Chaff rockets (57 mm) can be fired from rails rigged to existing Bofors gun mounts, using the existing gun-control system. Rocket dimensions are 57 × 1385 mm (16.5 lb carrying 2–2.2 lb of chaff), with maximum velocity of 420 m/sec; range at 30-deg elevation is 1400–6000 m. Time to bloom is 30 sec, and the chaff cloud lasts at least 6 min, forming a radar target similar to that of a 2000–3000-ton ship.

There is also a long-range 103-mm rocket (payload 2.4 kg, range 10,000 m).

TAIWAN (ROC)

The current EW systems are designated in a new Chang Feng (Long Wind) series:

Chang Feng I Probably WD-2A. It is a threat-warning receiver for small or secondary units, such as fast attack craft, developed

during the 1980s by CSIST, and covering the E–J-bands. Six were made for the PF800-series frigates (former U.S. destroyer escorts), and at least 30 more for *Hai Ou*-type missile fast attack boats. The frigates mount WD-2A on a short mast just forward of the Sea Chapparral launcher. WD-2A may also equip the 2 PSMM Mk 5 fast gunboats. This warning receiver is used to trigger the AV 2 and SMOC-3 chaff-rocket systems. This designation may include the rockets controlled by WD-2A.

Chang Feng II CS/SLQ-2, the ESM/ECM system for Wu-Jinn I (modernized *Fletcher*)-class destroyers; 4 were made. This system is probably integrated with the CR-201 chaff launcher. This designation may include the CR-201 rocket controlled by SLQ-2.

Chang Feng III Current-generation destroyer EW system, designed by Hughes and produced by CSIST; at least 10 were manufactured, for modernized *Gearing*-class destroyers. This system was based on the Hughes MEWS (SLQ-31) and SLQ-17. It incorporates a separate radome, probably containing a spinner antenna, for precise location of emitters. Reportedly, *Chang Feng III* has not been entirely satisfactory, and the new frigates will carry a new system, *Chang Feng IV*.

Chang Feng IV This is probably the Raytheon Shield system. Raytheon claims that its Sidekick jammer (see the U.S. Navy SLQ-32 entry) was originally evolved to meet a Taiwanese navy requirement, and a photograph of its new Shield system looks very much like an SLQ-32 with a Sidekick. *Chang Feng IV* will equip the new *Perry*-class frigates.

Other systems are:

AV-2 Israeli-type chaff rockets, carried as a pair of twin launchers with a common control panel. The rockets are electrically fired and manually reloaded; they produce an 80-m² chaff cloud. About 1500 chaff/flare rockets were made. For details, see the Israeli section.

CS/CR-201 Decoy-rocket system, using four 16-tube 126-mm launchers, carried by all GOCN destroyers. This system was based on the abortive army Kung Feng IV bombardment launcher (40 barrels in two 4 × 5 packs) and was installed in the early through mid 1980s; at least 19 sets (4 launchers each) were made. A new launcher (12 × 2 barrels) similar in appearance to the U.S. RBOC was displayed in October 1989. CR-201 resembles the Italian 105-mm SCLAR system; as in that system, there are both long-range distraction rounds and short-range break-lock rapid-bloom rounds.

SMOC-3 Decoy (chaff and flare) launcher for frigates and large fast attack craft (PSMM Mk 5 type), a slightly modified AV-2,

A Taiwanese (ROC) destroyer, firing her Hsiung Feng I missile, shows a CR-201 trainable chaff rocket launcher in the foreground. (Fu S. Mei)

probably with quadruple tubes and a different display/control unit. It was developed by CSIST in the 1980s, and at least 8 were made.

Until recently the chief warning systems were the U.S. Navy WLR-1 and the ARGO 680/681, the latter equipping Wu-jin Mk 1 ships (and thus perhaps forming the basis for SLQ-2). Surviving WLR-1s have been modernized to cover the J-band, to deal with new PRC missiles with J-band seekers (such as C801 and FL-1).

USSR

◆ Amber Light

This ESM for Akula- (and presumably Sierra-) class submarines is carried with Stop Light.

◆ Bald Head

Bald Head is the ESM in Alfa-class submarines, integrated with the Snoop Head search radar.

◆ Bell Series (Bell Bash, Bell Clout, Bell Crown, Bell Nip, Bell Push, Bell Shroud, Bell Slam, Bell Squat, Bell Tap, Bell Thump)

These surface-ship ESM antennas, located in small radomes, are often associated with jammers. Visual identification is complicated by the Soviet practice of mounting several radomes as a single unit, e.g., with a small radome pointing down below a larger 1 to save space. When the 2 units are separated, they are

still given a single nickname. Similarly, the elements of Bell Shroud are now often mounted separately.

Presumably, the Bell-series antenna associated with each jammer provides coarse (intermediate-grade) target data; it may also be a look-through receiver. For example, each pair of Side Globes or quadrant of Rum Tub or Wine Flask has an associated Bell-series antenna nearby. Each group of jammers also has a somewhat larger associated Bell-series antenna, which is probably the initial signal receiver for the ship's ECM system.

Typically, the 2 pairs of Side Globes on each side of a ship are associated with 2 different Bell-series radomes, Bell Slam and Bell Tap. These antennas antedate the Side Globe series; they were associated with the earlier Top Hat jammers in the Kynda and Kanin classes (1 for each pair of 2 Top Hats).

Bell Bash is associated with Bell Thump, in analogy to the combination of Bell Slam and Bell Tap. The associated jammers are Wine Flask and Wine Glass. The main external difference seems to be that Wine Flask is always mounted in a group of 4, whereas Wine Glass is to be found in pairs (e.g., in the *Udaloy* class).

Bell Clout is apparently the current initial large-ship signal receiver, replacing the earlier Watch Dog. It provides very coarse

The combination of a large radome (visible on each side of the tower foremast of the cruiser *Marshal Ustinov*) and the small radome under the yardarm is probably Bell Push. The conical antennas on the top of the bridge are sometimes identified as Pert Spring (for satellite navigation, as in submarines), and the small radome just visible on the right-hand side of the picture is Shot Dome (communications). In this ship, Bell Nip apparently replaces the earlier Bell Slam/Bell Tap combination. (S. Zaloga)

The *Sovremennyy*-class destroyer *Boevoy* shows a Wine Glass jammer with, below it, the 2 components of Bell Shroud. In most ships the small radome, with its bulb, is mounted above the large shroud. (S. Zaloga)

Bell Shroud on board the *Udaloy*-class destroyer *Admiral Vinogradov*, 1990. (S. Zaloga)

The cruiser *Kirov* displays her Side Globe jammers and a variety of Bell-series radomes in this 1981 photograph. The large radomes near the Side Globes and Rum Tubs are probably Bell Slam and Bell Tap; the small radome between the 2 Rum Tubs is probably Bell Push. Above it is Bell Crown, a communications antenna. The radar is Top Pair, and the 2 large flat radomes are Round Houses for tactical air navigation, analogous to the U.S. TACAN. The small radar above Bell Crown is Palm Frond. (U.S. Navy)

Bell Squat on the yard of the *Udaloy*-class missile destroyer *Admiral Vinogradov*, 1990. (S. Zaloga)

A heavily shrouded radome, apparently an auxiliary Bell Squat, on an outrigger on the foremast of the destroyer *Admiral Vinogradov*, 1990. The shielding testifies to considerable electromagnetic interference from shipboard radars and communications gear, such as the Round House tactical-air-navigation antenna in the upper right-hand corner of the photograph. (S. Zaloga)

data, and an intermediate receiver/tracker is interposed between it and the fine tracker associated directly with the jammer. This is an EW equivalent of what was once standard radar practice in many navies, i.e., the use of a broad-beam air-search radar to cue a target-indication radar, which in turn cued a target tracker. The target indicator (equivalent to Bell Clout, in this case) was a TWS device, whereas the target tracker was dedicated to a single target and provided much more precise data.

Bell Push appears to be the successor to Bell Clout, in the *Kirov* and *Slava* classes. Presumably, it has a wider frequency range since it is associated with the combination of Side Globes and Rum Tub.

Bell Nip is associated with the Rum Tub jammer. A pair of these conical radomes (of 2 different sizes) is associated with each pair of Rum Tubs on board a *Slava*-class cruiser.

Bell Shroud is the large radome just forward of the bridge in Krivak-class frigates. Its size suggests that it is the replacement for the earlier Watch Dog. Destroyers and frigates carry 2 Bell Shroud and 2 of the much flatter Bell Squat (on yardarms), a suite introduced about 1970 (for Krivaks, modernized Kashins, and *Udaloy*s). These ships lack any associated jammer; the receivers may be used to trigger chaff firing. Bell Shroud is recognizable by its tapered shape and by the knob (presumably a secondary radome) on its top. The shape of Bell Squat suggests that it is a monopulse DF array.

Bell Crown is a communications antenna.

◆ Brick Group (Brick Spit and Brick Pulp)

These passive threat-intercept and -warning systems for submarines were delivered from the late 1960s on, beginning with Victor and Charlie. Many submarines have only Brick Pulp. In Delta-I/II, Brick Pulp is supplemented by Squid Head. In contrast to Stop Lights, this group have radome-enclosed antennas. They are, therefore, probably U.S.-style rapidly spinning antennas rather than British-style wide-open DF systems. The advantage of the rapid spinner is that it has very high gain, so it can detect an airplane at a great distance, though it may well miss an intermittent transmission. The long-range detection would seem the more likely option for a submarine because an approaching airplane will use its search radar almost continuously.

Brick Pulp (2) on board a Victor-class submarine. The other visible masts are: (1) the Snoop Tray radar, (3) the VHF antenna, (4) the VHF antenna, and (5) the search periscope. This type of submarine has a total of 9 masts, the others carrying Pert Spring (navigation) and Park Lamp (VLF/LF reception), an attack periscope, and a snorkel. (*Sea Power*)

◆ Rim Hat

This ESM system is integrated with the Snoop Pair submarine search radar.

◆ Rum Tub

Rum Tub is a set of 4 radomes, divided into quadrants; each is split horizontally into a wider base and a narrower top, and each segment is further split into segments (5 at the base, 6 at the top), each segment showing 2 square plates, 1 atop the other. The appearance is quite unlike that of earlier Soviet radomes and may indicate some form of electronic scanning, like the lens operation of the U.S. SLQ-32. Each quadrant of Rum Tub is associated with a Bell-series radome. This association strongly suggests that Rum Tub is a jammer, covering a higher frequency band than Side Globe. If that is the case, then it may use some form of electronic scanning to track rapidly maneuvering antiship missiles such as Harpoon. However, Wine Flask, which replaced both Side Globes and Rum Tub, shows no signs of electronic scanning.

Rum Tub supplements the Side Globe series in large ships; it was initially installed on board the *Kiev*-class carriers and the cruiser *Kirov*, the *Slava* class, and then on board the modernized cruiser *Kerch*. Thus it first appeared about 1974 and was presumably developed sometime in the mid-1960s. Its origins, then, would coincide with the appearance in service of Ku-band aircraft radars (e.g., on the A-6 Intruder). It probably also covers at least some missile-seeker frequencies.

◆ Side Globe

Side Globe is reportedly a broad-band jammer. It consists of vertical pairs of radomes, invariably 2 pairs on each side of a ship, on the side of a tower mast or mack. Each vertical pair is accompanied by a Bell-series radome. Side Globe was a standard Soviet heavy-ship system of the late 1960s and later, in the *Moskva*, *Kresta-I* and *-II*, *Kara*, and *Slava* classes, and in the large cruiser *Kirov*. This system replaced the earlier Top Hat.

Side Globes and Rum Tub radomes on board the missile cruiser *Marshal Ustinov* at Norfolk, 1989. The 2 conical radomes between the Rum Tub quadrants are Bell Nips; presumably, they are analogous to the Bell-series radomes associated with Side Globes (which in this ship are carried on the yardarm). The 2 waveguides entering the Rum Tub quadrant suggest 2 bands, which would correspond to the 2 Bell Nips. (S. Zaloga)

As in the Western RAMSES system, each pair probably consists of a target-tracker and a jammer. Two identical directional antennas are used, so the tracker can achieve sufficient precision in measuring target parameters. The identification of 2 distinct Bell-series radomes with the 2 pairs of Side Globes on each side of a ship suggests that the 2 pairs cover different frequency ranges. The sheer size of the Side Globe radome suggests a very high gain antenna, and reportedly Soviet jammers produce very high effective radiated power.

Side Globe appeared in 1967; it was, therefore, probably designed in the early 1960s, when the sole important threat to Soviet ships was Western aircraft; the system is, therefore, presumably designed to jam aircraft search radars. To do that it would have to operate at relatively long range (hence the need for very high power), in the S- and X-bands. In the early 1960s the U.S. Navy was just beginning to move toward Ku-band in attack-aircraft radars (such as APQ-126 and the A-6 sets). Comparison with Western jammers such as RAMSES, which have much smaller antennas, suggests that the system uses high effective radiated noise power instead of some more subtle deception mode, such as false-target generation.

In the *Kiev* and *Slava* classes and in the cruiser *Kirov* the usual Side Globe installation is supplemented by Rum Tub. Rum Tub was also installed when the cruiser *Kerch* was refitted in 1988 with her new main air-search radar.

In the *Slava*-class cruiser *Marshal Ustinov*, new conical radomes were mounted near the pairs of Side Globes. In Western ships such radomes usually protect broad-band omnidirectional antennas.

The Soviet name for Side Globes is Gorzuf (after a town in Asia); the associated Bell series (D/F and emitter identification) is Zaliv (Bay).

◆ Squid Head

This standard submarine ESM antenna replaces Stop Light in many units. It can be distinguished from Brick Pulp by its smaller overall size and by the array of spiral antennas at its lower edge.

Squid Head (1) ESM antenna on board a Tango-class submarine. Antenna (2) is Quad Loop, a radio DF (the very similar Park Lamp, which has more loops, is a VLF/LF receiver). (4) is a periscope, and (3) is an HF whip. (Sea Power)

◆ Stop Light

This submarine ESM array was introduced about 1957. It is installed in submarines of that vintage (Foxtrot, Golf, Hotel, Echo, November). The Soviet name is Machta. This system is roughly analogous to Watch Dog, but there is only a single (octagonal) radome with the 4 tiers of horns (8 horns per tier, or band). A radome on top presumably houses an S-band dipole; the horns cover the X-, C-, and S-bands (probably 2.5–10 GHz). DF accuracy is probably about 10 deg. This system was replaced by Brick Group in submarines completed from the late 1960s on (Tango, Charlie, Victor, Yankee).

◆ Top Hat A, B

The first Soviet naval jammers, Top Hat operated in a 500-MHz band around 9370 MHz, with an output (in the original version) of 150 W CW using noise-modulated AM. There was a directional antenna (4-deg beam, 24–28 dB gain). In a few cruisers

Stop Light B (the A version lacks the pimple, presumably for an IFM, at the top of the array) (2) on board a Foxtrot-class submarine. The other antennas are (1) the Snoop Tray search radar, (3) the VHF whip, and (4) the HF whip. (Sea Power)

and destroyers Top Hat replaced a radar. Top Hat first appeared about 1962. It was replaced by Side Globe.

In Modified *Skoryys*, the jammer was mounted on the centerline, and 2 shallow cylindrical radomes (which presumably contained the directional ESM antennas supporting the system) were mounted on the sides of the ship.

Presumably, the ideal arrangement was paired jammers and receivers, as in the later Side Globe. A *Skoryy* probably lacked the reserve of top weight that would have been required and had to make do with a single jammer, on the centerline. However, *Kynda*-class cruisers and *Kashins* had paired jammers and receivers, an arrangement equivalent to, and presumably leading to, that in the later Side Globe. Unlike the Side Globes, Top Hat used widely separated ECM receiver and transmitter radomes, and they were not always identical. Presumably, the Side Globe's configuration was chosen to avoid the parallax and antenna mismatch problems inherent in the earlier arrangement.

Top Hat can be recognized by its squared-off appearance, as contrasted with the rounded shape of a Bell-series radome.

Kiev-class carriers are sometimes credited with 4 Top Hat A and 4 Top Hat B radomes.

◆ Watch Dog

The first Soviet ESM system, Watch Dog was introduced about 1957 and is still in service. Watch Dog is apparently a wide-open system, its array consisting of a cylinder carrying 4 tiers of microwave horns (8 per tier). Typically a ship carries 1 array on each side, each backed by a reflector. Presumably, each horn is tuned to a fairly narrow band, for a combination of threat warning, direction finding, and identification, over a 1–12 MHz band. In a *Kotlin*, for example, Watch Dog is mounted on the radar platform on the foremast. This system was apparently enclosed in radomes in later ships.

Watch Dog ESM (inboard of yardarm) and the Top Hat jammer it controls (lower left), on board the Kashin-class missile destroyer *Strogii* at Massawa, 1972. (Royal Navy)

◆ Wine Flask

This is a new jammer replacing both Side Globes and Rum Tub. It first appeared in the cruiser *Frunze*, completed in 1984, and

The battlecruiser *Frunze* displays the generation of jammers and ESM antennas that replaces the Side Globe/Rum Tub series. The 4 large vertical radomes are Wine Flasks, originally called Footballs. The small adjacent radomes, painted light gray, are Bell Thumps and Bell Bashes. The single dark-colored radome is probably Bell Crown. The small white antenna on the yardarm is probably Shot Dome. (*Sea Power*)

also in the carrier *Novorossisk*. The 4 antennas on each side are paired horizontally and vertically, with 1 vertical pair at each corner of a tower mast. Each big vertical Wine Flask radome has a smaller Bell Thump associated with it. This device has also been called "Modified Football" in the past.

The radome is substantially smaller than Side Globe, so the enclosed antenna presumably has reduced gain. That would be acceptable if the jammer depended more on deception than on pure noise, and such a change would be a logical consequence of improving Soviet electronic sophistication. Because none of the radomes is very close together, it seems unlikely that the pairing represents tracker/jammer combinations. Rather, each radome probably is vertical to accommodate stacked trackers and jammers. The vertical pairing probably represents a division by frequency band (presumably, Wine Flask is a broader-band device than Side Globes/Rum Tub), and the horizontal pairing provides the ability to deal with multiple targets.

◆ Wine Glass

This device is carried on board *Sovremennyy*-class destroyers. *Sovremennyy* was completed with 4 Wine Glass jammers, but the more usual complement is 2, 1 on each side of the forward

Wine Glass is the large radome visible just atop the bridge wing of the *Sovremennyy*-class missile destroyer *Otlichnyy*. The squat radome below it appears to be the upper portion of Bell Shroud; the radome on the yardarm above is Bell Squat. Other ships of this class have only Bell Shroud and Bell Squat. (S. Zaloga)

Wine Glass (inboard) and (probably) Bell Crown (outboard) on the mainmast of the missile destroyer *Admiral Vinogradov*, 1990. (S. Zaloga)

superstructure. Wine Glass resembles Rum Tub in shape but is smaller and covers 180 rather than 90 deg. It is probably the successor to Bell Shroud and, therefore, most likely an ESM device (ultimately the successor to Watch Dog).

Later units of the *Udaloy* class (from *Simferopol* onward) have 2 new radomes, presumably ECM-related, at the base of their mainmasts.

◆ Communications Intercept Systems

Cage Pot Kiev, Moskva, Slava, Kara, Kresta II, Kresta I, Kynda, and Mod Kashin classes

Grid Crane VHF-UHF intercept: *Slava* class

Site Crane VHF intercept: *Kynda, Sovremennyy, Kashin, Nanuchka, Petya, Ivan Rogov, and Alligator* classes

Sprat Star VHF intercept antenna, consisting of 2 bent dipoles of different lengths, apparently in the same plane. It is standard on combatants down to patrol boat size.

Cage Pot (in pairs) and *Sprat Star* (in pairs) are also carried on board intelligence-gathering ships (AGIs). The AGIs also have numerous specialized ESM antennas: Fir Tree, Log Maze, Trawl Net, Twin Wheel, Wing Fold. Specialized DF antennas: Cross Loop A, High Ring C, Park Plinth.

EXPENDABLES

Twin-tube trainable or 16-tube fixed chaff launchers are mounted on board many ships. There is also a spherical floating radar decoy containing a corner reflector.

One *Krivak, Bodryy*, has ten 10-tube chaff launchers in place of the usual four 16-tube units. The new 10-tube chaff launcher has also appeared on *Udaloy*-class destroyers. Unlike the standard 2-tube unit, it does not reload automatically from below decks.

The Pacific Fleet's *Udaloy*-class destroyer that visited San Diego in 1990 had small drums (distraction decoys) located along her deck edges; they are probably Soviet equivalents to

Chaff launcher on board the cruiser *Kerch*, 1989. This is the standard Soviet unit for ships of large destroyer size and above, generally mounted aft. Many older ships, including cruisers, still lack chaff launchers. Smaller ships use non-reloading units with more barrels, e.g., 16-barrel launchers in *Parchim*- and *Grisha-V*-class light frigates, in *Pauk*-class corvettes, and in *Tarantul*-, *Nanuchka*-, and *Sarancha*-class attack boats. The chute visible to the left is used to drop duds over the side. (Eric Grove)

Rubber Duck (DLF/SLQ-49), i.e., inflatable floating radar reflectors. In contrast, the short-range chaff mortars are seduction decoys. The *Sovremennyy*-class destroyer that accompanied the *Udaloy* had no deck-edge drums, but that probably means only that the drums are new and have not yet reached all ships (they

Not all the radomes on board Soviet warships are related to EW. The white radome visible above the electro-optical device and the chaff launcher is Shot Dome, for communications. This photograph was taken on board the *Udaloy*-class destroyer *Admiral Vinogradov*, 1990. (S. Zaloga)

A new countermeasures device on board the *Udaloy*-class destroyer *Admiral Vinogradov*, July 1990. Its appearance, particularly the buttons, suggests that it is a laser-warning device, developed in response to U.S. deployment of laser-guided bombs and missiles. Examples were scattered over the upperworks of the ship. (S. Zaloga)

Two of the new 10-tube chaff launchers, 1 horizontal and the other nearly vertical, on board the *Udaloy*-class destroyer *Admiral Vinogradov*, July 1990. (S. Zaloga)

certainly are not on board all *Udaloy*s). These drums are not the standard inflatable rafts common to modern Soviet warships.

UNITED KINGDOM

◆ Royal Navy Decoy Outfits

Current systems are:

DLA 6-tube Sea Gnat decoy rocket launcher, each barrel elevated 30 deg; mounted in 2 sets on each side of a ship, 1 at 30- and 1 at 120-deg angle to the centerline. Initial fit for Type 22 frigates, replaced by *DLB*. This is essentially the U.S. Mk 36; the rocket is RE Mk 4.

DLB 8-tube Sea Gnat decoy rocket launcher, to be replaced by a new *DLJ*.

DLC Knebworth/Corvus 8-tube 3-in launcher, often with 50-mm flare launcher atop.

DLD U.S. Hycor Mk 137 6-tube launcher for U.S. SRBOC Mk 36; several configurations.

DLE Plessey Shield for RFA auxiliaries.

DLF Irvin "Rubber Duck" floating corner reflector; also in U.S. service (*DLF*-2 launches the successor "Replica" decoy).

ELECTRONIC SYSTEMS

◆ Type 668/669

These jammers, associated with the UA-8/9 ESM system, were introduced in the early 1960s. The third member of the family was Type 667 (Cooky), a high-powered spot noise jammer (covering a 20-MHz band in S-band, and a 40-MHz band in X-band, in each case with a trainable 30-deg beam). By 1958 trials of Type 667 had shown that it could screen a carrier to a range of about 30 nm in S-band, or 10 nm in X-band, or screen a destroyer to 5 nm in S-band (and completely in X-band). The hope was that Cooky would screen a task force within an area roughly comparable to surface-to-air missile range, forcing enemy missile bombers (the AS-1 was the principal threat at the time) to approach so closely that the defending missiles could shoot them down. Types 668 and 669 were probably more sophisticated versions of Cooky, to include C-band jamming and pulse repetition (which was not yet available to the Royal Navy in 1958). The figures for Type 667's performance probably approximate those to be expected of the later 668/669.

A Type 669 jammer on board a "County"-class missile destroyer (second series). Type 668 has 1 jamming unit (rather than 2) on each side, presumably sufficient to deal with 1 rather than 2 threats at a time. (R. Cheung)

◆ Type 670

Racal's jammer, code-named Heather, is intermediate between early systems such as 668/669 and the UAF-1 jammer. Racal has supplied 27 sets for Type 42 destroyers and *Leander* Batch 3 and Type 22 frigates.

Type 670 (in the radome) is visible just below the Type 1022 radar, HMS *Manchester*, Antwerp, May 1990. The material wrapped around the mainmast, at the same height as the big air-search radar, is intended to absorb its signals so as not to create misleading echoes. (L. van Gin-deren)

◆ Type 675 (Guardian)/ETW

Thorn EMI's low-cost intercept system replaces Type 670. The first contract was announced in 1983. Guardian is an intercept system and associated jammer for both area (i.e., anti-surveillance) and point defense. Area defense is by pulse or barrage noise jamming; point defense (against missiles that have already locked on) is by RGPO and amplitude pull-off. Guardian can deal with several simultaneous threats. It employs 2 stabilized antennas (port and starboard or fore and aft), each including a DF receiver and transmitting antennas. The jamming antennas are mechanically steered for full azimuth cover and for elevation cover up to 50 deg. Each antenna consists of a pair of boxes around a pedestal, each box bearing 2 oblong antennas, 1 over the other. Bearing and threat data are fed by the associated ESM system, searching its own library for appropriate jamming techniques. Guardian can also use its own DF receivers to operate autonomously, classifying incoming signals. Because it incorporates a separate receiver, Guardian can remain open to new threats while jamming existing hostile signals.

Guardian incorporates a Thorn-EMI channelized ESM receiver, Wavefinder, which that company also offers on a stand-alone basis. Wavefinder is a hybrid receiver: signals are initially

Containerized Type 675(2) on board a Type 42 destroyer; a similar jammer is mounted on the other side of the container. The right-hand antennas are the receivers, the left-hand antennas the jammers. Type 675 and the commercial Guardian lack the dish antenna in the center of the mounting. (Thorn-EMI)

HMS *Nottingham* shows 1 of her 2 Type 675(2) jammers atop the container abaft her uptakes, 1990. (E. J. Grove)

channelized to reduce the loads on the superheterodyne and IFM stages.

Type 42 destroyers are normally equipped with Type 670 jammers, but in the Gulf at least some (such as HMS *Nottingham*) were equipped with Type 675 instead, on a pair of raised platforms, port and starboard, between funnel and mainmast. They may not always have been radome-enclosed.

Type 675 has been ordered to equip Type 22 frigates, Type 42 destroyers, and the *Invincible*-class aircraft carriers. It became operational in 1987. Thorn-EMI developed Type 675 as a less expensive alternative to an ESM/jamming system, Millpost (ordered 1975). Millpost, which was enclosed in an inflatable radome, ran trials in 1981-82, but a requirement had already been issued for what became Type 675(2). Guardian is the commer-

Basic Type 675 (Guardian). (Thorn-EMI)

cial derivative. Compared to Type 675(2), Guardian lacks the dish between the pairs of oblong antennas.

A new Early Threat Warning (ETW) program is intended to provide the existing Type 675(2) jammer with its own threat warner so that it can respond to changes in target-radar mode. As of June 1989, a contract was expected sometime in the summer of that year. Bidders included MEL and Thorn-EMI (the manufacturer of Type 675).

◆ Type 695

This is to be the jammer for Type 23 Batch 2 frigates. As of early 1990, the staff requirement had not yet been completed. The contract will be let on a competitive basis, one bidding team being Elettronica/Plessey.

◆ CXA

CXA is a communications-band (LF to A-band) direction-finding and threat-warning receiver found on board British nuclear attack submarines; it is an AEG-Telefunken Telegon. In British service CXA is arranged so that it can be augmented as required for signals or communications intelligence.

◆ FH 4/5

The standard HF/DF was developed during World War II; the characteristic "bird cage" antenna is still very widely used.

A standard FH-series (in this case serving FH 12) HF/DF array at the foretop of a *Leander*-class frigate, 1988. Below the "bird cage" array are omnidirectional antennas and 4 antennas for DF, with omnidirectional antennas (for IFMs) on the crosstree below them. They serve UA-8/9. (A. Raven)

◆ UA-1/UA-4

UA-1 was the first postwar British S-band DF set, for surface ships, ca. 1956. The antenna consisted of 4 horns mounted

around a mast, other sets of 4 each being added later to cover the C- and X-bands. The receivers were crystal videos without RF amplification, and the display showed intercepted signals as radial lines showing direction. Direction finding was by amplitude comparison, and a loudspeaker gave the PRF as an audible note. Operators tried to recognize radars by the combination of FRF and timed scan rate (antenna rotation rate).

These systems were later upgraded by adding a pulse analyzer (outfit YAF), 68 of which were bought after tests aboard HMS *Ocelot* and HMS *Ulster* in April and May 1971. This improvement was also bought for Brazil, Chile, and the Netherlands (for the *van Speijk* class); in all, Thorn-EMI had manufactured 80 by the end of 1973.

UA-2 and UA-3 were related systems for radar-picket destroyers, and UA-4 was a submarine-mounted equivalent, used primarily for warning.

◆ UA-8/9/10 (Porker)

These older passive intercept systems were derived from the original MEL IFM system, Pendant, which appeared in the late 1950s. Coverage: UA-8, 2.5–4.1 GHz; UA-9, 7–11.5 GHz; UA-10, C-band (also reported that each covers a 500-MHz band, so it may be coarse-tuned over the whole band, with IFM over 500 MHz). UA-8/9/10 are analog systems, and the display is a polar plot of frequency against bearing. The digital successor to these systems is the MEL Susie (see below). Compared to UA-1/4, these sets use broader-band superheterodyne receivers of greater sensitivity. UA-8/9/10 also introduced facilities for isolating and analyzing specific signals, using a library of known signal characteristics to identify them. Finally, these sets introduced pulse blanking, so that they would not pick up pulses from the ship's own radars (which would have swamped the much weaker pulses from distant radars). UA-8/9/10 have 4-channel amplitude-comparison DF systems similar to those of UA-1/4.

UA-8/9 are typically mounted together on a masthead, with their arrays superimposed.

Like the roughly contemporary U.S. WLR-1, UA-8/9 required the operator to search through the spectrum, find signals, and classify them. Operating experience demonstrated the need for an automatic mode (Project Tonga), a requirement eventually met in UAA-1. Feasibility and definition studies were conducted in 1963–66, project definition was completed in March 1966, a design and development contract was let late in 1967, and the prototype appeared on board HMS *Grenville* (delivered September 1969, in service January 1970).

◆ UA-11/12

UA-11/12 are Racal ESM sets for British SSBNs and SSNs, respectively. The associated array normally surmounts the dedicated ESM mast. UA-11/12 is used for precision bearing- and frequency-measurement, but reportedly its operation is slower and requires much greater operator concentration than does a more recent set. UA-11/12 dates from the 1970s. These sets are being replaced by Outfits UAB and UAC.

◆ UA-13

This passive array (25–1400 MHz) on *Ariadne*, *Cleopatra*, and *Phoebe* consists of a conical D/F antenna at the masthead, with projecting dipole arrays.

◆ UA-15

Racal's add-on to existing Royal Navy ESM systems extends coverage to the 12–18-GHz band.

◆ UAA

See Abbey Hill below.

UA-13 array on board a British frigate at Portsmouth, 1988, with UA-8/9 arrays below it. (A. Raven)

◆ UAB/UAC

UAB/UAC are Racal ESM sets for British SSBNs and SSNs, respectively. UAC has been installed on board *Trafalgar* and *Swiftsure* classes since 1985 and will be on board the new *Upholders*. UAC-3 will be on board the new Trident missile submarines. In existing submarines, outfit UAB is being replaced by the Racal outfit UAP.

◆ UAF-1

The Type 23 ("Duke"-class) ESM suite by Racal is the first Royal Navy ESM system to employ color displays. The antenna is an 8-port array atop the foremast. The system looks up intercepted signals in its library, displaying signal identity, bearing, and threat significance in tabular form, plus raw data on a frequency-bearing display that can be overlaid with symbology. There is also a manual pulse analyzer for further analysis of specific intercepts. The first production sets were delivered in the fall of 1989, for installation on board Type 23 frigates. In collaboration with AEG, Racal proposed a modified UAF(1) for the abortive NATO frigate.

Although UAF(1) is being fitted to the new Type 23 frigates, it is no longer considered adequate in view of the large number of high-PRF emitters, such as point-defense systems. The Royal Navy has, therefore, requested a new higher-capability UAF(X) for Type 23 Batch 2 frigates; Racal, Marconi, Thorn-EMI, and Plessey submitted bids in February 1989. UAF(X) was to use an identical ship interface (antenna system and front-end receiver),

HMS *Trafalgar* shows her ESM search outfit (UAB) atop a telescopic mast. The other two masts are, fore to aft, the snorkel induction (air intake) and the diesel exhaust for her emergency diesel. Forward are a radar mast and two side-by-side periscopes, all retracted. This photograph probably dates from 1985; more recent ones show a much more elaborate ESM array, with at least four monopulse DF antennas (probably spirals) around the broad-band cone visible here, and a short dipole surmounting the cone. These two antenna systems may be part of UA-11/12, the simpler cone being the UAB antenna. (G. Arra via *Ships of the World*)

but would have better man-machine interface and better processing.

Racal is offering a UAF(1) modified to use its SADIE VLSI processor; the latter has already been chosen for Royal Navy EH-101 helicopters. The receiver would use filter banks to channelize incoming signals, scanning each channel separately.

Marconi is offering a developed version of its UAG (developed for auxiliaries). In this case signals are channelized by Bragg cells. An experimental Marconi 500-MHz Bragg cell broke incoming signals into 500 parallel frequency channels (each presumably 1 MHz wide, and each having its own detector).

Thorn-EMI is also offering a channelized receiver; it claims that it can achieve ELINT precision in such a device and that its channelized receiver can detect signals at least as well as a conventional wide-open device. Moreover, the company claims that channelization makes the signal-to-noise ratio in each channel so high that its system can detect the sidelobes of a radar and, thus, can detect a sector-scanning set even if the latter is not pointing at the receiver. Thorn-EMI also proposes signal analysis by parallel computer (transputer). The faster the analysis, the larger the library that the system can consult. The company's generic Wavefinder ESM system can accommodate a threat library 10-15 times as large as that employed by a conventional ESM system.

No details of the Plessey system have been made public.

UAF-1 array at the masthead of HMS Norfolk, with Type 996 radar above, May 1990. (A. Preston)

◆ UAG-1

UAG-1 is an ESM/chaff-triggering system for patrol craft up to fleet auxiliaries. The requirement for this system was issued about 1983. Marconi was chosen, and the first application will be the new *Fort*-class AOR; UAG may also be installed on board the new LPD, the aviation training ship, and the proposed aviation support ship. This system is based on Mentor (see below); Mentor A was tested on board an RFA in 1987.

The first UAG system was delivered for trials in February 1989. It employs an omnidirectional antenna and 6 DF antennas, covering the 2–18-GHz range. As installed on board the new underway replenishment ships (AOR), the DF antennas are mounted on the sides of the radar platform. Marconi, which developed UAG, claims that it is the only ESM system that can overlay a synthetic picture on raw video. The 2500 radar-mode library can be searched in 1 sec, compared to 26 sec for standard Royal Navy systems that list only 200 radar modes. The export versions of UAG are Mentor 1 and 2.

◆ UAH

UAH is *Oberon*'s ESM suite; see Manta below.

◆ UAJ

Racal's ESM suite for *Oberons* is a modified Porpoise. UAJ uses the same display and processor as the Cutlass surface-ship set.

◆ UAL

Churchill-class SSNs' suite is similar to UAH (and, therefore, to Manta). UAL will also probably be retrofitted in other British nuclear attack submarines.

◆ UAP

UAP is an ESM suite by Racal; see Sabre below. UAP was selected by the Royal Navy in 1987; it employs the SADIE processor. UAP has much in common with the UAF of Type 23 frigates and will equip British submarines; it underwent sea trials late in 1989. The UAP(1) version will equip most British submarines; UAP(2) is the existing UAC, updated and with new antennas added. UAP(3) is for Trident submarines. UAP will form the basis of the Racal bid for the integrated ESM of the new SSN 20 class. Racal offers an export version of UAP(1) as ISIDORA III.

UAP shares the SADIE processor and the high-definition VU1400C color display with UAF(1). It is unique among British submarine ESM systems in providing an on board training facility. A typical system has a 2-bay console with 2 CRTs, 1 typically showing bearing vs. frequency (in a B-scope format); a typical display shows a box indicating accuracy limits around a detected signal. The second screen is an alphanumeric tote. The operator communicates with the system via a main keyboard plus 4 smaller ones splayed out to its right.

◆ UAR

UAR is the ESM suite for royal fleet auxiliaries, such as the new *Fort*-class AOR.

◆ UAS-1

Continental Defence Electronics's microwave surveillance receiver (RX-740 series) operates at 1–18 GHz (extendable down to 100 MHz and up to 40 GHz). Frequency resolution is 10 kHz (100 Hz is available as an option). Dynamic range is 60 dB. The receiver can sweep continuously over a frequency range, or it can step between any 2 preselected frequencies and search over a preselected range (minimum 50 MHz up and down) around any set frequency. Up to 99 channel steps can be preselected, stored, viewed, and recalled. Scan time is selectable between 100 msec and 100 sec. The spectrum display width is variable from 1 MHz to 50 MHz in 8 steps.

Continental also manufactures an Adcock DF array, a double stack of 8 vertical dipoles (4 for 2–500 MHz and 4 for 500–1000 MHz).

◆ UAT

The choice of MEL's EW suite for Type 23 Batch 2 frigates was announced in April 1990. It is derived from Manta and incorporates transputers for parallel processing. The choice of MEL reportedly reflects dissatisfaction with the Cygnus/Cutlass combination (UAF) in Type 23 Batch 1 frigates, and the UAT contract may include some improvements to the existing Cutlass/Cygnus.

◆ Abbey Hill (UAA-1)

Abbey Hill is the ESM system developed by MEL for the Type 42 destroyer, then for Type 22 (and, later, Type 21) frigates. Abbey Hill is also being fitted to most earlier types. Frequency range is 1–18 GHz. UAA-1 is the passive reception and pulse-measuring portion of the system, using the MEL IFM. UAA-1 in turn was designed to work with a constant-beamwidth antenna with a direction-finding accuracy of better than 3½ deg, compared to 15 deg for other systems.

MEL IFMs operate between 0.7 and 18 GHz in a variety of ranges and can exploit pulses with durations as short as 0.05 microsec. There are 2 ranges: binary, for high integrity in dense signal environments, and quaternary, for less demanding situations.

The intercept and D/F antenna is a series of ports (radome-covered horns) typically mounted under the masthead radar antennas, and covering 4 bands (probably 8 per band). Frequency-measurement accuracy is reportedly 1.5 MHz, and bearing accuracy better than 3 deg.

In Abbey Hill, UAA-1 is combined with an EMI threat-identification system and, reportedly, with an EMI jammer code-

Abbey Hill (UAA-1) DF antennas under the platform of a Type 992Q radar antenna. The round objects on the small yardarm are presumably the associated omnidirectional antennas feeding the system's IFM. There are 4 tiers of DF antennas, corresponding to 4 bands. (A. Raven)

named Millpost. At least in the original form, Abbey Hill made a tentative identification of a received signal, but the system also provided raw data so that the operator could decide. In 1981 it was reported that the Royal Navy considered the signal environment in the North Atlantic too dense for anything but fully automatic operation and so was seeking an updated version of the threat-identification system.

As of 1989, existing UAA-1 systems were being upgraded to UAA-2 configuration to deal with denser pulse environments.

◆ Masthead Repeater (Bexley)

This countermeasure was introduced in the 1960s to provide protection against Styx and similar missiles, which steer in both altitude and bearing. The repeater pointed back toward the sea surface to provide a false target some distance from the ship, toward the incoming missile. This type of countermeasure is not effective against a sea-skimmer, which approaches at fixed altitude and has a radar that does not look down; but the repeater should be effective against diving missiles, such as AS-4/6.

◆ Cutlass

Cutlass is Decca's combined ESM/ECM suite for a very dense signal environment (up to 500,000 pps, as in the Middle East or Europe); Cutlass operates in the 2-18 GHz range, using 2 digital bearing and frequency discriminators (2-7.5 and 7.5-18 GHz). Signals are automatically compared with a 2000-radar library, and the results displayed in tabular form, with threats automatically ranked. The display can show up to 150 threats on 5 pages, and the 30 most important threats are displayed automatically. The display also shows the level of confidence to be applied to the identifications. Selected digital data can be sent to other systems (e.g., antiship-missile fire control). Signal analysis is by IFM, the ESM receiver operating on 2 channels (frequency and bearing). The bearing channel can be used for weapons direction. A typical installation, providing all-around coverage from the masthead, consists of an omnidirectional antenna (to provide an input to the IFM) and 6 ports for direction finding by amplitude comparison. Cutlass B1, which achieves much greater precision in direction, uses a 32-element array for phase-analysis direction finding (2-deg rather than 7-deg accu-

An Egyptian *Ramadan*-class missile patrol boat equipped with Cutlass ESM gear, visible clamped to her mast above the big radome of her Marconi S1810 radar. The masthead array is probably the AEG Telegon HF/DF. The Cygnus jammer has not yet been mounted aft. (Giorgio Arra)

racy). The more accurate direction-finder suffices to target antiship missiles such as Harpoon.

The small-ship version of Cutlass (currently Cutlass E) uses the same antenna as the earlier Racal RDL series. Cutlass B1 uses the Anaren DESM antenna, described below in the U.S. section. It is installed, for example, on board Danish *Willemoes*-class fast attack craft, Danish *Nils Juel*-class frigates, and later Turkish MEKO frigates. A modified version is going on board German S143-class fast attack boats.

Cutlass generally provides (a) bearings over the entire 2-18-GHz range, with preamplification over 4-18 GHz; (b) IFM over the whole range; (c) signal processing/library look-up; and (d) CW bearing and frequency measurement over 2-18 GHz. As of 1988, frequency and bearing accuracies of 5 MHz and 5 deg were being claimed, over the 0.6-18-GHz range.

Cutlass can incorporate its own responsive noise jammer, which can track the target and can provide either spot or barrage noise. Cutlass can also be integrated with chaff launchers and with self-defense weapons such as Sea Wolf. In a typical installation, Cutlass operates with a Cygnus directional jammer.

The system is modular so that it can fit ships ranging in size from fast attack craft to frigates. Cutlass entered production in 1979. As of 1985, over 40 Cutlass systems had been exported, and this figure had risen to nearly 100 as of early 1988.

Cutlass was adopted in modified form for the Type 23 frigates (as UAF-1). Porpoise is a modified version, as are Octopus and Type 242.

Users include Bahrain (Cutlass E in FPB 62-class fast attack boats), Denmark (*Nils Juel* and *Willemoes* classes), Egypt (*Ramadan* class), Germany (Octopus for S143 boats), Kenya ("Province" class), Kuwait (FPB 57 and TNC 45 classes), Nigeria (*Erin'mi* class), Oman (Type 242 in "Province" class), Qatar (Combattante-III class supplementing DR 2000), Turkey (later

MEKO frigates), UAE (FPB 62 and modified FPB 38 classes), and the United Kingdom (UAF-1 for the first 4 Type 23 frigates).

◆ Cygnus

Racal's ECM system uses a narrow-beam tracking jammer (1–18 GHz). Cygnus was designed specifically to operate with the Cutlass ESM system, operating over a variable bandwidth for spot or barrage jamming. Cygnus has 2 separate antennas but 1 transmitter, so the system can jam 2 targets on a time-shared basis at maximum power. The associated IFM tunes the jammer within microsec of the receipt of a pulse. Radiated power is reportedly over 300 kW, which suffices to counter aircraft-surveillance and missile-guidance radars.

In 1988 it was reported that the latest version operates over the 8–18-GHz band (300 kW minimum power, 480 kW in mid-band), with 1/deg tracking accuracy.

Available jamming techniques include RGPO and false-target generation. A next-generation derivative now in production (Cygnus 2) uses a customer-defined ECM response code to respond to threats in its library. It will cover the range from 7.5–18 GHz. Maximum ERP is 480 kW in the middle of its frequency range, and 300 kW on average.

The Cygnus jamming dish antenna is flanked on its top and left side by interferometers (made by Anaren, a U.S. company), which it uses for target tracking. Each interferometer is accurate to within 0.2 deg. However, each can also function in a coarser mode. Thus the jammer can accept data from an ESM set with 20-deg accuracy, then refine those data to sufficient accuracy for jamming. By using the 2 interferometers, the system avoids the need for a separate directional receiver. Moreover, by using a special mechanism to differentiate target main lobes from target sidelobes, it can avoid the need for a separate omnidirectional antenna. An associated IFM can measure the target frequency to within 2 MHz. Once a target has been acquired, the pair of interferometers can point the dish to within an accuracy of 1 deg (elevation and bearing).

Each interferometer consists of 3 arrays—coarse, medium, and fine. The coarse beam is 40 deg wide. Once a signal has

been acquired, error signals from the coarse array place the signal within 10 deg, which is the width of the medium "zoom" beam. This array in turn positions the platform until the target is within the FOV of the narrow beam (2.5 deg wide). Each array is split in half and lobe-switched to track the target. Anaren claims that its approach overcomes multipath effects over water, an effect proportional to antenna beamwidth.

Interferometer frequency coverage is 8–16 GHz, and minimum pulse width is 150 nanosec.

Cygnus production began in 1977. Egypt ordered it for the *Ramadan* class in 1978, Bahrain ordered it in 1984, and it was ordered for the British Type 23 in December 1985. Users are Bahrain (FPB 62- and TNC 45-class fast attack boats), Denmark (Stanflex 300 class), Egypt (*Ramadan* class), Kenya ("Province" class), Kuwait (FPB 57- and TNC 45-class fast attack boats), and U.A.E. (FPB 62 and modified FPB 38 classes).

◆ Guardian

See Type 675 above.

◆ Hermes

Hermes is Marconi's airborne, shipboard, or ground ESM system.

◆ Manta/Sceptre/UAH

Manta, an ESM system for submarines, was derived from MEL's Rapids and was announced in 1983. Manta covers the 2–18 GHz range, providing automatic detection, analysis, and identification, and can feed into a tactical data system. The operator can override the threat library if the system picks up an unassigned signal. The capacity of the threat library is 2000 modes, and the operator can add another 100. The system intercepts signals at elevations between –10 and +30 deg, with horizontal, vertical, and circular polarization; 50 nanosec–100 microsec pulse width, and 0.02–40.0 sec scan period. Bearing accuracy is about 2 deg, sufficient for torpedo fire.

In 1987 MEL announced that it was working with Philips to extend coverage into the Ka-band (27–39 GHz).

UAH, for the modernized *Oberons*, is a version of Manta.

Sceptre is a version for surface ships, announced in 1985. It employs a boom-mounted omnidirectional antenna and a pair of mast-mounted DF half-arrays, each carrying 3 sets of 3 antennas (for 3 bands). The typical display consists of 2 side-by-side CRTs, 1 showing frequency against bearing, the other a series of best fits to library data.

MEL is currently delivering its Sceptre XL system to the Royal Swedish Navy for the *Göteborg*-class corvettes. The system operates in 3 bands, the DF antennas for the bands being mounted in 2 mast boxes. Frequency range is 2–18 GHz. Elevation coverage is +30/–10 deg, and bearing accuracy is 4.5 deg (with 2 deg available as an option). Sensitivity is –64 dBm, and dynamic range is 60 dB. The system can handle PRFs between 100 Hz and 300 kHz, pulse widths between 50 nanosec and 100 microsec, and scan periods of 0.02–40 sec. It is intended to detect radars with simple or modulated pulses, using frequency and PRF agility. Maximum pulse density is 1 million pps. The associated threat library covers 2000 emitter modes, with 144 emitter modes selected for threat warning and an operator library of 100 emitter modes.

Sceptre XL is the most complex of a series of Sceptre ESM systems. Sceptre X covers the same frequency range but uses a simpler antenna (single arrays of horns and spiral in each direction), is limited to 6 deg bearing accuracy, cannot deal with complex pulses, and has a threat library containing 1000 emitter modes. Dynamic range is reduced to 40 dB, and sensitivity is –50 dBm. Sceptre O is a much simpler system employing a single masthead antenna array (for both omnidirectional reception and DF), achieving a DF accuracy of 10 deg. The threat library is limited to 144 emitters; dynamic range is 35 dB, and sensitivity is –40 dBm.

Sceptre O is for fast patrol craft.

In September 1990 it was announced that Sceptre XL had been

Cygnus jammer, with the 2 boxes of its Anaren tracking receiver above the dish and to the right. (Anaren)

chosen for the ANZAC frigate program (10 systems were ordered, with an option for 2 more). This system is being developed into the new Royal Navy UAT (see separate entry).

◆ Matilda

MEL's Microwave-Analysis Threat-Indication and Launch-Direction Equipment is a lightweight low-cost intercept system for patrol craft and was announced in 1981. The design targets were £70–75 thousand and a masthead weight of 5 kg (to be reduced to 3–3.5 kg). The antenna is designed to provide a broad vertical beam, to detect both sea-skimmers and steeply diving (but not vertical) missiles. Typical coverage is 7.5–18 GHz. Frequency resolution: 1.5 GHz. Pulse-width range: 0.1–6.4 microsec (resolution 0.2 microsec). Bearing resolution: 45 deg. Sensitivity is –30 dBm, and dynamic range is 40 dB. Antenna gain (7.5–18 GHz range) is 6–8 dB.

Besides automatic threat recognition, Matilda provides a synthesized-voice warning of the impending attack, as well as advice of correct evasive action, within 1 sec of detection. A lamp indicates the sector from which the threat is coming, and Matilda can be connected to trigger an ECM system.

The system is optimized against locked-on or tracking radars. It avoids false alarms by scanning the rate at which incoming signals arrive, initiating action only when (i) more than 250 pulses of similar bearing, pulse width, and amplitude arrive in less than 500 msec, or (ii) continuous CW has been received for more than 100 msec. These conditions do not apply to secondary threats such as TWS radars.

The antenna consists of 4 spiral antennas (to intercept signals of any polarization), arranged in 2 matching halves that are clamped around a mast, each a tube about 115 mm in diameter.

MEL conceived Matilda as the simplest possible small combatant ESM system; it concentrated on the main threat, the locked-on missile or fire-control radar. Instead of using a library, the system looks for the generic characteristics of such emitters: low rate of change of bearing, constant pulse width, relatively constant signal strength, frequency 7.5–16.5 GHz. An MEL study of a wide range of missile radars showed that these characteristics were indeed common to virtually all and, therefore, that a valid generic warner could be built. Given such simplicity, Matilda can provide an alert within 1 sec of signal detection, and against a subsonic threat it provides at least 30 sec of warning, sufficient for some evasion. MEL argued further that chaff was the best instant countermeasure, particularly when the threat could not be identified in detail. It developed the Protean chaff system specifically to work with Matilda.

The parent PEAB company marketed this ESM system as Matilde, but in a more elaborate form, allowing the operator to do some signal analysis. As in Matilda, 4 horns clamped to the masthead feed 4 RF channels. However, information is displayed on a 12-in CRT that can show either signal direction or alphanumeric signal data. Threat evaluation is automatic, probably on the same basis as in Matilda, and hostile threats are listed as Threat 1; all others are listed as Threat 2, and further classified by the operator. Matilde is used to trigger Philax grenades identical to Protean grenades. Matilde uses the ship's FCS computer.

As of 1985, 12 Matildas had been ordered by the Royal Navy, to be integrated with Wallop's Barricade-series chaff launchers. Matilda E, an uprated version, was installed on board British "Hunt"-class minesweepers before they were sent to the Persian Gulf in 1987. Matilda E had been tested on board HMS *Dumbarton Castle* in 1986. This version will also be part of the PEAB EW system of the Finnish *Helsinki 2*-class fast attack craft. Other announced Matilda users are Egypt (October-class attack boats), Finland (Matilda E in *Helsinki-II* class; total of 9 sets bought), and Kuwait (8 on order as backups for Cutlass, given Cutlass's unreliability). The British Matildas are cross-decked among minesweepers going to particularly hazardous areas. The Korean navy may also use Matilda since this RWR is associated with the Protean chaff system that Korea has bought in some quantity.

Matilda was conceived as a very low cost RWR for merchant ships operating in the Persian Gulf, on the theory that it would reduce loss rates sufficiently to cut insurance costs, paying for itself. It is not clear whether any units were sold to private ship owners. For insurance and other legal purposes, a merchant ship carrying chaff rockets (Protean) would be a warship, so any merchant-ship captain would be reluctant to admit the presence of such a system. There were, however, occasional reports of rockets launched by merchant ships in the Gulf. Matilda reportedly suffers from a high false-alarm rate. The preferred method of operation would be to use a more reliable ESM system to trigger Matilda; once Matilda had been turned on (to launch chaff), the ESM system could focus on other threats.

◆ Mentor

This family of shipboard ESM systems, by Marconi, was announced in 1985 and was designed for small craft such as hydrofoils and minesweepers. The installation consists of an omnidirectional antenna and 4, 6, or 8 DF antennas. The system can be extended to mm wavelengths. Its library contains 3000 emitter modes, and it can have up to 100 programmable threat-warning channels. The display shows emitters in tabular form (typically track number, identification, bearing, frequency, PRI, and pulse width) as well as automatic warning information.

Mentor is built around a special-purpose digital signal processor that transforms incoming video for library comparison.

Mentor 1 is a simple missile warner (7.5–18 GHz, 9-deg bearing accuracy, –45-dBm sensitivity). Mentor 2 is a surveillance system (1–18 GHz, 6-deg bearing accuracy with 1-deg accuracy optional, –65-dBm sensitivity). Coverage can be extended into the MMW range. The masthead unit consists of 3 omnidirectional antennas and 6 DF antennas, presumably to cover 3 bands. Mentor 3 is the target-acquisition version, with bearing accuracy improved to 1 deg. The 6 usual channels are supplemented by a special dish (fine DF) channel. Elevation coverage is +50/–10 deg. The system can handle up to 1 million pps, with PRFs of 100–330,000 pps and pulse widths of 50 nano-sec–100 microsec; it can detect scan periods between 0.1 and 99 sec, and it can track 200 emitters simultaneously. Radar types recognized are: pulse, frequency-agile, PRF agile, frequency and PRF hopping, CW and high duty cycle, and FM-chirped pulse compressed.

The standard omni antenna is either 170 × 450 mm (5 kg) or 610 × 1240 mm (16 kg); the DF antennas are 445 × 457 mm (50 kg) or 1800 × 710 mm (100 kg). The masthead unit weighs 89 kg, and the ESM office set and console add 220–245 kg and 312 kg, respectively.

Extended versions are available for surveillance and for target acquisition (for the use of OTH missiles). Comparative characteristics, which are presumably typical of ESM devices, follow:

	Warning	Surveillance	Acquisition
Range	6–8 GHz	1–2 GHz	0.5–40 GHz
Accuracy	9 deg	6 deg	1 deg
Channels	4	6	6 plus dish antenna
Sensitivity	–45 dBm	–65 dBm	–65 dBm
Dynamic Range	45 dB	55 dB	65 dB
Amplitude Resolution	1 dB	1 dB	1 dB
Parameters in Library	1000	3000	3000
Processing Time	1 sec	1 sec	1 sec

Three versions, Mentor A, B, and C, were announced about 1987; they are export variants of UAG (see above). Mentor A and B are described as inexpensive variants of Marconi aircraft systems, something between an RWR and a full ESM suite. Mentor A identifies threat radars by their PRFs. Bearing accuracy is 10 deg, and typical processing time is 1 sec; coverage is

E- to J-band, with C/D-band optional. The library contains 2500 radar modes and provides audio warning with visual highlights. Marconi claims an MTBF of over 2000 hr. The display is similar to that of an aircraft RWR, showing emitters as alphanumeric symbols at their approximate bearings, the color of the symbol indicating its character (friendly, neutral, hostile, or unknown). The same display includes a table of emitters, giving their tags (as used in the bearing display), bearings, PRFs, relative amplitudes, and estimated identities. An adjacent display shows which automated warnings have been set.

◆ MIR-2

MIR-2 is the MEL ESM system for aircraft and small ships, for the 600 MHz–18 GHz range. MIR-2 uses 6 antennas, flush or externally mounted. The display shows frequency band, bearing, and amplitude activity; the operator can strobe to obtain true bearing and PRF.

See also Orange Crop in the Strike/Surface Warfare section.

MIR-2 equips British "Isles"-class OPVs. Reportedly, although Orange Crop was effective on board helicopters, it was unsuccessful aboard the OPVs; late in 1990 the Royal Navy was reportedly seeking an alternative. This situation was probably analogous to the problem the United States had with ALR-66(V)6; perhaps a shipboard system, unlike an airborne type, suffers from confusing reflections off the sea surface.

◆ Octopus

Octopus is a new Racal system recently selected by the German navy to replace the Thomson-CSF DR-2000s on board its Type 148 fast attack boats. It consists of a Cutlass B1 ESM system, a Scorpion jammer, and an AEG threat library. The German navy has specified 2 antennas: a wide-beam (40 × 40 deg) horn for area defense and a steerable carbon-fiber dish for point defense. Scorpion provides 150-kW mid-band ERP (50-kW minimum) and can jam up to 16 threats.

◆ Porpoise (UAI)

Racal's automatic ESM equipment for submarines (2–18 GHz in 2 bands: 2–8 and 8–18 GHz) is based on Cutlass. Parameters measured are bearing, frequency, signal strength, pulse width, and time of reception. Porpoise has a 2000-signature library, corresponding to about 400 radars (operating in different modes); and the operator can feed in another 100. The display shows emitters in order of threat priority, either in graphic (track) or tabular form. The highest priority emitters trigger both audio and visual alarms. The tabular display can show 25 tracks at a time, 150 in all being stored. Priority is based not only on the character of the emitter, but also on a calculation of the submarine's probability of detection, given the level of radar reflection from the masts, including the snorkel, and the sea-state.

Racal designed the Porpoise's mast specifically for the German Type 209 submarine, the most widely exported type. That boat required a nonretracting telescoping design. The antenna head is made of titanium, with an omnidirectional antenna (for IFM) surmounting 2 rows of directional ports for the 2 bands (6 in each row, spirals for the low band and horns for the high band). Signals are amplified in the head proper before being transmitted into the hull of the submarine for analysis.

Porpoise 2 is an improved version (DF accuracy 3 rather than 5 or 6 deg).

◆ RCM

Racal's (originally Decca's) RCM-series jammers were introduced in 1975 to work with other Decca equipment, such as the RDL series. RCM-1, which operates with the RDL-2 series, covers the 8–10-GHz range (using a high power CW TWT). RCM-2 series has its own IFM receiver and can handle several targets; 2 bands (5–9 GHz and 9–16 GHz) are available. The installation consists of transmitting and receiving antennas covered by a radome (2 radomes on larger ships). If a particular ESM signal is chosen, the system sets a 100-MHz slot around

it, the receiver searching within the slot to find the target frequency very accurately. The antenna trains and elevates.

The RCM-3B jammer is an improved RCM-2 with a processor and an IFM. RCM-4B has additional modes, such as noise covered pulse, combination jamming, and much higher effective radiated power. The original jamming modes were RGPO in RCM-1, with conical-scan deception added in RCM-2. RCM-3B and -4B have a memory loop to cope with frequency-agile radars. They have a responsive noise mode, in which the IFM is used to fast-tune a local oscillator to the frequency of the incoming pulse.

The RCM-3 gate-stealing jammer is now being added to large British surface combatants. The Nigerian MEKO frigate is fitted with the RCM-2 jammer (and the RDL-2 intercept receiver).

◆ RDL

Decca's RDL-series ESM system is used primarily to detect the enemy's radar-controlled weapons systems. Work began in 1968, the system being intended for Third World navies needing something less expensive and less sophisticated than existing Western ECM systems. By 1980 over 100 were operational in over 30 navies.

RDL covers a fraction of the 1–18-GHz band, the particular range depending on the version selected. The typical output is bearing, frequency, automatic pulse analysis, and alarm. The antenna consists of 2 semicircular units that wrap around a mast (so that it need not be positioned at the masthead); more can be added to expand frequency coverage to match specific threats.

Versions:

RDL-1 is the basic system, covering 2–11.25 GHz and including the APA-1C automatic pulse analyzer.

RDL-2/3 intercept and DF arrays around the foremast of a Brazilian frigate, 1986. Each array is split to fit around the mast.

RDL-1BC, for fast patrol boats, provides frequency band, bearing, automatic pulse analysis, and warning.

RDL-1BCS is a submarine version of -1BC, with an antenna consisting of 16 separate encapsulated elements (rather than a single encapsulated array).

RDL-2 adds the frequency of a particular threat. **RDL-257** extends coverage to 1–18-GHz; **RDL-268** adds frequency measurement.

RDL-2ABC, for larger warships, adds frequency measurement, visual pulse analysis, and RF amplification of the signal in the analysis channel for greater range and more effective analysis. The antenna consists of that for **RDL-1BC** plus additional units.

RDL-2ABC 6AC 8AC covers the entire 1–18-GHz range, with FM and automatic pulse analysis.

RDL-4BCS is a semiautomatic threat-warning system for submarines, covering 2.5–20 GHz. It provides instantaneous bearing and frequency measurement.

RDL-5 and -6 add D-band capability.

RDL-7 and -8 extend coverage to band J8.

The basic display is an A-scope (signals appear as spikes along frequency coordinate, presumeably corresponding to a mechanically or electronically scanned superheterodyne receiver). The operator selects the sector to be scanned in frequency and can select either auto-stop (the receiver stops scanning when it finds a signal) or auto-pause; in either case, the signal's frequency is read off digitally. Optional additions include fine tuning for better frequency accuracy, and the suppression of up to 3 known frequencies to avoid concentrating on known or friendly signals. Pulse-analyzing versions add a dual-trace pulse display, showing either pulse width or PRF in 2 ranges.

RDL-1C is an automatic pulse analyzer that can be added to any member of the series. It provides automatic digital readout of pulse parameters, either of all received signals or of those selected from the directional antenna array. Parameters for up to 5 emitter modes can be entered by plug-in circuit cards; the reception of a corresponding signal triggers an alarm, such as a warning light.

RDL-1C is a signal-recognition unit (with a 500-emitter library) that can be added to the basic **RDL** system.

RDL series users are Argentina (MEKO 140 frigates and TNC 5 class), Brazil (*Niteroi* class), Brunei (Vosper-Thornycroft missile boats), Iran (*Damavand* and Mk 5 frigates), Nigeria (MEKO 60 frigate, *Combattante-III*B- and FPB 57-class fast attack boats), and U.A.E. (TNC 45 class). The basic **RDL** wraparound antenna is also used in the later *Cutlass*, so it is difficult to distinguish between the 2 systems. **RDL** may also equip the Peruvian ex-*Daring*-class destroyers. It is not clear how these relatively limited sales can be reconciled with the manufacturer's claims given above.

◆ RACAL COMINT System

Racal introduced a new shipboard COMINT system in 1989, based on the company's land-based equipment. Two alternative antennas are used: a single compact stack for 90–400 MHz and a stack of 2 separate antennas for 20–500 MHz. The simpler antenna covers civilian and military marine bands; the more complex includes land combat net radio frequencies as well as paramilitary bands. These systems now incorporate a computer-controlled Fast Acquisition Receiver System (FARS). Changes of variable operating parameters, such as changes in signal level and target-activity level, are preset, and FARS filters incoming signals, e.g., to provide a display of the most recent active signals or of newly acquired signals.

In land applications, FARS has 2 alternative modes, scan and stop. It can scan at 40 MHz/sec or it can address up to 250 selected (listed) frequency channels, at the rate of 160 channels/sec.

◆ Sabre/Sea Lion

Racal's ESM system (Sabre for surface ships, Sea Lion for submarines) employs the company's SADIE signal processor and 14-in color raster display, both of which are also used in UAP and in the airborne Orange Reaper. Sabre is a development of the earlier *Cutlass*, covering the 0.6–40-GHz band with selectable bearing accuracy of 2 or 8 deg.

Sabre has been selected for the Danish Stan Flex 300, and Sea Lion for Danish and Norwegian submarines. These systems reportedly appealed to the Danes because of very fine DF accuracy, allowing them to distinguish individual targets on a crowded coast. The Royal Danish Navy requires 2-deg bearing accuracy since it hopes to use the system to target Harpoon missiles. The processor is SADIE, and this version of the system covers the 0.5 to 18 GHz band.

◆ SADIE

Racal's Segregation, Association, De-interleaving and Identification Equipment processor, for ESM, has separate elements for pulse segregation; for known emitter monitoring; for new emitter analysis; and for ESM processor control. The segregator recognizes pulses from emitters already characterized and segregates those pulses from new ones. That segregation allows the system to concentrate on new signals so that the system can function in very dense environments. The segregator uses the maximum number of monopulse parameters, e.g., frequency, pulse width, bearing, modulation flags, expected time of arrival, and expected amplitude. The monitor receives these data, including emitter number and whole pulse record, accumulating pulse parameters for each emitter and deriving exponential averages for the key parameters. The analyzer de-interleaves and characterizes emitters.

A typical SADIE consists of a segregator, monitor, 3 analyzers, 2 processors, and an operator/machine interface, all connected by a VME bus.

The SADIE processor receives parameters from the segregator and derives exponential averages for the key variables. Peaks that do not come from main transmitter lobes are rejected. The rest are passed to the ECM control processor (ECP), which performs a full scan analysis on all monitored emitters, if required. The analyzer is implemented on cards based on 68020 chips.

As of 1989, Racal had developed a new VLSI circuit (EWAM, extended window-addressed memory) for segregation in denser pulse environments. EWAM stores a window of values for each parameter in a set of emitters and rapidly matches input data against them. It can handle missed pulses and new scan bursts, automatically processing pulse data with invalid parameter measurements. EWAM uses 2.5-micron CMOS technology, incorporates 27,000 gates, and can process 25 emitters at a rate of 500,000 pps; 8 chips are mounted on a board to handle 200 radars simultaneously.

◆ SARIE

EMI's Selective Automatic Radar Identification Equipment, manufactured for the Royal Navy and for NATO navies, complements existing ESM systems. SARIE is an automatic ESM library look-up device (operating time about 0.1 sec) that accepts video from a receiver and displays the results of analysis (PRF, pulse width, and scan period) in alphanumeric form together with an assessment of the confidence of the identification. The system can also accept data on frequency, frequency agility, modulation, and scan type as aids to identification and will indicate PRF jitter. SARIE II contains data on up to 1000 radars, presenting data in tabular form.

SARIE II measures PRF between 31 Hz and 19.5 kHz (accuracy 1 Hz up to 1 kHz, 100 Hz at 10 kHz); PRF jitter; pulse width between 0.1 and 99.9 microsec (in increments of 0.05 microsec); and scan period between 0.1 and 59 sec (in increments of 0.1 sec). The system can compare a set of parameters with up to 1000 radars in less than 350 msec. Radar parameters are entered into the library by magnetic tape.

SARIE I, in production 1973–79, was sold to the Royal Navy and to other NATO navies; about 75 copies were made. Production of SARIE II began in 1979, and many were exported. SARIE was developed as a private venture, beginning in April 1972; it ran trials (with UA-8/9) on board HMS *Achilles* in November 1972.

◆ Scorpion

Racal's wide-beam jammer is capable of dealing with 5 targets simultaneously (to be expanded to 8 in later versions) in the 7.5–18-GHz range, with up to 50 kW of radiated power. The dual beam (wide/narrow) antenna weighs less than 100 kg, and the jammer operates in continuous, burst, cover, conscan, and RGPO modes.

Scorpion B is a wide-beam jammer version for the 7.5–18-GHz range, being supplied to the German navy; it can be integrated with Cutlass. Scorpion also equips Omani "Province"-class FPBs (others of this type are equipped with Cygnus).

◆ Sea Saviour

Racal's RWR (8–18 GHz) is designed for small combatants such as minesweepers. It uses a 4-port antenna, measuring bearing by comparing signal amplitude at the different ports to achieve 45-deg accuracy. Elevation limits are +40/–5 deg. Reaction time is less than 1 sec. Warning is by both digital readout and audio alarm. This system can also be programmed to fire decoys from systems such as Barricade.

◆ SPRAT

Racal's threat-warning system (8–18 GHz), designed for submarines, is mounted on the periscope. Detected pulses pass via the periscope cabling to an indicator in the control room; that indicator in turn uses LEDs to show the signal level, and a loudspeaker gives a corresponding audio alarm.

◆ Susie

MEL's solid-state ESM system has a frequency range of 2–18 GHz. Data are displayed in alphanumeric form. Susie automatically correlates frequency band, pulse width, and bearing, and displays these data together with PRF and signal strength. The operator can arrange for automatic tracking of selected targets and for an automatic lock-on alarm (i.e., missile alarm). Bearing antennas have 8 ports, for high accuracy. There are 3 versions, for fast patrol craft, frigates, and large warships. Antenna weight is 154–300 kg, depending on the version.

Susie-1 is intended for small warships. It equips the Dutch-built Indonesian frigates and is connected to chaff launchers. Susie-1 also equips Turkish *Dogan*-class fast attack boats and the Colombian FS 1500-type frigates (with Scimitar jammer and ARGO Phoenix II). Reportedly, it was bought for Malaysian Spica-M-class boats, but it appears to have been replaced by Israeli equipment. Susie-1F (for medium-sized ships) is a redesigned Susie-1, providing accurate frequency measurement.

Susie-2 is intended for medium-sized ships. The main improvement is to display precise frequency rather than frequency band; coverage extends down to 1 GHz. A threat library can be added.

Susie-3 is more sensitive and more accurate. It is probably the system on board the Indonesian frigate *Hajar Dewantara*, built in Yugoslavia. The Korean navy may also have bought Susie.

Susie was designed so that it could be used to control a Scimitar jammer.

Susie-1's performance: sensitivity, 30 dBm in fine range, 40 dBm in coarse range. Dynamic range, 50 dB. Antenna gain, 5.5–7.5 dB. Accuracy, 3.5 deg in fine mode. Pulse width, 0.1–100 microsec. Pulse repetition interval, 10 microsec (PRF 100 kHz) to 10 msec (PRF 100 Hz). Display write time, 18 microsec. The system displays frequency band and pulse width/bearing. It can auto-track 7 signals; it can store 5 signals, on receipt of which it triggers a warning signal, and it can store 2 signals that it blanks out automatically (i.e., own-ship or friendly signals).

These figures typify the very limited capacity of contemporary systems. Bands: 2–4, 4–7.5, 7.5–12, and 12–18 GHz. Susie 1F adds accurate frequency measurement (5 MHz) and is more sensitive (frequency receiver 40–47 dBm, optionally 65 dBm, gain 1–3 dB; the bearing receiver is the same as that of Susie 1). MEL offered 4 alternative antennas for these systems: A1, with a total of 24 antenna modules (to cover the 4 bands); A2, designed to support a Signaal search/fire-control "egg" (as in the case of the Indonesian ships); B1, which could share a masthead with a large air-search radar antenna; and B2, which differed from B1 in that access to the ESM antenna modules was from outside. A1/A2 weighed about 170 kg, and B1/B2 weighed about 315 kg. These arrays differ visually from the Signaal antenna in that there are only 8 radomes, each containing the antennas for each frequency range (presumably the 2 higher frequency bands share a single antenna). Each radome has a curved upper edge and straight sides.

MEL describes Susie as descended from UAA-1, but the antenna design, which is similar to that used in Sphinx, more likely derives from Signaal. CANEWS was a parallel development of UAA-1.

◆ TOAD

Marconi's Towed Offboard Active Decoy was conceived during the tanker war in the Gulf, and several sales were reportedly canceled when the war ended in 1989. TOAD is interesting mainly as a *civilian* ECM device, an attempt to protect merchant ships against attack. Early in the Gulf War there were reports that ships were towing corner reflectors to attract radar-homing missiles, but apparently these devices either did not exist or else were ineffective. After all, even the best corner reflector is unlikely to have anything like the radar cross section of a 100,000-ton tanker. Nor is it clear whether reports of chaff launchers on ships were accurate.

The Marconi towed decoy (TOAD), on display at RNEE 1989: the jammer in the radome is powered by the 2 propellers, which turn as the small boat carrying the decoy is towed through the water. The boat hull carries the Vosper-Thornycroft logo. (Author)

TOAD should have done better because it used active ECM techniques. It is an unmanned boat, towed by a ship, carrying wind generators and a solar panel, with a radome on top. Marconi also offered it in a catamaran version. TOAD was designed to operate in X-band, searching over a 100-MHz range for a seeker signal. It could handle 1 threat at a time, using noise and some deceptive jamming techniques. Frequency accuracy was within 5 MHz.

• Type 242

Racal's integrated ESM/ECM system was announced in 1987 (the number is Racal's, not the Royal Navy's); 242 has already been ordered by the Sultan of Oman's navy. This system combines modified Cutlass and Scorpion in a single console, and Racal describes 242 as one-fifth the weight of its predecessors (as well as cheaper and more reliable). The jammer is driven by the frequency-measurement unit of the ESM system, and the ESM data processor feeds the jammer directly. The processor is the new SADIE (see also the entry for Sabre/Sea Lion), which can handle pulse densities greater than 1 million/sec. The Type 242 ESM suite is based on that of the Royal Navy's EH-101 helicopter, covering the 0.5–40-GHz range.

EXPENDABLES

► Barricade/Super Barricade/Stockade

Barricade, a lightweight chaff launcher made by Wallop Industries, fires spin-stabilized 57-mm rockets from a stacked series of 6 open frames (3 rockets/frame), which point in various directions at different elevation angles, to form a large chaff cloud. The lower 3 sets of tubes are angled at 60 deg to each other for full azimuth coverage by long-range Stockade rockets (range 100–2000 m). The upper 3 sets fire short-range Pallisade rockets to 60 m from the ship to form a large overhead decoy for centroid seduction. Typically 1 set of 110-kg launchers is fitted to each side of a ship. Decoys are both chaff and IR. The original rocket had a range of 2000 m and carried a pound of chaff; that rocket dispersed its load centrifugally, spinning at 9000 spins/sec. Control is by a microprocessor that chooses the appropriate mode (distraction, dump/RGPO, confusion, seduction/centroid) and that also provides a recommended course to steer.

In 1981 Wallop announced a new 500-m rocket.

Barricade Mk II is controlled by a microprocessor, which stores decoy-firing sequences corresponding to various tactics.

Super Barricade fires a larger rocket (a new spin-stabilized fin round) than Barricade, to cover a larger ship. It uses 4 sets of triple barrels, the lower 2 trained 90 deg away from the rest so that a pair of launchers covers all 4 quadrants. The upper 2 sets are preset to point along the same bearing, but at different elevation angles. The upper 2 sets fire short-range Super Pallisade rockets in centroid deception mode; the lower 2 fire medium- and long-range Super Stockade in dump, distraction, and confusion modes. An associated tactical computer stores firing sequences for alternative tactics.

Super Barricade development began in 1987, and in 1989 Finland ordered it for a new minelayer; Chile has also expressed interest.

Wallop displayed a new long-wavelength IR decoy rocket at NEE 1989, to counter thermal imaging systems, which are more difficult to deceive than the earlier scanning-seeker heads because they look for extended targets rather than particular hot spots. It ran Royal Navy and NATO trials in the fall of 1989. Wallop sees the new decoy as an alternative to Sea Gnat, which uses a floating flare and reportedly has had problems in rough water.

As of 1989, Wallop hoped to sell Super Barricade to the U.S. Navy, initially for the PHMs and then probably for mine-countermeasures ships. Compared to SRBOC, Super Barricade can achieve long range without any deck reaction (SRBOC is a mortar, so the deck reaction worsens as the required range increases). The system is also lighter than SRBOC.

Barricade chaff launcher. (A. Raven)

Stockade is a related lightweight chaff launcher for fast patrol boats. Unlike most chaff launchers, Stockade consists of frames, inside which are launch tubes containing 57-mm fin-stabilized rockets. The launcher itself weighs only 10 kg unloaded. Each assembly consists of 3 frames holding 9 rockets, pointed in 3 directions and elevated; together the rockets form a chaff cloud with a radar signature approximating that of a corvette. Typically, 1 launcher is mounted on either side of a ship.

The rockets burst at an altitude of 70 m, at ranges of 400–1500 m. The associated IR decoys ignite at 1000 or 1500 m and burn for 30 sec. As of 1980, longer-range (5000 m) and hotter IR decoys were under development.

Wallop also offers Stockade-Seafish: a remotely controlled boat launches the Stockade chaff rockets, usable at ranges as great as 20 km. The boat carries 2 decoy launchers (18 barrels).

As of 1988, 42 Barricade installations were on order, and 56 had been delivered (including 40 on order and 28 delivered to the Royal Navy). Unit price was then about \$625,000. Export users include Chile (*Prat* class), Denmark, Kenya (*Nyayo*), and Oman.

◆ Corvus

Plessey-Vickers's chaff-decoy rocket launcher consists of 8 tubes: 2 sets of 3 at right angles, and 1 set of 2, above, bisecting that angle; all tubes are at a fixed elevation of 30 deg. The usual pair of port and starboard launchers is considered sufficient to deal with 3 attacks. In 1979 a new Plessey BBC (broad-band chaff) round (101.6 × 1580 mm, 21.8 kg including a 6.8-kg payload) replaced the earlier Knebworth. At the time the BBC round carried the heaviest payload available in a rocket of its dimensions. Chaff is dispensed in 1 of 3 modes to cover the G–K bands; dispensing range is set by a fuze adjusted manually before launching. At a threat wavelength of 2.6 cm, 2.5 sec after bursting, the BBC rocket produces a 1200-m² radar target that, given the enhancement effect of echoes off the sea surface, is equivalent to a 12,000-m² ship's radar target.

There is also an associated IR decoy. One version, by Plessey, uses the chaff rocket as a buoy, with the IR flare on top.

A Corvus launcher, with its rocket flare (illumination) launcher on top.

The prototype 6-barrel launcher went to sea on board HMS *Arethusa* in 1968. This system was exported to the Dutch, Brazilian, French, and other navies.

Many standard Corvus 8-barreled launchers carry a single Attwell 2-in rocket-flare launcher atop them. This launcher is manually fired. There is also a single stand-alone rocket-flare launcher, manually trainable on its own pedestal.

◆ Offboard Active Decoy (Outfit DLH)

Bids for a Royal Navy offboard active decoy were submitted in February 1989 by Marconi, Thorn-EMI, and Racal. Thorn-EMI and GEC-Marconi were selected in June 1990 for project-definition studies, and deliveries should begin in 1992 (the decoy is expected to enter service in 1993). A feasibility study was completed in 1988. The device is to be fired from the standard 130-mm Sea Gnat (U.S. Mk 136) launcher. Reportedly, its role has not yet been defined. A long-range decoy might make do with a 100-W TWT and a frequency-memory loop, whereas a short-range decoy would need much more power to deny an incoming missile burn-through vision of the ship. Marconi has proposed a rocket, burning for about 1 sec to project itself well clear of the ship. After burn-out the decoy, based on Marconi's Siren, would descend by parachute. Marconi claims that Siren can acquire a threat signal in less than 1 sec. Racal uses a BAe glider (reportedly resembling an ultra-light aircraft) with flip-out wings; it claims that its novel and highly accurate receiver system, based on its shipboard equipment, will be effective against multiple simultaneous threats, and that inherent accuracy of positioning will ensure that the decoy does not seduce incoming missiles into other ships. In each case, ongoing efforts to reduce a ship's radar cross section are expected to reduce the load on the decoy.

DLH was the third element of the ARE's future air-defense program, with SDMS and VSRAD (described above).

See also Siren, below.

◆ Protean

Protean is a chaff system developed by MEL to work with the Matilda ESM warning system. The parent Swedish PEAB company markets it as Philax (see above). MEL considered a rapid-blooming chaff the best instant countermeasure to a missile attacking a small combatant such as a minesweeper; chaff can bloom in less than 5 sec to give an effective cross section of over 1000 m². In the case of Protean, a salvo of 9 grenades gives the desired 1000-m² cloud; each launcher can develop 16 such clouds before reloading. Each launcher contains 4 cells (36 grenades each); cells reload as units. Total reload time is less than 1 min. The grenades can be fired directly by Matilda or manually on receipt of a Matilda alert. They operate in seduction mode, fired into missile's bearing and range gate, while the target vessel maneuvers to keep the cloud between herself and the missile while she moves out of range.

The typical installation is 2 or 4 launchers, and 1 or more chaff magazines can be replaced with IR grenades. Time to deploy a grenade cloud is 5 sec; height is 40–60 m (flight time 1 sec). Grenades weigh 0.35 kg, and they can be made in several wavelengths.

Protean appeared in the late 1970s, and by 1980 it equipped several fast attack boats as well as the Nigerian Mk 9 corvettes.

Protean chaff launcher. (MEL)

◆ Replica (DLF-1/Rubber Duck/SLQ-49)

Replica is an inflatable buoyant structure that supports a fabric-backed octahedral corner reflector; Replica operates as a distraction/seduction decoy. To a radar, the result looks very much like a ship. Replica, a substantial physical structure, is inherently broad-band, unlike chaff, and is considered effective for up to 3 hr in sea-state 4. The standard decoy is carried in two 1.14-m-long containers, similar to those used for life rafts, on inclined ramps. When the containers are released (either man-

Irwin Replica radar decoy, stowed (left) and deployed (right). (Ships of the World)

ally or automatically), they begin to inflate before hitting the water. The 2 decoys remain connected by a 4–5-m line, and the end of 1 of the 2 containers remains connected as a drag anchor, to keep the line taut (and thus to prevent the 2 decoys from collapsing together). Each decoy is about 2.5 m from apex to apex. Inside, the decoy has silver-coated nylon mesh suspended from aluminum-alloy tubes. Replica can be set to self-destruct or can be activated by remote control.

Rubber Duck was developed as a consequence of Falklands War experience. Reportedly, it was inspired by a Soviet decoy, which is similar but spherical (about 2.5 m in diameter). DLF-2 is an improved version (with a larger radar cross section). Reported export customers are Saudi Arabia and Thailand. Proposed fitting to British warships has been reduced because of budget cuts. The Royal Navy calls DLF Rubber Duck.

This decoy has been adopted by the U.S. Navy as SLQ-49. In April 1987 the U.S. Navy reportedly tested an air-launched version of Replica, comparable in size and shape to a Mk 46 torpedo. At that time the navy was also testing an improved version of the basic SLQ-49.

♦ Seafan

Vickers-Plessey's 105-mm decoy rocket launcher, for small craft such as fast attack boats, was originally conceived as a smaller equivalent to Corvus, for rapid installation on board merchant ships that might have to operate unescorted (albeit in convoy) during a period of rapidly escalating prewar tension. Seafan employs a 200-kg (vs. 762-kg for Corvus) 6-rnd fixed launcher. As originally proposed, Seafan was to have been fired from a lightweight triple launcher, and it was claimed that an existing Corvus launcher could fire 15 Seafans.

In 1977 Plessey announced a new Seafan rocket to dispense broad-band chaff (105 mm $\times$ 979 mm, 17.26 kg, carrying 4.1 kg of chaff). Elevation was fixed at 25 deg so that the rocket would begin to seed the chaff cloud while still rising. The resulting triangular chaff cloud was expected to last longer than most. A 0.33-sec fuze setting would produce a cloud between 24 and 155 m from the ship, and between 10 and 61 m high. After 2.5 sec this cloud (from a triple launcher) would have a reflecting area of 2500 m², reaching 4100 m² in 10 sec and lasting about 3 min.

The key to reduced rocket size was a multinozzle motor using wraparound fins; Vickers claimed that Seafan would be considerably smaller than the existing Knebworth rocket. The advent of this rocket in turn led Plessey to develop the Shield broad-band decoy system, using the original Corvus tubes instead of smaller-diameter ones.

There is also an associated IR decoy, the Vickers Honeydew hot-spot round, which is a spar decoy. A hot spot is held above the water by the bulk of the rocket, which acts as a spar buoy. As long as the hot spot lasts, it has a considerably stronger IR signature than a ship and will, therefore, decoy an approaching missile.

♦ Shield

Plessey's broad-band chaff decoy system employs port/starboard sets of parallel- or crossed-barrel 6-tube launchers and variable-range rockets to distract or seduce incoming weapons (seduction is by moving the target's centroid). Chaff can be deployed at ranges from 35 to 2000 m, each 4-in (102-mm) broad-band chaff (BBC) rocket carrying about 6.5 kg. Variable chaff range is obtained by setting a time fuze (0.5–12 sec) that ignites a secondary gas generator in the nose, unlocking the nose and spraying out the chaff packs. There is also an IR decoy, the rocket having a range of 40–160 m. Each carries 7 IR submunitions, to cover a large physical area in the 3–5- and 8–14-micron bands.

Each launcher carries two 3-rocket modules, either parallel or crossed at an 80-deg angle, and fixed in elevation at 30 deg. The launcher is strong enough to carry 3 modules so that in the crossed-launcher case the number of forward-aligned barrels can be doubled. Plessey recommends the crossed-barrel launcher for

corvettes or smaller vessels, and a pair of parallel-barrel launchers for larger ships.

Three different tactics can be used. In the distraction mode, up to 4 separate chaff clouds are deployed in a pattern around the ship, up to 2 km away, in hopes of attracting incoming missiles and diluting the incoming attack. The manufacturer states that only a rocket system can execute this tactic since no mortar can provide the necessary range. A second mode, dump decoy, is used in conjunction with an active ECM system such as Decca's Cutlass. The missile's range gate is distracted onto a chaff cloud about 400 m from the ship. Actual range depends upon ECM characteristics. For example, if the fuze is set at 2.5 sec, the burst will occur at 400 m at an altitude of 145 m; by 2.5 sec after burst, the chaff cloud will be ship-sized. Typically, such a chaff decoy is placed abaft and to 1 side of the real target. Finally, there is centroid seduction, a last-ditch defense. The chaff cloud is superimposed on the missile's image of the ship. Because the missile tends to home on the centroid of this image, and because the chaff cloud is more reflective than the ship itself, it may lock onto the cloud. The radar cross

Shield launcher. (U.S. Naval Institute)

Shield launcher being loaded. (Plessey)

section of the cloud is further increased by reflections off the sea surface because of multipath propagation. If the fuze is set at 1.5 sec or less, the cloud can extend between 90 m and 395 m in range, and between 25 and 138 m in height. The reflecting area 2.5 sec after burst is 3000 ft², expanding to 5500 m² 10 sec after burst; the cloud remains in place for up to 5 min.

Shield is designated DLB (DLE when adapted to royal fleet auxiliaries). The basic launcher is sometimes used to fire IR decoys as well as chaff rockets. Plessey offers a containerized version, incorporating two 6-barrel launchers, to protect merchant ships. This version includes a 24-rnd ready-use locker but apparently not the associated ESM warning device.

Shield 2 is an automatic version for export; it has been adopted by Brazil, Canada, and 1 unidentified Southeast Asian customer. The Royal Navy's version is manual. The Canadian ships will fire P6 IR rounds (using the same pyrotechnic material as in the German Hot Dog), and P8 chaff rounds (adapted BBC, with a larger payload and a programmable electronic fuze). P5 is the broad-band chaff rocket, using a manually set fuze, in Royal Navy service. P5 was used in the Falklands War (20,000 rockets were deployed to the South Atlantic).

P6 is a mortar because long range is not needed; missiles will generally use their IR sensors for terminal homing. Each tube fires 7 submunitions to walk the IR sensor away from the target, the first at 50 and the last at 250 m. The recoil of each shot indicates that firing to the launcher, and dampers in back of the launcher cushion recoil to eliminate deck reaction. The entire decoy tube is removed and thrown away after firing. Decoys are available in both the 3–5- and 8–14-micron bands. P6 dimensions are 102 × 1630 mm (17 kg).

Each P8 round contains 7.5 kg of chaff and can be set to burst at any range between 50 m and 2.5 km. It is essentially P5 but with an electronically set fuze for remote automated operation. Decoy modes are seduction and distraction. Shield is, then, intermediate in range between Corvus and decoys (such as Sea Gnat) currently entering service. The Royal Navy places it aboard larger ships, with Barricade aboard smaller ones. Both will be reduced to a supporting role when Sea Gnat enters service. P8 dimensions are 102 × 1700 mm (19 kg).

Shield was developed as a private venture after the Falklands War. As of early 1989, at least 106 Shield installations were in service, and 74 more were on order. Unit price was about \$250,000, plus \$120,000 for radar-absorbent cladding, without which Plessey will not sell Shield. The system was first sold in 1983 for the Brazilian *Inhauma*. Shield 2 is an automatic version for export; it has been adopted by Brazil, Canada, and Singapore. The Royal Navy version is manually fired.

In conjunction with Shield, Plessey offers a system for computer simulation of chaff-firing scenarios. A massive series of computations, typically as many as 5 million, is used to determine a short list of optimum tactics. These in turn can be fed into the decoy system's memory, which is connected to the ship's tactical data system. When threat data are fed to the decoy controller, the appropriate tactics are looked up in the preset table (which can hold up to 8 threat types, and which is also fed with such variables as wind speed and direction, sea-state, and ship's course and speed). The table is carried in an EPROM computer card.

◆ SIBYL

British Aerospace/Thomson Brandt's joint venture was announced in 1982. It uses a combination of rocket chaff/IR decoys and off-board ship-controlled jamming. The launcher has 12 tubes (4 tubes for smaller craft), is trainable and elevatable (limits +80/–20 deg, with automatic loading at 90 deg), and is stabilized in 2 axes. There are 7 types of ammunition—floating active decoy (simulating a ship's radar, to seduce ARMs); remotely controlled off-board jammer; long-lifetime chaff decoy; combined IR/chaff decoy; "hot balloon" decoy carrying chaff; a radiation-absorbing decoy covering the spectrum from the visual to 14 microns; and a practice round—in 2 sizes, 170 mm and 263 mm. Effective range is 0 to 8.5 km.

Sibyl decoy rockets, with the combined chaff/IR round on the right. (British Aerospace)

◆ Siren

Marconi's expendable 130-mm (1.8 m long, 28 kg) active-decoy round was announced in 1985 as the world's first intelligent off-board ECM jammer. Siren is parachute-retarded and is intended to seduce incoming missiles. Typically it is fired in company with chaff and IR rounds, selected by a central processor. At a preset distance from the ship, Siren switches on its own receiver, transmitter, and control electronics, using the RGPO seduction technique. The decoy is fired to a position 400–500 m from the ship, and Siren takes more than 1 min to descend by parachute.

Siren development began in 1982. This is 1 alternative for the Royal Navy DLH active decoy (see above). In 1989 it was evaluated by the U.S. Navy under the Foreign Weapons Evaluation Program. Compared to the long-life Nulka, Siren is conceived as a last-ditch decoy.

Siren will be fired from triple or sextuple launchers, 2 for a small ship and 4 for a larger one.

◆ Warrant

Widney-Aish announced this new chaff and IR decoy system in July 1989. It is similar in concept to the Barricade and Stockade launchers, which Widney designed in 1978–79 and still manufactures, but with a new 76-mm spin-stabilized rocket made by Astra Holdings. Warrant incorporates the same course-to-steer technology as Barricade. It is intended for small surface combatants, up to 100 m long, and lies between the 57-mm Barricade and the larger Super Barricade.

There are 2 different rockets, 1 for confusion (range 2500 m, weight 4.6 kg) and 1 for distraction/dilution and short-range

Warrant. (Widney-Aish)

duction (range up to 800 m, weight 6 kg). Each launcher consists of 6 triple subunits, 3 upper ones, very close in bearing, for short-range rockets, and 3 lower ones (splayed out at different bearings) for medium/long-range rockets. There are also IR rockets.

A single control unit normally connects to 2 launchers, but it can accommodate up to 6 more.

UNITED STATES

ELECTRONIC SYSTEMS

◆ ALR-66(V)6

These General Instruments's ESM systems are on board the *Pegasus* and *Taurus*. (See the photo of *Taurus* in the Strike/Surface Warfare section, under the APS-137 radar. See that section for details of this equipment, originally designed for airborne use.) The antenna array is similar to that of Locator 1000, which is not the same system. Reportedly, ALR-66(V)6 has not proven satisfactory in service, and only the 2 ships currently fitted have it. Its replacement is the new SLEWS (see below).

◆ BRD-7

This radio direction-finder for submarines uses an antenna on the General-Purpose Periscope ECM antenna group; BRD-7 also contains an internal DF antenna. The DF antenna is typically mounted atop the snorkel air induction mast. BRD-7 may be connected to the periscope ECM antenna group.

◆ SLA-12

SLA-12 is the EW antenna group used with ULQ-6 and SLQ-22, -23, and -24. SLA-12 uses the AS-1751A/SLA-12 trainable-antenna group and the complementary AS-1750A fixed-antenna

group, 1 each of the latter being mounted above and below the trainable AS-1751A. A complete installation consists of sets of all 3 antennas located port and starboard. Although this system is no longer widely used in the U.S. Navy, SLA-12 was transferred to many friendly navies on board former U.S. destroyers and frigates. It is recognizable by the latticework support holding all 3 antennas away from the structure of the ship; in FRAM destroyers SLA-12 is the antenna set on the after deckhouse.

The trainable AS-1751 carries 3 radomes on top, and a fourth horn below, separated by a mid-section pedestal. The upper set consists of a conical ECM receiver with skewed DF horns on either side; the lower radome covers the transmitting horn. Each set weighs 193 lb. Power rating is 25 kW peak, 1 kW average. The ECM horns may be either wide (low gain) or narrow (high gain) with, respectively, 17-deg and 8-deg beams.

Of the 2 AS-1750 antennas, the lower is used to transmit and the upper to receive. Each consists of a microwave horn covered by a radome, and each covers 180 deg in azimuth. Power rating is 25 kW peak, 1000 W average. The trainable AS-1751 consists of 2 trainable antennas. The upper consists of a conical receiving horn flanked by skewed direction-finding horns. The lower antenna is a transmitting horn. The transmitter may use either a narrow high-gain (8-deg beam) or a wide low-gain (17-deg beam) horn antenna.

◆ SLA-15

Analogous to SLA-12, SLA-15 has a different frequency range. SLA-15 is used as part of ULQ-6. SLA-15 consists of a trainable AS-2431 antenna flanked above and below by 2 AS-2430 fixed auxiliary antennas; 1 unit is mounted on each side of a ship. As in SLA-12, 1 fixed antenna is a receiver, the other a transmitter. Beam size is 17×155 deg.

The trainable AS-2431 is recognizable by its set of 3 horns, in radomes on a common base, above a fourth horn. All 4 train together, as a unit. Of the 3 upper horns, the outer ones are DF horns and the middle one is the ECM receiver; the lower horn is the ECM transmitter. The ECM horns may be either wide (18-deg) or narrow (9-deg) beam types. Peak power is 25 kW in both subunits.

SLA-18 is a supplemental antenna system consisting of 2 AS-2430s, but without the rotatable element of SLA-15.

◆ SLQ-17

Hughes's jammer/deception system for carriers replaces the earlier ULQ-6. SLQ-17 is automated, tracking threats and providing a combat system with identification information. Originally unreliable, SLQ-17 was unpopular. However, in 1985 Hughes claimed that the system had been cured, that its MTBF had improved from 20–30 hr to 250 hr (availability increased from 25 to 97%). Nevertheless, to increase standardization, SLQ-17 is being replaced by SLQ-32(V)3.

Like other jammers, SLQ-17 incorporates a receiver matched to its transmitter. Unlike its predecessors, SLQ-17 uses electronically steered reception and jamming beams and, thus, can scan very rapidly. However, because it lacks a multiple-receiver lens (like that of SLQ-32), it has only a single beam in each frequency range or for each set of transmitters.

The roll-stabilized aluminum box contains paired antennas, to cover its frequency ranges. The outward-facing side carries a pair of flared horns at its top and another at its bottom, 1 pair (representing 2 frequency ranges) presumably for reception and the other for transmission. Between the 2 is a pair of semicircular slotted waveguides (of 2 sizes) called parabolic toruses, each enclosed in a semicircular reflector. Each port in the waveguide is used to generate a different beam. As a transmitter or receiver is switched from port to port, the beam, in effect, sweeps across a broad angle, up to 180 deg. The more numerous the switches, the finer the beam. A Hughes drawing suggests that the big horns scan mechanically, albeit over a limited angle. Unlike the semicircular antennas, the horns are duplicated top and bottom on the beam face of the SLQ-17 box, a practice that suggests that 1 set transmits while the other receives.

SLQ-17 on board a carrier. (Hughes)

Each of the 2 angled faces of the radome carries a pair of semicircular slotted waveguides (1 atop the other) at its top and a pair of horns at its bottom. Presumably, each of the broadside semicircular antennas covers 180 deg; each of the antennas in the angled faces covers 90. Since beam shapes match, either set could receive for the other; if the broadside antennas receive, then the antennas in the angled sides could be used to transmit,

(Below) The *Enterprise* shows an SLQ-17 antenna outboard of her angled deck, on a trellis mast, February 1986. (Hughes)

and the system could jam 2 targets on each side at the same time. If that is correct, then the 2 pairs of horns on the broadside are both jammers (again, to deal with 2 targets at once, which was presumably the specification for the system), and the single pair of horns in each angled face is a receiver/tracker.

The entire assembly is 68 (high) $\times$ 71 $\frac{3}{4}$ $\times$ 50 in and weighs 1200 lb (for each side).

Carriers are equipped with SLQ-17A(V)2. The associated computer is UYK-20. The first production contract was let early in 1978, with options for 2 or 3 more. The first was installed on board the *Enterprise*. The fourth was delivered early in 1983; 8 had been delivered by late 1985. The FY80 program included funds for integration with NTDS. An upgrade program began in 1985. SLQ-17A(V)2 installations: FY80, CVN 65 and CV 66; FY82, CVN 70; FY83, CV 64; FY84, CV 41, 43, 63; FY85, CV 62, CVN 71; FY86, CVN 72, 73. As of FY87, unit cost was about \$2.8 million, compared to an estimated \$7.2 million for SLQ-32(V)4, its replacement.

SLQ-51, a projected advanced version of SLQ-17, was canceled in favor of further SLQ-32 development.

SLQ-29 is a combined WLR-8/SLQ-17 package installed on board 20 U.S. warships about 1976.

◆ SLQ-32/Sidekick

SLQ-32, manufactured by Raytheon, is the current standard U.S. Navy ECM system. It was the successful competitor in the Design-to-Price EW System (DPEWS), beating the Hughes SLQ-31 (which in turn became the basis for the current Taiwanese navy ECM system). The DPEWS RFP was issued in October 1973, and Phase I contracts for studies were let in January 1973. Phase II (hardware) contracts followed that October. A total of 6 design studies narrowed down to SLQ-31 and -32, which were evaluated in 1975-77. SLQ-32 was operationally evaluated February-September 1976, and its selection was announced in February 1977. As of March 1989, 360 SLQ-32s had been bought.

This system uses an internal library to automatically detect and categorize threats. The (V)3 version can also jam. Other versions are used to trigger such defensive reactions as chaff and weapons firing. Reportedly SLQ-32 does not automatically steer a ship away from its own chaff cloud, as some foreign systems

SLQ-32(V)2, USS *William S. Sims*, 1986. The upper antennas cover Band 3, the lower (larger) ones Band 2. The flat plates cover the DF lenses; the semicircular radomes cover semi-omni antennas. The system also includes Band 1 quadrant antennas at the yardarms. The simpler (V)1 version is limited to the Band 3 antennas but uses the same box as (V)2. (L. van Ginderen)

SLQ-32(V)3 on board the replenishment ship *Kalamazoo*, 1988. The lowest set of plates cover Band 3 transmitter antennas (for jamming). In contrast to the (V)1 and (V)2 versions, the box is roll-stabilized. (W. Donko)

SLQ-32(V)3 on board the battleship *Wisconsin*, 1988. The small box under the main SLQ-32 box carries Band 1 antennas; it is usually mounted at the end of the yardarm, but this ship has no suitable location other than that at the head of the fire-control tower. (S. Terzibaschitsch)

SLQ-32(V)3 on board the missile destroyer *Dahlgren*, 1986. The 2 flanking radomes contain lens antennas that improve Band 1 DF accuracy, for antiship missile targeting. (Author)

may. Versions are: (V)1, radar warning on H- through J-bands, for auxiliaries and amphibious ships (most will be upgraded to (V)2); (V)2, radar warning on B-J-bands, for newer destroyers and frigates (replaces WLR-1 where fitted); (V)3, radar warning on B-J-bands and jamming/deception on H-J-bands, for battleships, cruisers, DDG 37 class, and major amphibious ships; and (V)4, for carriers (to replace SLQ-17). Modular design allows for upgrading from one variant to the next.

The system is designed to handle 3 frequency bands: (V)1 is limited to band 3 (missile seekers), and (V)2 and (V)3 are extended to bands 1 and 2. The band 3 receiver is wide-open in direction and in frequency, using 2 stabilized-lens direction-finders (each covering 90 deg) and a semi-omnidirectional antenna that senses the dominant pulse in the incoming energy for instantaneous frequency analysis. For band 2, (V)2 adds 2 more lens arrays and another semi-omnidirectional receiver. For band 1, (V)2 uses 4 masthead spiral antennas, typically 2 each port and starboard. The (V)3 transmitters are located in the bottom of each box. The band 1 antenna is AS-3316, and is unique to the SLQ-32.

The (V)1 antenna assembly weighs 1560 lb, (V)2 2400 lb, and (V)3 5000 lb. Band 1's lens antennas are $25 \times 13 \times 18$ in (30 lb).

The key to SLQ-32 performance is the use of an internal beam-forming lens. Each position on the inboard side of the lens corresponds to a beam direction, as represented by signals on the outboard side of the lens. Thus a signal fed into the appropriate position on the inboard side produces signals all along the outboard side, with appropriate phase differences, which can be transmitted by a series of wide-angle antennas. The phases applied to these antennas produce a net beam in the appropriate direction. Because the system is linear, the same lens can serve a series of inboard elements, each representing a different beam

SLQ-32 integrated polar display, showing own-ship and friendly emitters in the center circle, hostile missiles in the broad middle ring, and hostile nonmissiles (such as ships) in the outer ring. That arrangement corresponds roughly to frequency, since missiles (with the smallest available space for antennas) generally operate at the highest frequencies, and the least urgent threats, ships, operate at the lowest. Engagement data and further emitter data for analysis and identification are displayed around the edges of the 8 × 10-in CRT. (Raytheon)

direction, simultaneously. Similarly, the lens converts an incoming beam in a particular direction into an output, inboard, at the element representing the appropriate direction. Each element enjoys the same gain, given by the total aperture.

This is very different from a nonlens system like the Hughes SLQ-17 or SLQ-31, in which a series of phase shifters generate a single beam. The single beam can scan rapidly, but it cannot be everywhere at once.

Each band covers more than an octave in frequency. The scheme of installation suggests that band 3 covers missile seekers (J-band), band 2 covers aircraft radars (E-I-bands), and band 1 is lower frequencies, probably C/D-bands.

Band 1, the lowest frequency range, uses planar-spiral antennas similar in concept to those in aircraft RWRs, which have relatively little resolution. This frequency range probably includes such major Soviet air-search radars as Top Sail and Sky Watch and so can be useful for antiship-missile targeting. There is a current effort to improve DF accuracy by changing to a different antenna in this band. Presumably, the original SLQ-32 used a very simple band 1 antenna because it was intended primarily as warning that a major Soviet unit, which might be able to fire missiles, was present. ARGOSystems began producing band 1 improvement kits under a January 1985 contract. Operational test and evaluation of the SLQ-32 improvements for OTH Detection (OTH-D low-band improvement) was completed during FY88.

The band 2 DF antenna uses a linear array of 38 vertical horns to cover 90 deg. The horns feed 9 receivers through a microwave lens. Effective beamwidth is therefore 10 deg. The lenses are built up of parallel plates built in stripline form using printed circuits.

The band 3 DF antenna uses a linear array of 66 horns to cover 90 deg, feeding 17 receivers through a microwave lens; each beam is therefore 5.3 deg wide.

The band 2 and 3 antennas are mounted in a stabilized box, with the flat lens-fed arrays radiating at 45 deg to the centerline of the ship, and a stack of semi-omnidirectional antennas (with semicircular radomes) directed out on each beam. These latter antennas are used to pick up the dominant pulse in each train, for IFM.

Raytheon backs the array of receivers with a series of crystal video receivers plus an IFM. The alternative Hughes proposal, for SLQ-31, was a scanning superheterodyne. Coarse frequency data (from the IFM) and amplitude data (from the DF array) are combined in a direction/frequency correlator; time-of-arrival data are added to form a pulse word, stored by frequency and angle in an emitter-file memory. If 3 or more identical pulses are received within a programmable interval (up to 32 msec), the digital tracker decides that a new emitter is present, and additional data are collected for analysis. PRF, scan type, scan period, and frequency are all extracted.

The corresponding jammer also uses a lens, interposing a TWT between each point on the lens and the corresponding horn radiator, for a total of 140 moderate-power TWTs. They amplify the jamming signals generated on the other side of the lens, with appropriate phases imposed by the lens. There is no beam-switcher passing high microwave power, and total jamming power is the sum of the power of the TWTs. The jammer is fed by a 35-element linear horn array, and it forms 64 beams on either side of a ship. Total radiated power is reportedly 1 MW. Jamming modes include RGPO and AGPO, the latter jamming CW missile-guidance radars. It is claimed that the system can jam 75 hostile threats simultaneously, each with a separately tailored countermeasure.

Current SLQ-32 and other U.S. ECM improvement programs include SADI/DDI (shipboard automatic decoy integration/DECM decoy integration), a tactical emitter feature (TEFE) for SLQ-32, improved antiship-missile/deception ECM (ASM/DECM), countertargeting countermeasures, and the EW Control System (EWCS)/Rapid ASMD Integrated Defense System (RAIDS). The FY90 program includes exploratory work on a new real-time adaptive monopulse countermeasure, which is to be tested at sea in FY91, and to begin formal development in FY92.

The initial SLQ-32 development contract was awarded in May 1977, with first production deliveries in June 1978 (final sea trials were on board the cruiser *Leahy*). It covered the first 3 versions.

(V)1, (V)2, and (V)3 all use UYK-19 computers. Originally, all had 64-kword memories. There have been 3 upgrades. First the (V)3 version was increased to 96 kwords. Then all versions were increased to 128 kwords, primarily to accommodate CDS integration (although this was not done in all ships, the new configuration was made standard). The latest digital processing unit (DPU) upgrade is to 512 kwords, and in the (V)4 version there is an adjunct processor (256 kwords) as well as the main unit. The 512-kword version includes an embedded 20-Mbyte hard disk. The display console memory has been upgraded as well, from 4 kwords (16-bit words) to 16 kwords. The 512-kword upgrade is part of a larger Phase B upgrade that increases band 3 sensitivity and suppresses interference. Other major improvements under the FY85-88 programs were higher-angle coverage (HAT) for band 3 and the much increased DF accuracy (by about an order of magnitude) for band 1.

The new (V)4 version, for carriers, employs fiber optics. The first was on board the *Saratoga*. It is also to be installed on board the *Kitty Hawk*, *Enterprise*, and *Forrestal*. The major improvements are a digital memory for faster threat evaluation and improved interference suppression (presumably between the jamming and sensing elements). Some components are as much as 300 ft apart. The system uses 2 computers, each near 1 set of transmitter/receivers, which are connected by fiber-optic cables for fast data exchange. The wide separation between components results entirely from the broad beam of the carrier, which complicates coordination between elements of the system.

The V(5) designation (possibly unofficial) is for V(2) plus Sidekick. Current plans call for *Spruance*-class destroyers to be upgraded from (V)2 to (V)3. There has been some question as to whether the *Arleigh Burke*-class can be upgraded similarly. *Knox*-class frigates are being upgraded from (V)1 to (V)2. Other frigates and coast guard cutters have the (V)2 version. (V)3 is installed on board (or planned for) the fast combat support ships (AOE and AOR), the battleships, the cruisers, the *Kidd*-class

destroyers, the *Mahan*-class destroyers (the *Adams* class have the (V)2 version), the amphibious flagships (LCC), and the amphibious carriers (LHA, LHD, and LPH). *Perry*-class frigates have the (V)2 version but are scheduled for installation of the Sidekick independent jammer. Sidekick is similar in concept to (V)3, but with lower radiated power.

Unit prices, as of early 1989, were \$335,000 for (V)1; \$600,000 for (V)2; about \$5.4 million for (V)3; and about \$7.2 million for (V)4.

As a result of the attack on the frigate *Stark*, existing SLQ-32(V)2s on board selected *Perry*-class frigates are being modified with a separate jammer, designated Sidekick. Raytheon had already developed such a system for the Taiwanese navy some years ago; the company took about 3 months from initial request (7 weeks from contract award) to first installation. The U.S. Navy bought 13 Sidekick sets through late September 1990, and on 29 September ordered 8 more. The original orders were prompted by Persian Gulf operations during the Iran-Iraq War.

◆ SLQ-33

See the ASW section.

◆ SLQ-34

This new-generation (1986) cover and deception system uses 2 small antennas, 1 for reception and 1 for transmission (about 30 lb each, approximately 20 × 15 × 15 in). They will probably be masthead-mounted.

◆ SLQ-35

See the Mine Warfare section (countermeasures).

◆ SLQ-36

See the ASW section (torpedo countermeasures).

◆ SLQ-37

See the Mine Warfare section (countermeasures).

◆ SLQ-39

Chaff buoy.

◆ SLQ-41 through -47

Active expendable EW buoys.

◆ SLQ-48

See the Mine Warfare section (countermeasures).

◆ SLQ-49

SLQ-49 is an inflatable decoy or "Rubber Duck"; it is the U.S. version of the British DLF. See above for details.

◆ SLQ-50

SLQ-50 is E-Systems's surface-ship terminal for the Battle-Group Passive Horizon-Extension System (BGPHEs), the airborne passive electronic-intelligence collector. The original contract was awarded in 1984, and the first SLQ-50 was shipped for installation in 1987. SLQ-50 consists of 4 UYK-44 computers and 3 UYQ-23 terminals connected by a Militarized LAN (MLAN).

Plans for the shipboard BGPHEs terminal were revised about 1989, the UYK-44 computers being replaced by DTC IIs. The change was expected to reduce cost and risk, and also to help bring BGPHEs into a new common architecture using standard computers and LANs. It then becomes much simpler to connect BGPHEs to systems such as JOTS, and the intelligence personnel handling and maintaining the major systems need become familiar with only 1 set of terminals (although the different systems do remain distinct).

◆ SLR-12A

This wide-band shipboard EW direction-finder uses a rotating directional microwave antenna in a radome. The antenna itself (AS-2209, formerly AS-1789) is a small paraboloid feeding a horn in the upper part of the radome. The antenna is mast-mounted.

◆ SLR-16

This HF SIGINT receiver uses SRD-19 arrays. SLR-16 automatically seeks and acquires signals, then selects those of interest for further analysis while avoiding set frequencies of no interest, e.g., those used for friendly communications. SLR-16 and SRD-19 are used together in the Classic Outboard (SSQ-72) system.

◆ SLR-21

This ESM system for small ships, made by EM Systems, was announced in 1978. The broad-band DF antenna consists of 4 cavity-backed spiral antennas, with 4 crystal video receivers, apparently with associated IFMs. Frequency range is 2–18 GHz, and the claimed direction-finding accuracy is better than 10 deg. SLR-21 is an automatic table look-up system, and in 1978 the manufacturer claimed that SLR-21 could cope with up to 200,000 pps. The display is a table of parameters of the detected emitters.

SLR-21 was developed specifically for the *Pegasus* class, with a projected unit cost of \$30,000.

SLR-21 was chosen in favor of an alternative Amecon SLR-20, a fully automatic system developed from the ALR-59 used on board the E-2C.

◆ SLR-22

A cover and deception device for carriers, SLR-22 was developed about 1985.

◆ SLR-23

An intercept direction-finder in the J-band, SLR-23 works with WLR-1 and SLQ-32.

◆ SRD-19

AS-3112/SRD-19 antennas, part of the Classic Outboard suite, are shown at the masthead of a British Type 22 frigate: the DF array covers the VHF range in 3 bands. The upper 2 are covered by Adcock arrays, the lower by closed loops. The entire array is 85 in high. The 2 cylindrical objects below the array are UHF receive and transmit antennas. (A. Raven)

SRD-17 (AS-3202) deck-edge antenna, USS *Mississippi*, June 1988. (Stefan Terzibaschitsch)

SRD-19 is a system for exploiting SIGINT (LF/MF/VHF) and is part of the shipboard Classic Outboard (SSQ-72) system. SRD-19 uses 24 small deck-edge antennas in 3 groups of 8 (LF/MF-HF). These antennas include standard communications antennas (for target acquisition and reference: 1 combination would be a 10–30 MHz inverted cone, a 35-ft 2–35-MHz whip, and 2 broad-band discages), and an Adcock-type VHF D/F array (dipoles and crossed loops) mounted in 3 tiers on the masthead. SRD-19 is often used with SLR-16. In that application SLR-16 has priority over the DF functions.

The deck-edge antennas are electronically switched in sequence to form receiving beams. The masthead array (AS-3112/SRD-19) includes both a wide-open directional system and a wide-band target-acquisition/reference system.

◆ SRS-1 (Combat DF)

Combat DF is a less elaborate (own-ship) version of Outboard (SSQ-72/108) for missile targeting. Compared to Outboard, Combat DF lacks any intelligence function; Outboard is more an intelligence than a targeting system. It is concerned mainly with HF communications signals and can exploit their internal details to at least some degree. Combat DF operates over a broader band and was conceived primarily to support the Tomahawk antiship missile. Block 0 is basic step-search signal acquisition and DF against communications signals. Block 1 adds a modular subsystem, the foundation for future automated signal acquisition. The first 8 Block 0 systems are in production; delivery was to be completed in the 1st quarter of FY91 (October–December 1990). More may be ordered under the FY91 program. Plans originally called for SRS-1s on board the battle-ships, the *Wasp*-class amphibious carriers, and 14 *Spruance*-class destroyers. It is currently planned for selected destroyers and missile destroyers, as well as selected amphibious ships. To at least some extent SRS-1 superseded SSQ-72. SRS-1 in turn has largely been superseded by SSQ-108, more of which were bought than SSQ-72 and SRS-1 combined. Presumably, that development reflects the greater interest in connectivity (as symbolized by the emergence of JOTS) and the growing importance of OTH data not only for targeting but also for other operations.

Combat DF encountered severe cost, scheduling, and technical problems, and for a time was close to cancellation. About 1988 it was very nearly combined with BGPHEs to save it.

Sanders is the major contractor.

◆ SSQ-70

SSQ-70 is a system for collecting operational intelligence.

◆ SSQ-72

See SRD-19 and SLR-16 above. SSQ-72 consists of SLR-16, SRD-19, and a local monitoring station; a phase 2 program added SLR-23 and SYQ-8 for target identification. It was conceived in the late 1970s, as part of the same OTH-T program that gave rise to Outlaw Hawk and then to TFCC. Plans originally called for 2 Outboards per carrier battle group; 24 were ordered for missile cruisers and destroyers (to match 12 deployable carriers), plus 6 more to make up for ships that might be unavailable. Ships carrying SSQ-72 are intended to provide data for their entire battle groups and are linked with each other and with shore stations by satellite. See also Combat DF (SRS-1) and the various OTH systems described in the Surveillance and Control section.

◆ SSQ-74

A van-mounted radar and communications simulator, SSQ-74 is called ICADS (Integrated Cover and Deception System). SSQ-74 may be temporarily installed on a destroyer's weather decks; ICADS has a gross weight of 18,000 lb (1974). This system is now being modernized. The current prototype is on board the *Comte de Grasse*.

◆ SSQ-80A(V)

SSQ-80A is a portable (carry-on) 2-operator, 3-rack, automated communications-signals collection, analysis, and exploitation unit, for signals between lower MF/HF and V/UHF. An automated radio-frequency management system (RFMS) distributes collected signals, protecting the system from local interference and also conditioning the received signals for analysis. Audio distribution, recording, and storage are also automated, and the system incorporates a computer data base (e.g., of technical data references, threat profiles, and activity summaries). Output may be by printer, paper tape punch, or cryptographic device. Major contractors include Engineering Research Associates (ERA), Electronic Support Systems Inc. (ESSI), and Cubic Communications.

◆ SSQ-82

SSQ-82 controls a ship's electronic emissions (MUTE: Multiple Unit for Transmission Elimination). By centralizing control of all electronic emissions on board a ship, MUTE makes full electronic silence possible.

◆ SSQ-91

SSQ-91 is the communications simulator in the *Kidd* class.

◆ SSQ-108

Outboard, superseding SSQ-72 and parallel to SRS-1, is for real-time OTH passive detection, localization, and targeting of hostile emitters. There are 2 phases:

Outboard I (SSQ-108(V)1) consists of SRD-19A, the SLR-16A countermeasures receiver, the OK-324/SYQ system-supervisor station (SSS), the local monitoring station (LMS), and tactical intelligence (TACINTEL) communications.

For Outboard II (SSQ-108(V)2), the SLR-23 automated narrow-band acquisition system and an OK-324/SYQ modification kit have been added.

SLR-16A, SLR-23, and LMS detect and recognize signals; SRD-19A provides sufficiently accurate DF for targeting. The SSS provides the interface to the ship's CIC and to off-board systems (other Outboards, the shore HF/DF Bullseye net, and the future Combat DF system). Outboard has been installed on board 36 selected DDs, CGs, and CGNs. The major contractors are UNISYS, Sanders (which is responsible for the DF portion of the system), and Southwest Research Institute.

◆ URD-9

URD-9 is a radar D/F (225–400 MHz).

URD-27

URD-27 is a broadcast-frequency D/F for SIGINT (250 MHz–8 GHz).

ULQ-6 and SLQ-22/23/24/30

ULQ-6 is a deception repeater/jammer for cruisers and destroyers, often found on board ships transferred abroad. ULQ-6 has been almost completely superseded in U.S. service by SLQ-32. For details of the antenna system, see SLA-12 and SLA-15 above.

ULQ-6 is a deceptive repeater, conceived primarily to defeat the conical-scan seekers of early Soviet antiship missiles such as AS-1 and then SS-N-2. It produced a false target and, thus, could function as a track-breaker. Later, in the late 1960s, ULQ-6 was improved by the addition of an RGPO capability (swept audio). The original amplifier (1 kW) was replaced by a higher-powered unit (20–25 kW). About 1968 many ships were fitted to react automatically to the 3 main threats either present or expected in Vietnam, Styx, SS-C-1, and SS-C-2.

ULQ-6 was developed alongside the ULQ-5 S-band blip-enhancer. In theory, the effect of ULQ-5 was to prevent a Soviet bomber from deciding which in a formation of ships was the carrier. If it failed, ULQ-6 provided self-defense. In practice, ULQ-5 was unpopular since each ship carrying it was a likely target, and it never appeared in any numbers. ULQ-6 became the standard U.S. deception jammer, 2 (port and starboard) being placed aboard each ship from destroyers up. The original ULQ-6 concentrated on I-band, but ultimately the system covered the range G-I.

ULQ-6 was derived from the ALQ-32 airborne deception repeater, and it was first tested in 1959. At that time the AS-1 threat was quite urgent, and initial installations (1959) were of ALQ-32s in huts, which could be placed aboard selected carriers by helicopters. Initial tests of ULQ-6 showed that it could handle up to 3 pulse chains simultaneously, but against more it tended to provide the same signal to all incoming pulses.

The original ULQ-6A was the 1-kW anti-conical scanning device for destroyers. The operator slewed the horn antenna

ECM arrays associated with ULQ-6B, on board the destroyer *Hamner*, 1965: [32] AS-1750/SLA-12; [34] AS-1341/ULQ-5AX (receiving); [36] AS-1751/SLA-12; [38] AS-1750/SLA-12 (transmitter). The big radomes are direction-finders containing spinning antennas: [29] AS-570/SLR; [30] AS-571A/SLR; [31] AS-616A/SLR. Number 25 is a "sword" [66132], and number 28 is a "derby" [66131]. Antenna 42, on the foremast, is AS-1789/SLR-12. (U.S. Navy)

ULQ-6 on board the carrier *Coral Sea* at Norfolk, 1986, with the array trained. The middle portion of the antenna is SLA-12 or -15. (S. Terzi-baschitsch)

toward the threat, which was generally indicated by separate ESM equipment. ULQ-6B added the RGPO mode. Carriers had a similar system, probably ULQ-6C, with a narrower beam.

At least from 1968 on, all versions have employed a pair of fixed radomes with a trainable array between them; surviving examples have AS-1750/1751 and AS-2430/2431 antennas. The fixed antennas provide unfocused countermeasures against other targets. The modern trainable antennas, but not the earlier ones, include DF antennas. These probably feed an automatic target tracker. In the original system, the operator probably used a single ECM receiver antenna, colocated with the transmitting horn, both as a receiver of target pulses and as an indicator that the transmitter was pointed appropriately.

ULQ-6 on board the Canadian Tribal-class frigate *Iroquois*, 1986. The arrays differ from those in U.S. ships, but the system is the same. The arrays are visible along the barquette under the Signaal "egg" on the near side of the ship. (Author)

ULQ-6 was used in combination with chaff launchers: the jammer would break a missile's track, which would then transfer to the chaff cloud (see the account of U.S. chaff rounds below). ULQ-6 was the basis of the ECM/chaff systems added to U.S. warships on an emergency basis during the Vietnam War, both in the Western Pacific and in the Mediterranean.

This system currently equips Canadian frigates. In 1987 an additional coherent countermeasures processor (CCP), to be added to ULQ-6 on board all 17 Canadian frigates, was announced. CCP contains its own 500-radar threat library and can deal with such ECCM techniques as pulse coding and pulse compression. Instantaneous bandwidth is up to 550 MHz. CCP is manufactured by Telemus Electronic Systems.

SLQ-22/23/24 are high gain versions of ULQ-6, using the same SLA-12 or -15 antennas. SLQ-30 is an updated ULQ-6 by Kuras-Alterman (TRUMP, or Threat-Reactive Update and Modernization Program).

During the mid-1970s the U.S. Navy encouraged buyers of former U.S. destroyers (which were equipped with ULQ-6) to adopt the SLQ-30 upgrade. SLQ-30 added a channelized receiver to ULQ-6B and -6C, at a cost (in 1975) of \$250,000. It used the SLR-12 receiver, the spinning DF antenna of which was carried in a small separate radome (19 in in diameter, 31.9 in high). Presumably, the extra antenna was needed to extend system coverage to higher frequencies.

◆ WLQ-4

The *Sturgeon*-class submarines' ESM system (Sea Nymph) was developed by GTE-Sylvania. WLQ-4 searches automatically for unknown signals. Presumably, it was developed for electronic reconnaissance: in 1975 it was revealed that for some time *Sturgeon*-class submarines had been employed in that role. The U.S. FY84 budget included upgrades of existing systems to WLQ-4E configuration. The FY85/86 budget included concept definition of a next-generation version, WLQ-4(), looking toward a competition for full-scale engineering development to begin in FY87, to meet new operational requirements. However, it ap-

pears that instead a repackaged version, WLQ-4(V)1, will be installed on board new *Sea Wolf*-class submarines.

◆ WLR-1/WLR-11

WLR-1 was the standard U.S. radar-warning system of the 1960s, for both surface ships and submarines. As such it has been transferred to many friendly navies, and it continues in U.S. service. WLR-1's chief disadvantage was that the operator had to search manually through the frequency range(s) and so could easily miss transient signals. That limitation was acceptable for electronic intelligence gathering but not for quick reaction to an incoming missile. On the other hand, WLR-1 was liked for its resolution and for its very wide bandwidth covering VHF through SHF (50 MHz–10.75 GHz). WLR-1 simultaneously finds the direction of a selected signal and displays information.

WLR-1 uses a combination of wide-open fixed antennas (NT-66131 for UHF [300–3000 MHz] and NT-66132 for VHF [40–300 MHz], the "derby" and "sword," respectively; and the AS-1174 [or AS-3200] for UHF/SHF, a tape-wound cone) and rotating DF antennas in radomes (AS-571, AS-616, and AS-899; in some cases the roles of AS-571 and -616 are combined in a single AS-1023 antenna). In FRAM destroyers the radomes are typically located atop the after deckhouse, near the ULQ-6 arrays. The sword/derby combination has been in service since World War II and is used in the Royal Navy as well. Scan rates for AS-571 and -616 are 0–250 rpm; for AS-899, 300 rpm maximum. Beamwidths: AS-571 (300–600 MHz), 50 × 90 deg at lowest frequency to 30 × 70 deg at highest, combining vertical and horizontal dipoles; AS-616 (550–2600 MHz), 35 × 85 deg to 20 × 70 deg on low band and 35 × 70 deg to 20 × 50 deg on high band (vertical horns 20 × 95 deg to 10 × 65 deg on high band); AS-899F (1 GHz–20 GHz, i.e., bands 6 through 10), 40 deg in horizontal width at lowest frequency, 4 deg at highest.

AS-571 uses a double-sided high-gain dipole array, 1 side of the array acting as a reflector and the other as a planar surface. Three dipoles are mounted vertically on the planar surface, and 2 are mounted horizontally on the corner reflector, so that the antenna can receive both vertically and horizontally polarized signals, although only 1 polarization is selected at any 1 time. AS-616 uses similar dipoles, 6 arranged horizontally on 1 side and 3, vertically, on the other, to intercept signals in the lower UHF band. Below the dipoles it carries waveguide horns, 4 mounted vertically on 1 side and 4 horizontally on the other, to receive signals from the higher UHF band. The radome is identical to that of AS-571 (diameter 45¹¹/₃₂ in, height 62 in), but the antenna inside is much heavier (total weights are 250 lb for AS-571 and 425 lb for AS-616).

A "sword" antenna typical of those feeding the WLR-1 pulse analyzer. This is on board a British ship, but U.S. "swords" (i.e., monopoles emerging from ground planes consisting of a few wires) are identical. WLR-1 also employs higher-frequency "derby" antennas, which are analogous in design. (A. Raven)

The current AS-899F is a more complex antenna, consisting of a stationary spiral feed, a multiplexer, and a reflector tilted at about 45 deg so that it always focuses signals on the stationary feed. This type of construction is quite common in the spinning ESM antennas developed during the 1950s and 1960s. Earlier versions were more complex, with 4 feed horns, 2 at the top and 2 at the bottom of the antenna, and a spinning reflector, angled at 45 deg. These antennas were more limited in frequency response (to bands 7, 8, and 9, because the horns were not broad-band antennas). AS-899F is 34 in in diameter and 82 in tall and weighs 268 lb. AS-1174 is an omnidirectional broad-band antenna, for UHF through low SHF in 3 bands (designated 7, 8, and 9: 300–2450 MHz, 2450–4375 MHz, and 4375–7350 MHz). It employs 2 strips of aluminum tape spiraling up a fiberglass cone; a triplexing filter separates signals from the 3 bands. The basic frequency of the antenna is determined by its apex angle; bandwidth is determined by the tightness of the spiral. The antenna itself is 16.5 in in diameter and 41.5 in high (weight 11.25 lb). Existing AS-1174s are being replaced by AS-3200s, which are very similar in shape but are larger, with 4 spiral copper bands (diameter 30.3 in, height 45 in, total weight 45 lb.)

WLR-11 is an IFM system. It also adds capacity through J-band to the basic WLR-1 system. WLR-11 uses the same antennas, for the 7–18-GHz frequency range. WLR-11 is being added to existing WLR-1 systems, the designation of the new configuration being WLR-1G. It incorporates an automatic look-up feature. For its IFM function, WLR-11 adds a further omnidirectional antenna, AS-2918/S, a fiberglass cylinder housing a biconical horn, a polarizer, and a diplexer. The horn consists of 2 cones, apex to apex, with a small gap between, this region forming the antenna aperture. The pattern is omnidirectional and is at least 25 deg wide in elevation. The diplexer breaks received signals into 2 bands: 7–11 GHz (low pass) and 11–18 GHz (high pass). The entire antenna is only 6.3 in in diameter and 24 in high (the attached preamplifier is considerably larger than the antenna proper), and it is typically mounted on a yard-arm or other high horizontal position. The manufacturer is ARGOSystems.

The current version is WLR-1H, which scans automatically and covers a wider bandwidth (0.55–20 GHz). It was adopted instead of the more expensive WLR-8(V)4, the latter being canceled in September 1983. This was partly a demonstration of the effect of the procurement process. Since -1H was, in theory, no more than a minor improvement over earlier versions of the same device, it could be developed very quickly and at relatively low cost. It was, therefore, actually a generation or more *ahead* of WLR-8(V), which had been developed from the beginning as a new system. The most important new feature of -1H is fast electronic scanning of its frequency bands, for much greater probability of intercepting short signals. Each tuner is micro-processor-controlled, and a central processor manages the system as a whole. WLR-1H retains the individual-signal manual-analysis capability (for which WLR-1 was valued) and adds a threat library and an automatic search-and-signal-identification mode. The kit that upgrades a WLR-1 to -1H standard costs about \$900,000, and the system is used by the Australian and German navies as well as by the U.S. Navy. Low cost (compared to the alternative WLR-8 system) reflects the rapid fall in electronics prices. In addition, a WLR-1 could be upgraded relatively easily, whereas WLR-8(V)4 installation required a shipyard availability.

In 1983 it was reported that a WLR-1H cost less than half as much as the WLR-8(V)4 it was replacing.

Work on WLR-1H can be traced back to 1979 contracts let to ST and to ARGOSystems for upgrades including improved signal-processing equipment. In 1981 ST began work on upgrading the WLR-1G signal-acquisition interface, and ARGOSystems began work on improvements to -1G signal-processing units. Improvements in -1H are officially listed as a new Signal-Acquisition System (SAS) and/or Upgraded SAS (depending on which model of WLR-1 is replaced), a Signal-Processing Unit

(SPU), an Emitter-Classification Unit (ECU), BITE, and Enhancement Modules (DFEMs).

Existing WLR-1, -1B, -1D, -1F, and -1G are being replaced by -1H. Existing WLR-1C are being upgraded to -1H standard. The first 10 *Spruances* were fitted with -1G as an interim measure.

◆ WLR-3

WLR-3 is a radar-warning and signal collection system for surface ships and some submarines.

◆ WLR-4

WLR-4 is an ESM receiver, part of Shortstop.

◆ WLR-5

WLR-5 is an acoustic intercept receiver.

◆ WLR-6

WLR-6 is a reconnaissance signal-collection system. In submarines, this device is called Waterboy.

◆ WLR-8

WLR-8 is a radar-warning system for sequential or simultaneous scan over the 50 MHz–18 GHz spectrum. Signals are automatically classified and recognized on the basis of PRF, frequency, modulation, pulse width, amplitude, and scan rate. The system can trigger threat warnings for particular signals. It can also be directed to search particular frequency segments on a priority basis. This is currently more a signals-intelligence than a tactical system although it is compatible with NTDS; it is not used for automatic direction of jammers or weapons.

WLR-8 employs 7 electronically swept, octave-band, super-heterodyne receivers, to achieve high sensitivity and accuracy. All but the lowest-frequency band (which is varactor-tuned) are YiG-tuned. Three more tuners are available as reserves or for expanded frequency coverage. The system can operate with any of the U.S. Navy's standard rotating DF antennas, either manually or by computer control. The display is a 5-trace CRT; the upper 2 traces, which can be switched to any tuner, show amplitude vs. frequency. The next 2 are A-scans for manual PRF (actually PRI) measurement. The last is used for signal analysis. A PS-300 computer is used for system control, signal acquisition/analysis, and file processing.

WLR-8 was originally to have been purchased for both submarines and surface ships, but after protracted development the surface-ship version was canceled in September 1983 in favor of WLR-1H.

WLR-8 was conceived in 1968, and in 1971 GTE-Sylvania won a design competition, beating Watkins-Johnson, ITT, and Loral. The requirement was urgent because the Shortstop antimissile ECM program had just been canceled because of its high cost. Ironically, the surface-ship version of WLR-8 later died for the same reason.

Originally, 3 versions were planned: WLR-8(V)1, which was not built, was the basic computer-aided surveillance system. (V)2 added automatic signal acquisition, parameter measurement, and a threat-alarm function (Scan Lock). It was intended primarily for submarines. (V)3, for destroyers and larger surface ships, was (V)1 plus an interface to NTDS. (V)3 in turn was superseded before production by (V)4 Mod 1, which benefited from submariners' experience. Improvements included a Threat Early-Warning (TEW) operating mode and more automatic signal-parameter measurement. (V)2 was updated to include many of the features of (V)4 Mod 1. Later a new submarine version was introduced, designated (V)1; the (V)2 version is installed on board *Los Angeles*-class submarines (550 MHz–20 GHz). (V)5 is for Trident submarines.

After the cancellation of the surface-ship versions, the submarine versions remained in production. A typical current unit price is \$541,000 in FY90. The first submarine version was approved for service use in 1973. Of the surface types, 3 (V)4 were made before cancellation: only 1 for shipboard, for the carrier

Enterprise. GTE is prime contractor, with an ARGOSystems receiver and IBM improvements.

◆ WLR-9

WLR-9 is an acoustic intercept system; see the ASW section.

◆ WLR-10

WLR-10 is a radar-warning system. In its (V)1 version, it consists of a tuner assembly (4 tuners) and a receiver-processor. Each transmission received is converted to audio intelligence data, primarily monitored and recorded on magnetic tape. WLR-10 shares a periscope antenna with WLR-8.

◆ WLR-13

WLR-13 is an IR/EO-warning receiver.

◆ WLR-14/WJ 1140

This Watkins-Johnson automatic signal-acquisition and processing system for submarine electronic-intelligence collection is a version of the company's WJ 1140. WJ 1140 uses a series of parallel tuners to cover the frequency bands 0.5–1, 1–2, 2–4, 4–8, 8–12, and 12–18 GHz, and coverage can be extended down to 40–550 MHz and up to 18–40 GHz. The associated antenna systems are L-4/A/RS-160 (40–550 MHz), L-6/A, and L-5/A (18–40 GHz). L5/A consists of fixed horns looking up into a spinning reflector. L-6/A is a spinning-horn antenna in a radome, scanning at 0–2000 rpm; the antennas can also be manually steered from the control console. They have a relatively broad pattern and are circularly polarized. The system also employs conical omnidirectional antennas. WJ 1140 can employ a C-204 analysis control unit (ACU), which measures signal parameters and identifies signals automatically, based on time of arrival (TOA), amplitude, pulse width, and angle of arrival (AOA). ACU tuner modes include fixed, band scan, limit scan, and sector scan. The ACU can automatically scan through the tuners at either an automatic scan rate or under operator control. Displays include pulse-by-pulse and average PRI formats, which can be used to determine the detailed characteristics of a signal consisting of a multiple pulse train, such as a phase-coded pulse-compression signal.

WJ 1140 is reported to have been installed on board the Ko-

The Korean destroyer *Jeong Buk* is reportedly equipped with the WJ 1140 signal-collection system (the commercial version of WLR-14), presumably using the directional HF antennas visible here above the usual U.S.-type ESM radomes. (*Sea Power*)

rean destroyer *Jeong Buk*, presumably replacing the earlier U.S.-supplied WLR-1, and using much the same antennas (a pair of lower-frequency antennas has been added). This system is presumably used for radar ELINT. Compared to later versions of WLR-1, WJ 1140 lacks automated signal analysis, but some additional processors may have been added. The later Watkins-Johnson receivers all are automated for signal analysis, as is WLR-1H.

Watkins-Johnson produced a series of later multituner receivers to replace WJ 1140; WJ 1240, 1440, and 1740. WJ 1440 in particular has had naval application. WJ 1240, which covers 0.03–40 GHz, has independent digital control and parallel displays for its bank of tuners, for simultaneous surveillance of several channels. WJ 1440 was derived from WJ 1740; it has microprocessor-controlled memory scan, allowing the operator to store up to 16 scan-control matrixes, the controlling computer automatically scanning through any preselected series of them. A tuner-integrated local-oscillator synchronizer (TILOS) improves overall stability and frequency accuracy.

The current successor to WJ 1140 is WJ 36500 (which is currently under naval contract for testing although it has been built to commercial specification). WJ 36500 (SIRS, signals intelligence receiving system) is a 15-channel superhet receiver covering 30 MHz–40 GHz (although it can be extended to higher frequencies). It can be provided with a DF antenna and can be used for ELINT with a monitor or tape recorder or processor. It has multiple interactive operator stations, using a 1553B bus (LAN) to distribute signals to a variety of tuners, chosen according to application. Such an architecture makes tuner replacement relatively simple, compared to the redesign required in the unbussed systems of the past.

◆ WSQ-5

The Watkins-Johnson carry-on ELINT system for *Los Angeles*-class submarines covers the range from UHF up to mm-wave. This automated system reduces the workload, and presumably the volume, of those it replaces. That is important, since a *Los Angeles* probably has less free internal volume than a long-hulled *Sturgeon*, a type that had been enlarged specifically to make room for a new electronic reconnaissance system, and that is likely to be retired in the near future. WSQ-5, a multioperator system, includes a signals-acquisition system, automated interaction with a series of superhet tuners, signal processors, a means of automatic emitter identification, and automatic data logging and storage (with capability to monitor an advanced tape recorder). WSQ-5 uses distributed 80386-based processors on an LAN. Work on the advanced development model began about 1986, and several have been delivered. WSQ-5 *does not* replace WLR-8/WLR-1H, which are basically threat warners with little or no ELINT capability.

◆ Mk 105 (Target Acquisition Console)/ALR-76

In the mid-1970s selected destroyers and missile frigates were modified to fire Standard ARM antiship missiles. A target-acquisition console Mk 105 made by IBM was added to their WDS Mk 4. The console, which was connected to a version of the ALR-47 airborne ESM set, provided automatic detection, classification, and processing of targets detected passively. Under operator control, ALR-47 passed data to the ship's FCS to preset the Standard ARM antiship missile. Predecessor of the current ALR-76 of the S-3 Viking, the modified ALR-47 had a 4-channel, digitally tuned, superhet receiver. It was fed by an array of 8 cavity-backed spirals. The associated signal-processing computer was an IBM System 4/Pi type SP-0A with 2 memories (total capacity up to 24 kwords). Mk 105 was used primarily against pulse radars. It was selected early in 1972, and 2 were delivered that November for installation on board the 2 prototype Standard ARM ships, the fast gunboats *Grand Rapids* and *Douglas*. In November 1973 IBM received a further contract for 12 production Mk 105s for DDGs and FFGs. Mk 105 may also have been supplied to the Korean navy, which operates Standard ARM on board 3 *Paek Ku*-class missile boats.

The Canadian navy added ALR-76, the successor to ALR-47, to the 3 ships it sent to the Persian Gulf in 1990. It may be the standard means of targeting planned for Harpoon aboard the new "City"-class frigates. The ALR-76 installation is presumably equivalent to the earlier U.S. Mk 105 (but with a more powerful computer).

◆ AEWS

The Advanced Electronic Warfare System was conceived as an add-on to the existing SLQ-32. Work at NRL began about 1978, with Norden as hardware contractor. AEWS is now at the full-scale-development stage; the competitors are Hughes, Norden, and Raytheon.

AEWS is presumably largely or entirely the anti-monopulse-radar concept mentioned in declassified descriptions of the current naval R&D program.

◆ AIEWS

The advanced integrated EW system is a projected successor to SLQ-32.

◆ LAIR

Lamp-augmented IR is a shipboard IR jammer developed by Loral under NRL contract. LAIR is an enlarged and repackaged equivalent of the company's airborne IR jammers. It is now (September 1990) in the advanced development stage. A system of this sort is needed when threat missiles improve in sophistication to the point at which they can distinguish flares. That occurred relatively early for aircraft since missiles could distinguish flares by their motion relative to the real target. For ships, the key development is probably an inexpensive 2-color or 2-tone IR seeker, which can in effect measure the temperature of the flare. NRL interest in an IR jammer would seem to imply that such seekers are now close to entering service. Several Soviet antiship missiles have IR variants or use IR-radar seekers, and there is also the Norwegian Penguin. LAIR was demonstrated during the summer of 1990.

About 1984 Loral supplied an aircraft-type IR countermeasure to protect the yacht of a foreign head of state, perhaps Brunei, from weapons such as SA-7s.

◆ SLEWS

The Shipboard Lightweight Electronic Warfare System is for small combatants and auxiliaries. It is envisaged as a simple modular and expandable system, a nondevelopmental item (i.e., essentially an existing system). An RFI (request for information) was issued in July 1990, and the formal RFP was expected in December 1990 or January 1991. As of the fall of 1990, 80 are to enter service between 1992 and 1997, in 2 versions, 50 for smaller ships and 30 for larger ones. SLEWS originated in the navy's dissatisfaction with the ALR-66(V)6 on board 2 PHMs, and it will equip the PHMs as well as many auxiliaries. Like ALR-66(V)6, SLEWS still retains some requirement for precision DF for missile targeting (probably an accuracy of about 2 deg). Because SLEWS is to be nondevelopmental, foreign companies were invited to bid. Presumably, the RFP will be issued to a reduced list of those answering the RFI. Each company will be asked to provide 1 system to the navy for a 3-month test, at its own expense (a similar procedure was recently followed in the case of electro-optical sensors), using navy-supplied test data. As of September 1990, foreign bidders included Elisra (probably teamed with Loral), MEL (teamed with Westinghouse, offering Sceptre 0), Racal, and the Taiwan Development Corporation. Raytheon probably intends to offer a version of ALQ-142. General Instruments is also bidding. The bids will probably include a firm price commitment so that the ultimate choice can be made on the basis of both cost and performance.

◆ EWCM

Electronic-Warfare Coordination Module is part of the new carrier and large combatant command/control system. It supports the OTC and the EW coordinator. EWCM requires a Twin Data

Bus (TDB) supporting a controlled LAN to segregate compartmented data (SCI, i.e., sensitive electronic intelligence) from normal classified data (GENSER data). EWCM is to use off-the-shelf equipment as much as possible. The core portion includes the TDB. Phase I develops the EW/C3CM software, and Phase II is to incorporate state-of-the-art technical advances. EWCM is intended to work with the TFCC, which is to be fully operational by FY92. As of 1988, 28 operational EWCM were planned, for the carriers, the LHDs, the LCCs, and shore sites.

◆ APECS

Advanced Programmable Electronic Countermeasures System is a multibeam integrated ESM/ECM system that gives elevation and azimuth data on each pulse by monopulse techniques. The phased-array transmitter antennas (2 modules per system, port and starboard) can engage multiple targets simultaneously. This system, manufactured by ARGOSystems, is light enough for installation on fast patrol boats.

◆ APECS-II

APECS-II is a surface-ship EW (ESM and ECM) system for ships displacing up to 8000 tons. In 1988 APECS-II was in production for 4 navies. It employs a phased-array multibeam (16-target) antenna covering 360 deg in azimuth and up to 30 deg in elevation, with high radiated power both in pulse and in CW modes. Compared to older phased-array designs, APECS has polarization diversity (to counter monopulse threats), is easier to install (because it requires neither external waveguide nor water cooling), and can handle complex signals. For example, it can deal with frequency/PRF-agile seekers by tracking the leading edges of their pulses, not waiting until the full pulse has been received before sending the countering signals. Frequency coverage is 0.5–18 GHz.

The ESM portion of the system is the AR-700 receiver, including an upgraded version of the ASP-32 signal processor. The

An ARGOSystems ESM antenna (probably Phoenix II) on board a Korean *Ulsan*-class frigate, with a Radamec HWK 409-029 electro-optical director visible behind it, and an Emerlec-30 mount below. Similar radomes can be seen on board Colombian FS 1500-type frigates, Finnish *Helsinki*-class fast attack boats, New Zealand *Leander*-class frigates, and Swedish *Stockholm* and *Spica-II* classes. (*Sea Power*)

APECS II on board the Pakistani destroyer *Tughril*. (Sea Power)

Passive elements of the ARGOSystems APECS-II EW system for surface ships: 2 low-band ESM arrays (with their omni antennas for IFM) and a radome enclosing the higher-frequency monopulse array, with its IFMs at the top. (ARGOSystems)

ECM portion is controlled by a multiprocessor-driven power-management unit and radiates from 2 stabilized transmitters. Because control is software-based, ECM tactics can be tailored to specific threats. The 2 basic operating modes are transponder (in which the appropriate response signal is preset) and deception (in which the response signal is constructed in response to the details of the received signal). The 2 techniques can be run in sequence, and the entire system can operate fully automatically, semiautomatically (the command to radiate is under operator control, but everything else is automated), or manually.

This system is manufactured by ARGOSystems.

The first APECS II was delivered in 1986. The II/AR-700 suite will be carried on board the new Portuguese MEKO frigates, and APECS II was selected in 1987 for the Dutch *Karel Doorman* class, in place of a more expensive Signaal system.

◆ ARGO 680/681

This system is found on board some Taiwanese (GOC) destroyers. This system employs a single mechanically scanned D/F antenna to cover the E-J-bands. ARGO 680/681 uses electronically scanned antennas for frequency fixing, which is much faster than with WLR-1.

◆ AR-700-S5

AR-700-S5 is an ESM system for submarines that provides threat warning, surveillance, and targeting information using signals in the 2–18-GHz band. DF is by monopulse rather than by a rotating antenna, and the system is also wide open in frequency, using paralleled digital IFM receivers. Bearing accuracy is 5 deg (rms). The embedded signal processor, an ARGOSys-

ARGOSystems miniaturized ESM antenna for submarines. (ARGOSystems)

tems ASP-32, can track up to 200 signals simultaneously, identifying them by reference to a library. The system's frequency range can be extended to 40 GHz.

A miniaturized version of the mast assembly, 6.5 in in diameter and 11.8 in high, has been developed.

This system is manufactured by ARGOSystems.

◆ CAROL

ARGOSystems's intercept receiver and deception transmitter is designed for the new Swedish *Göteborg*-class missile corvettes.

◆ DCJSS

Tracor's Direct-Coupled Jamming/Surveillance System covers the communications bands (100–500 MHz). It couples 2 monitor receivers directly to two 400-W jammers (each containing a receiver, exciter, and transmitter). The system is intended for ship, air, and ground use and can be expanded to 14 monitors (to cover 2–1100 MHz), up to 10 receiver/exciter combinations, up to 10 high-power amplifiers, and direction-finders. DCJSS was derived from a training system; as of 1989 it was under U.S. Navy evaluation and was reportedly the subject of a NATO order.

◆ Digital ESM Receiver (DESM)

This is an Anaren DF receiver, a component of the Rascal Cutlass B1 and reportedly also of a version of the Signaal Rapids. The receiver occupies a radome; a complete 7.5–18-GHz array has a diameter of less than 10 cm. Anaren claims that these small dimensions reduce vulnerability to multipath.

DESM covers the 2–18-GHz range in 2 bands, 2–7.5 GHz and 7.5–18 GHz. It employs a 32-element circular array feeding a Butler Matrix, followed by a phase-comparison receiver. The Butler Matrix produces phase shifts at its outputs proportional to integer multiples of the angle of arrival. Five channels are used: one (1×) with a phase shift equal to the angle of arrival, one with a phase shift equal to twice (2×), one to 4×, and one to 8× the angle of arrival; they are compared to a reference channel. The 8× channel provides the most precise information, but it is ambiguous because every 45-deg shift in angle of arrival produces the same result. The other channels resolve this ambiguity. Thus the masthead unit requires only 5 amplifier channels in each band. From top to bottom, the masthead unit consists of a band 2 antenna, a band 2 matrix, a band 1 antenna, and a band 1 matrix, with the amplifiers and other electronics below in the flared bottom of the radome.

Each pulse is represented as a 55-bit word giving frequency, bearing, amplitude, pulse width, and time of arrival. Bearing accuracy is less than 2 deg, and elevation coverage is +40/–10 deg. Good directional accuracy makes it possible to use angle of arrival as a parameter in de-interleaving trains of pulses, and 2 deg is the level of precision needed for missile launching.

Minimum acceptable pulse width is 200 nanosec in the 2–7.5-GHz band and 100 nanosec in the 7.5–18-GHz band; bearing resolution is 1.4 deg (8 bits), pulse width resolution is 25 nanosec (12 bits), and time of arrival resolution is 1 microsec (16 bits).

The masthead unit is 60 cm in diameter × 101 cm and weighs 60 kg.

The device was publicly described in 1982, by which time it was already in production. The Butler Matrix technique was publicly described in 1980.

As of September 1990, Anaren was considering downsizing the DESM antenna for submarine installation and was also considering a frequency extension down to 0.5 GHz.

◆ EW-100/200/300

These threat-warning suites are designed for fast patrol boats. EW-100 is the basic system; EW-200 is improved; EW-300 is an integrated suite. All provide 360-deg cover in azimuth and 60 deg in elevation, are based on a 16-bit programmable computer with 1-sec reaction time, and have a library of 75–100 emitters. EW-300 weighs 300 lb and covers the D–J-bands.

These systems are manufactured by Loral.

◆ FERRET

An austere submarine ESM set by GTE, FERRET uses an Israeli front end and covers the entire 1–40-GHz band. The narrow-band subsystem (1–18 GHz) uses up to 4 superheterodyne receivers for precise analysis. Claimed DF accuracy is 5–10 deg. Frequency resolution is 125 kHz (narrow-band) and 5 MHz (broad-band).

◆ GUARDIAN STAR

Sperry Marine's automatic ESM direction-finder (ADF/ESM) is for small patrol combatants. The Mk 3(V) version, announced in 1987, combines omnidirectional and monopulse DF antennas (6 spirals) with an RF digital frequency-discrimination (DFD) unit. Guardian Star is interesting as an example of the capabilities that are possible using modern high-density electronics with distributed (rather than concentrated) microprocessors.

The antenna, with its radome, is 36 cm high and 15 cm in diameter (14 × 5.9 in) and weighs 5 kg. The associated digital interface unit weighs 33.5 kg. The display is a 48-cm-diagonal raster-scan color unit. The system as a whole illustrates the high density of modern electronics. The digital unit converts each received pulse or CW signal into digital form. The display sits atop a processor that sorts pulses and compares them with library entries. Output can include platform identification and threat-level determination based on library matching. Sperry describes the library (containing 1000 emitter modes) as uniquely structured for ease of automatic identification; the operator can load the library with specific emitter characteristics, or the load can be from some separate electronic data base. The operator has a scratch library with a capacity of 50 emitters.

The display is normally a polar plot (emitter frequency vs. bearing), but because the display is digital it can also show emitter frequency vs. amplitude. Typically the display also provides tabular data on particular emitters (e.g., name if identified, bearing/confidence level of bearing determination, frequency/amplitude, PRF/pulse modulation, scan rate/threat level, and platform/use if library matched). The operator interacts with the display by means of a touch screen and a keyboard.

The system covers frequencies 2–18 GHz (frequencies are determined within 7.5 MHz), PRFs 100–300 kHz (determined to within 0.002%), pulse widths 0.1–100 microsec (measured to within 0.05 microsec), and scan rates 16 msec–40 sec (deter-

Guardian Star Mk 3(V). (Sperry)

mined within 10%). Elevation coverage is within a 30-deg cone. Sensitivity is -60 dBm across the entire bandwidth. Claimed false-alarm rate is less than 1 per hr, and the manufacturer claims a probability of detection greater than 99% (Sperry claims a probability of intercept of unity if 6 successive pulses are received). The system can track 250 emitters simultaneously. Emitter throughput is less than 1 sec, and the display is updated 50 times/sec. Sperry claims a bearing accuracy of 10 deg for 2–8 GHz, and 5 deg for 8–18 GHz.

Sperry offers several optional extensions. The frequency range can be extended down to 0.5 GHz and up to 40 GHz. Frequency precision can be improved. The system can be extended to receive communications (VLF through UHF). Guardian Star can be connected to control chaff and flare launchers and to correlate with a radar; Guardian Star can also be modified to estimate target range by target-motion analysis (analogous to submarine ranging by TMA).

Guardian Star is based on the electronically scanned ESM antenna of the U.S. Type 18 periscope, on *Sturgeon*- and the new *Seawolf*-class submarines. In this application it has no specific designation, and it uses standard military processors, etc. The display is the one Sperry developed for its anticollision shipboard radar.

Guardian Star has been ordered for retrofitting to Venezuelan *Lupos*.

◆ Locator 1000/2000

Locator is General Instruments's modification of ALR-66(V)3 for shipboard self-protection. Because it includes a user-generated threat library, Locator can be used to trigger defensive measures such as chaff launching. Like ALR-66(V)3, Locator incorporates a precision direction-finder and covers the C–J-bands. There is an automatic mode for minimum manning; in a large ship, an operator can change the priority assignment of different signals, display emitter data, and analyze selected intercepted signals.

Locator 1000 is a new-generation export system that uses much the same antennas (at least the same radomes) as ALR-66(V)6. Locator 1000 employs a directional antenna (87 lb, 26.1-in diameter $\times$ 16 in), a pair of fixed antenna receiver enclosures (FARE, 40 lb each), a frequency measurement unit (FMU), and an ESM console. Frequency coverage is E–J-bands, with C/D optional; DF accuracy is better than 3 deg. MTBF is 1000 hr, and MTTR is about 30 min. Locator 1000 is designed to support OTH-T but also provides threat warning for a separate ECM system. The console incorporates a plasma touch display showing both polar and tabular emitter data. General Instruments describes the system as a unique combination of wide-band receivers, parallel DF channels, and multiple processors. Presumably, the reference to parallel channels means a combination of relatively imprecise monopulse DF (for contin-

Locator 1000 array, with the DF antenna in the dome at the center, probably on board a *Pegasus*-class hydrofoil. (General Instruments)

Locator 2000 DF antenna and jammer antennas, with the console. (General Instruments)

uous signal tracking) and a directional antenna (e.g., for targeting). Locator includes pulse-analysis capability.

Locator 2000, for larger ships, can incorporate a jammer using a multibeam array transmitter, which uses repeater and transponder techniques (e.g., range-gate stealing). The high-resolution color display is controlled by keyboard and trackball; it shows emitter data in both polar and tabular form. The ESM portion of the system matches that in Locator 1000, except that the console is larger (presumably with greater computer capacity). The ECM portion consists of 2 semi-omni antennas (6 lb, 7.5-in diameter), 2 multibeam array transmitters (MBAT, 490 lb each, 30.7 in wide $\times$ 34.5 in high $\times$ 32.4 in), an ECM rack (570 lb), and a repeater/switch (82 lb). ESM performance matches that of Locator 1000. The optional ECM system can deal with up to 16 simultaneous threats, at frequencies of 7.5–18 GHz, with ERP up to 86 dBm.

Unlike their competitors, these systems do not incorporate separate IFM channels. In a conventional digital ESM system, the IFM and monopulse DF channels operate separately, each producing output words. The processor must then match IFM pulse data to directional words to characterize each pulse. General Instruments uses a proprietary fast IFM, matching frequency and direction on a pulse-by-pulse basis, thereby avoiding the correlation problem.

◆ MEWS

Hughes's Modular EW System was based on SLQ-31, the unsuccessful alternative to Raytheon's SLQ-32; MEWS was the basis of the current Taiwanese navy Chang Feng III. All of these systems use the antennas of the larger SLQ-17, such as the slotted waveguide inside a nearly semihemispherical reflector (a multiple-feed parabolic torus). Hughes liked this particular design because it provided stronger beams on the broadside, where the ship's cross section is greater and, therefore, where more jamming power is needed to overcome reflections from that cross section.

For Hughes, the key to cost control was provision for capability growth without excessive additional system expansion. Hughes placed particular emphasis on anticipating possible threat growth and change since some elements of the system (such as antennas) could not be expected to change inexpensively. For example, a system initially designed to deal with sea-skimmers might later face steep divers. The beam generated by a linear array, which might be quite effective at low angles, might spread out at higher angles of elevation, and a more complex antenna with better beam control at higher elevation might, therefore, be preferable.

Within the signal processor, Hughes sought growth potential by using microprocessors in parallel. Increased system capability would be achieved by adding more of these parallel channels, each on a circuit board, and each fitting into a slot provided

when the original less-capable system was manufactured. For example, signals would be de-interleaved by microprocessor PRI trackers, each responsible for 1 train of pulses. Given this architecture, the system would add the ability to track more targets by adding more trackers. In a typical system, incoming signals would be split up in a power divider, which would direct them into signal-processing channels. Each channel consisted of a frequency filter and 4 PRI trackers, and the total system might be able to accommodate up to 6 channels and thus up to 24 trackers, i.e., 24 simultaneous target signals.

A published description of MEWS logic (1982) showed the application of these ideas to a typical antenna, a multiple-feed parabolic torus like the ones used in SLQ-17. This type of antenna uses a series of ports to form beams; the beam is moved by switching the signal generator among the ports. Such an antenna might be designed with 10 feeds to produce 10 high-gain beams. On the other hand, the feeds might initially be paired to produce 5 lower-gain beams, at a lower cost in electronics. In the example given (which probably does not precisely correspond to MEWS), two 4-port electronic switches were used, 1 feeding 3 ports and also the second switch. The second switch fed the other 2 ports, 2 of its outlets being unused. In an expanded version of the array, each of the 2 original switches would feed 4 ports, and a third switch would be added to feed 2 more. The 10 original beams would have been 20 deg wide (10 deg for the 2 pointing abeam), compared to 40 deg (20 deg for the 1 beam pointing abeam) for the simpler version.

The full 10-beam version could be further expanded by adding a fourth 4-port switch and using 3 of its outlets and the 2 previously unused outlets of the third switch to drive a second series of beams elevated above those of the 10-beam array, doubling elevation coverage by forming four 40-deg beams and one 20-deg beam. This growth would be possible by allowing for additional torus antennas in the system radome, additional cable runs, and additional switches and their driver cards. Because the improvements are preplanned, and because they use hardware identical to that already in the system, this growth should be relatively inexpensive.

A Hughes diagram of a typical EW system shows masthead arrays for reception in 2 bands. One array consists of 2 receivers, each at a 45-deg angle to the centerline, at each end of a yard. The array below it appears to use 4 receiving antennas, 2 side by side pointed broadside and 2 more angled out from the central pair. In this version, the typical Hughes box antenna, with its 2 angled sides and its flat side pointed broadside, is used for transmission (presumably it does include ECM receiving antennas for beam direction). On the other hand, Hughes's description of MEWS offers antenna options ranging from rotating high-gain horns to fixed switched arrays.

In 1984, with MEWS presumably in production for Taiwan, Hughes claimed ESM coverage of 2–18 GHz with a sensitivity of –60 dBm and dynamic range of 60 dB. DF accuracy was 5 deg (monopulse), with 1 deg available using a precision dish. Elevation coverage was 0–15 deg (using the stabilized boxes), and the library carried 1024 emitter modes (with 256 emitters in an active environment file). Reaction time was 1 sec or less. The ECM portion of the system could operate over 7.5–18 GHz, with a sensitivity of –70 dBm, and it could handle 40 simultaneous threats. Deception modes were listed as sequences and combinations of RGPO, countdown, swept audio, noise cover, and false targets; the system could also produce spot, swept, and barrage noise. Reaction time was listed as 1 sec or less.

The version illustrated in the 1984 brochure employed masthead receiving antennas (with both monopulse and dish elements) and stabilized boxes for transmission. Photographs of a Taiwanese navy Wu-Jinn III destroyer, fitted with Chang Feng III, show a single radome near the 2 transmitter boxes. There is also a small foremast radome, probably a TACAN.

◆ PHOENIX II

ARGOSystems's ESM/DF system (1–18 GHz in 5 bands) is for ships of fast-patrol-boat size and larger. Announced in 1984,

PHOENIX II was ordered for the Colombian HDW corvettes and the Indian Type 1500 submarines, among others. PHOENIX II uses a combination of omnidirectional, monopulse, and directional antennas and IFM receivers. All signal processing and identification is automatic.

Phoenix IV is a fully automatic version.

◆ PMTS

Passive Multitarget Tracking System is Anaren's new precision direction-finder, proposed for the NAAWS system. Angle accuracy is to within 0.2 deg, and the system can track in azimuth and elevation to within 0.5 deg. Tracks can be reported within 2 sec of detection, and 10 targets can be tracked simultaneously, the system operating in TWS mode. A land-mobile version has 2–5-MHz frequency accuracy, and DF accuracy is within 0.8–0.2 deg, depending on frequency. Total antenna beamwidth in this version is 2–13 deg, and the system covers 2–18 GHz in azimuth and 3.8–18 GHz in elevation.

The standard version uses a pair of interferometers in 1 reflector, which forms the overall 2.5×60 -deg beam. The azimuth array extends horizontally across the top of the reflector. It breaks the 2.5-deg horizontal beamwidth into 32 beams, each 0.09 deg wide. The elevation array forms 2 beams, the 2.5×60 -deg beam and a 2.5×2.5 -deg "deck" beam used to overcome multipath effects because its beams tend not to intersect the horizon. The main 60-deg high beam is broken into 512 elements, each 0.09 deg wide. The deck beam is broken into 32 elements, each also 0.09 deg wide.

PMTS also incorporates a new technique that uses relative phase to determine whether an intercepted signal comes from the side- or main lobe of the target.

PMTS was tested by the U.S. Navy in 1989; it demonstrated its ability to track low-lying targets over water. Anaren has proposed PMTS for other applications, such as the U.S. Air Force TR-1 battlefield-surveillance airplane. As of September 1990, sea trials were scheduled for the fall of 1991.

In mid-1990 Anaren began to develop its PMTS technology for application to an active radar, providing limited 3D capability by adding an interferometer array to the top of the conventional 2D antenna. An operator would obtain altitude data on a target designated by azimuth or by a range bin. The additional electronics would be installed on the antenna pedestal, with minimal synchronization with the receiver. Elevation data would be provided for a subset of the target tracks.

◆ S3000

S3000 is EM Systems's surveillance system for submarines. S3000 is installed in British *Oberon*-class and nuclear submarines. S3000 uses a high-gain scanning antenna plus an omnidirectional antenna and IFM receiver; the operator selects scanning, sector-scan, or pointing modes for the directional antenna. There is an associated threat library and an automatic threat-alarm feature. Coverage is 0.5–18 GHz.

◆ Sea Sentry

Kollmorgen's ESM system for submarines and surface ships was announced in 1980. Versions I and II are for surface ships, with version III for submarines. The basic system covers the 1–18-GHz range, with automatic detection and DF (accuracy better than 10 deg). A 150 MHz–1 GHz receiver is available as an option so that all communications bands can be covered. Sea Sentry I is a simple ESM system to support fire control in fast attack craft. Sea Sentry II is more sensitive and can incorporate an IFM or superheterodyne receiver. Sea Sentry III is designed for full integration with a submarine's combat system, using both the periscope and its own antenna (multiple arrays and microwave receivers on a mast). The General Instruments DF/threat processor has a 128-emitter threat library, and it can be supplemented by additional ELINT information collected by the Sea Sentry III system. Up to 35 emitters can be processed simultaneously, and 15 displayed. The user assigns a priority to each threat radar, CW (fire-control) radars having the highest.

Threat surveillance is automatic, and there are 2 modes: (i) surveillance, as a wide-open receiver providing all-around cover; and (ii) search, in which frequency is measured and direction is more accurately measured. The system measures both CW and pulse signals, displaying threat identity, bearing range, and other signal data on its CRT. DF accuracy is about 10 deg.

Kollmorgen claims that Sea Sentry III (Model 962U) is the first completely automatic broad-band radar-threat detection-and-analysis system integrated into a submarine's surveillance periscope. Sea Sentry III detects and identifies signals in the 100 kHz–1 GHz range and detects, determines the bearing of, and identifies signals in the 1–18-GHz range. The antenna consists of 3 omni and 4 DF spirals that collectively receive 100 kHz–18 GHz signals. The LF omni units are a voltage probe antenna; a top-loaded electric-field probe connected to an impedance-matching transistor amplifier, housed within a dielectric radome on top of the array; a sleeve/stub, a thick quarter-wave monopole above a ground plane around the spiral antennas and receiver components; and a biconical omni housed within the dielectric radome below the VPA. The 4 DF spirals are identical and mounted spatially around the cylinder to provide 360-deg coverage in 90-deg segments. Four identical microwave receiver channels are housed within the antenna array, each receiver fed by 1 of the DF antennas. A 4-digit LED readout displays the threat's center frequency, within 15 MHz; threat characteristics are presented on a radar-parameter digital display.

Although only 1 version is for submarines, Sea Sentry is intended primarily for a submarine's use; Kollmorgen is a periscope maker. Argentina bought Sea Sentry III for its TR 1700 submarines, and India bought both the system and the company's periscope.

◆ Series 800

This is a mobile and shipborne communications-surveillance and DF system, operating over 3 alternative frequency ranges (1.6–30 MHz, 1.6–180 MHz, and 1.6 MHz–1 GHz) and incorporating an automatic single-station location (SSL) system. In the sky-wave region of the HF spectrum (2–30 MHz), SSL is achieved by vertical triangulation using information about the height of the ionosphere. For higher-frequency signals, the emitter is located by comparing bearings from adjacent directional receivers. The shipboard installation consists of a number of wide-band HF receivers spread around a ship, sampling the currents excited on the ship's structure by an incoming signal, and comparing phases to obtain accurate bearing and elevation angles.

The related Series 810 automatically acquires, analyzes, and catalogs HF signals; it can be set to sort signals and generate alerts for important ones.

The land-based equivalent (Series 400) employs a large circular Wullenweber array antenna, which can be as much as 300 m in diameter, or a series of crossed loops. A land-mobile version employs 9 foldable crossed loops, each 2 m on a side.

Series 800 is manufactured by Technology for Communications International (TCI).

◆ Shields

Raytheon has developed an integrated EW suite, Shields (Ships Highpower Electronic Defense System), for export, using the unique lens-fed MBAT developed for SLQ-32. There are 2 versions, (V)1 for small ships and (V)2 for mid-size ones such as frigates and destroyers. Like SLQ-32, Shields uses its lenses to generate multiple beams simultaneously, each beam having the full gain of the aperture. Using its multiple receiving beams, Shields can detect and track multiple threats simultaneously.

Shields has a separate lens jammer. As in the receiver, the lens is used to form beams by adjusting the relative phases of different signals passed through it. In Shields, the jamming modulation is applied before the low-energy signals are passed through the lens. Each position on the lens surface corresponds to a beam. The lens applies the necessary phases to form beams, and the resulting signals are picked up on the far side of the

Shields (essentially SLQ-32(V)2) and the Sidekick jammer (marked "Shields ECM"). (Raytheon)

lens. Then they are amplified by moderate-power TWTs before transmission. The usual problem of such an electronic beam-forming jammer is high-speed switching of a single high-powered jammer; Shields avoids the problem by providing a moderate-powered jamming transmitter (TWT) for each array element. The separate jammer is probably the Sidekick, which has been adopted by the U.S. Navy as an adjunct to SLQ-32.

Shields was designed, developed, and tested for an unspecified export customer, probably Taiwan. Shields was announced in 1989.

◆ SLR-600 Series

These private-venture ECM systems are made by General Instruments Corporation specifically for fast patrol craft. SLR-600 is an ESM system for fast patrol craft; it is highly automated for ships with small crews. It uses IFM techniques and combines a broad-band (E–J-band: 2–20 GHz) receiver with a fast processor for rapid response. Automation requires the system itself to decide which radars it is detecting: the display shows radar identifications, based on data in the threat library, as well as the details of pulse width, PRF, and scan rate for radars that do not fit the library's information. The operator can select data on any specific radar for readout, and the system provides an alarm if a specific threat radar is detected. SLR-600 responds to tracking radars within 1 sec and to scanning radars within 2.

SLR-600, a navalized version of the ALR-66 RWR, uses a 4-antenna array to measure direction with an accuracy of 15 deg.

SLR-610 is much the same system with expanded frequency coverage (C–J-bands, 6.5–22 GHz) and with a different display (presumably making greater use of the operator).

SLR-640 is an improved SLR-610, adding accurate directional information. The dual CRT display shows both a polar plot of detected signals and a detailed parameter readout on a selected list of detected emitters. ALR-646 is a similar airborne system.

SLQ-630 is a jammer.

SLQ-650 (INEWS, Integrated Naval EW System) is a fully integrated system consisting of an SLR-640 receiver and an SLQ-630 jammer. The monitor shows both the threats being jammed (monitored by the ESM system) and the type and level of jamming. The system can track up to 100 targets continuously, presenting their parameters in tabular form (20 to a page) and also displaying them in polar form. The system automatically selects the highest-priority threats and passes their data to the jammer, which uses a high-gain steerable antenna. Several emitters can be jammed simultaneously: modes include range and angle deception.

PERFORMANCE OF SR-200

	Band 1 (0.5–2.0 GHz)	Band 2 (2.0–4.0 GHz)	Band 3 (4.0–8.0 GHz)	Band 4 (8–18 GHz)
Direction of Arrival accuracy	7.5 deg	5 deg	4 deg	2 deg
Frequency accuracy	9 MHz	9 MHz	17 MHz	21 MHz
PRF range	75–100 Hz	125 Hz–100 kHz	250 Hz–100 kHz	500 Hz–100 kHz
PW range	0.2–100 microsec	0.2–100 microsec	0.1–100 microsec	0.1–100 microsec

Some SLR-600 series systems were exported to an unnamed customer. These systems are no longer in production. The Thai *Ratcharit* class, completed in 1979–80, shows a radome similar to that of the later ALR-66(V)6 on board some of the U.S. *Pegasus* class, so Thailand may be the customer. For a time, SLQ-650 was planned for the *Pegasus* class, but it appears that instead SLR-21 was selected and then ALR-66(V)1.

◆ SR-200

SR-200 is a shipboard ESM receiver with automatic frequency measurement (0.5–18 GHz, with optional extension to 40 GHz). The frequency range is broken down into 4 bands (C/D, E/F, G/H, I/J, with an optional extension into K). This receiver is intended for fast patrol boats and is designed to provide sufficiently accurate DF to support the targeting of antiship missiles. SR-200 is designed to operate in a dense pulse environment. The antenna array consists of an omnidirectional antenna and a rotating multihorn (for multiband) DF antenna. The omnidirectional antenna hands over the signals it intercepts to the DF antenna, which in turn provides signals for analysis. SR-200 provides an alarm based on the identity of an emitter. The display is either a PPI (strokes) or tabular. SR-200 can also be adapted to provide ESM data to a conventional radar display.

To measure direction of arrival, SR-200 uses a rotating antenna with sidelobe blanking. The receivers use wide-open IFM, for rapid intercept and acquisition. Automatic signal processing is employed to achieve rapid identification in a dense environment. The signal processing technique is azimuth-oriented spatial sampling. There are 3 receivers: IFM, TRF (tuned RF), and logarithmic video. Outputs are digitized pulse by pulse. The IFM is fed only by the narrow-beam directional antennas; the other receivers are fed by the omnidirectional antenna (TRF can be either).

The design emphasizes angular accuracy, which is required to estimate the range to a potential target. Range can be obtained by observing the change of bearing angle as the ESM platform moves along a baseline. The system can get within 10% of the range by measuring the bearing angle within 1 deg. For shorter ranges (within radar range), the ESM system can be used to point a ranging radar; accurate pointing permits very short radar transmission and so minimizes the risk of counter-detection.

Parameters: RF, PW, PRI, scan, DF, amplitude
Capacity: 500,000 pps, can display 58 active tracks

As measured in 1980, the system's performance was typically better than 2 deg on a single pass, and better than 1 deg on multiple passes. The accuracy above is measured at 1000 PRF. In a test in August 1980, SR-200 outperformed the requirements listed above. At 1 GHz, the requirement was 10 deg, but the system achieved an accuracy of about 3 deg; at 3 GHz the requirement was 5 deg, but the system was actually accurate to about 1 deg. At 6 GHz the measured accuracy was about 2 deg (the same at about 2 GHz); at 13 GHz it was about 1 deg (requirement was 2 deg).

SR-200 is manufactured by Sanders Associates. Sales: 8 to Peru (for FBPs) and 11 to another unnamed customer. SR-200B (baseband) was sold for land use.

◆ WJ 8957 (SCANS)

The Watkins-Johnson signal collection-and-analysis system is applicable to ships and submarines.

◆ WJ 8958 (DFS)

The Watkins-Johnson shipboard DF systems (0.5–2 GHz) for ships and submarines are currently in service both in the United States and abroad but are not as yet assigned any official U.S. nomenclature.

◆ WJ 32500

WJ 32500 is a ship or submarine ELINT signal-collection system (0.5–12 GHz, covering the COMINT and ELINT bands). Typically, it has 5 operator positions: 3 for COMINT (Morse or HF, voice/VHF/UHF, and special signals in HF-SHF), 1 for telemetry, and 1 for ELINT. It requires 9 racks of electronic equipment.

◆ WJ 34901

The Watkins-Johnson DF antenna, covering 2 MHz–2 GHz, uses loops and monopoles to achieve an accuracy of better than 3 deg within a radome 16 in wide and less than 31 in high. It can be used by both surface ships and submarines. This antenna is under navy contract, but it has not yet been delivered.

EXPENDABLES

◆ Mk 33/34 Launcher (RBOC)

RBOC was the Hycor Rapid-Blooming-Chaff launching system. Mk 33 was for frigates or destroyers (4 launchers); Mk 34, for corvettes, fast patrol boats, or hydrofoils (2 launchers). The launcher itself is Mk 135. This system has now been replaced in U.S. service by Mk 36, but it was exported. These launchers

Loading a Mk 33 RBOC. (U.S. Navy)

were either automatically or semiautomatically controlled by the ship's ESM system. Each launcher was a 6-barreled mortar fixed in position: the barrel elevation angles were 55, 65, and 75 deg (by pairs). The standard Mk 171 chaff cartridge provided short-range protection, to about 150 yd (slant range). For longer ranges (about 1000–1500 yd), a rocket motor could be added to the cartridge.

Decoys included chaff (2–20-GHz range), an IR decoy (HIRAM), and a combined decoy (Gemini, a parachute-suspended flare).

In 1977 a typical cartridge outfit for two 6-barrel launchers was 32 Mk 171 and 16 HIRAM (IR) decoys, plus 2 Mk 173 test cartridges.

Loral (Hycor) continued to market RBOC and to produce improved rounds, such as LOROC, for the 4.4-in RBOC after the U.S. Navy shifted to the 5.1-in SRBOC launcher. Its RBOC II launcher has been sold to foreign navies for small warships.

The burst of a Gemini combined IR/chaff decoy. The chaff streamers blow apart, while the IR flare descends slowly on a parachute. (Hycor)

A Gemini decoy. (Hycor)

◆ Mk 36 SRBOC

The Super Rapid-Blooming-Chaff launcher fires 130-mm cartridges. Mod 1 with two 6-tube launchers is for ships under 140 m; Mod 2 with 4 launchers, for ships over 140 m. All use Mk 182 chaff-dispensing cartridges, which climb to 244 m. A "Torch" IR decoy is being developed for use with Mk 36 SRBOC, and the NATO Sea Gnat rocket chaff dispenser may be adopted. Cartridge types are Super Chaffstar, Super Hiram III/Super Hiram IV (IR), and Super Gemini RF/IR.

Mk 36 SRBOC launcher. Versions exist with the tubes either splayed, as here, or in rows of 2. (Hycor)

A Super Chaffstar decoy for SRBOC. (Hycor)

◆ AEB

The U.S. Navy's Active Expendable Buoy is similar in size to an A-size sonobuoy and contains a receiver, power supply, TWT, programmable signal processor, and deployable antenna. In June 1984 Dalmo Victor received a contract for 45 test buoys. Operational evaluation was completed in FY87, and a cost-reduction program began in FY88. AEB is deployed from aircraft or ships. This buoy counters enemy command/control; an advanced multipurpose buoy, now under development, will counter surveillance and targeting radars and missile seekers into the 1990s.

◆ AED

AED is the U.S. Navy's Active Expendable Decoy.

◆ ARM Decoys

In September 1989 it was reported that projected ARM decoy systems for several radars had been canceled: those planned for SPS-39A, -48, and -52, and for SPN-6, -35, and -43A. No decoy had been planned for SPY-1. Presumably, these decoys would have been projected from standard chaff launchers. These reports were made in the context of an OSD report on new Soviet antiradar missiles. It is not clear why the cancellation of ARM decoys for obsolete or obsolescent radars (such as SPS-39A and SPN-6 and -35) radars excited much comment. It would seem, too, that the ship-simulating active decoys would have an anti-ARM effect since they presumably emit signals similar to those of standard combatant radars.

◆ CAD

CAD is a ship-fired radar simulator, made by Brunswick Defense. CAD hangs from a parachute and mimics the emissions from search radars. The program was jointly funded by the air force (for land application) and the navy, but funding was suspended just as the program was about to enter full-scale engineering development, about 1987.

◆ HIRAM

Hycor's IR Anti-Missile decoy for RBOC launching (112 × 117 mm, 4.1 kg) is a floating (spar buoy) IR decoy, sufficiently bright to duplicate the radiant intensity of even a large ship. HIRAM-2 (8 × 35 in, 29.4 lb; the decoy extends beyond the mortar's muzzle, and the portion in the mortar is of 112-mm diameter) uses liquid (similar to JP-5) rather than solid fuel, to burn longer (1 min rather than 0.5 min) with a brighter and higher flame (3 m high), to protect against IR missiles seeking their targets in either of the 2 typically used wavelength ranges (windows). HIRAM-2 will strike the water about 150 m from a ship in 5–7 sec. HIRAM was announced in 1980, for deployment in 1981.

HIRAM IV decoy (with "IR" marking). (Hycor)

◆ LODED

NRL's project for a Long-Duration Expendable Decoy was announced in the early 1980s. LODED was a slow-flying aircraft, planned for an endurance of 12 hr and a payload of 40 lb. Only a scale model, slightly over half scale, was built. It had tandem wings and a pusher propeller. It had no tail as such: the forward wings pivoted together for pitch control, and the after wings pivoted separately for roll control and together for pitch trim. The power plant was a 1-HP 2-stroke engine driving a 2-blade propeller. Dimensions: span 5 ft 8 in × length 4 ft 1 in, maximum body width 6.75 in, propeller diameter 11 in. Weight: 25 lb loaded (8-lb fuel, 10-lb payload). Launch speed was 33 kt. This project is interesting as an example of the way an RPV can be used for a ship's protection.

◆ TORCH

TORCH is a replacement for the earlier SOID. A quick-reaction off-board IR decoy launched by SRBOC, TORCH burns while floating on the water.

◆ Standard U.S. Chaff Cartridges

The first U.S. chaff cartridge, the Mk 76 Chaffroc, was fired by Zuni (5-in) rocket, using a modified aircraft launching pod. Its 10-kg payload was burst open by a time fuze, at up to 15-km range. The theoretical cross section was 60,000 m², but because all the chaff was released at one point, the effective cross section was 1000–2000 m². Mk 76 was in service in 1965–69.

Mk 76 was succeeded by the Hycor Mk 84 (1969–71); it used new packaging and deployment technique. About a third more chaff was carried, and it was in hundreds of packages (cassettes), that rapidly bloomed in patterns 100 m in diameter. Total radar cross section was about 3 times that of Mk 76. However, Mk 84 was expensive; only about a third of its weight went into chaff; it was too large for a small ship; a separate jammer (ULQ-1) was needed to shift the missile tracker from ship to chaff cloud; and chaff deployment/track transfer took too long.

The next step was a mortar with a seduction round, RBOC (Rapid-Blooming Off-board Chaff) Mk 171 (1972–74). Hycor delivered the first 11 sets of Mk 33 mortars early in 1972. Mk 171 carried much more chaff, using a new plastic-film wrap to sub-

Chaff packaged in an early decoy: Mk 84. (Hycor)

Chaffstar I decoy (with "RF" marking). (Hycor)

divide the load. The initial mortars were delivered to the fleet off Vietnam and were, therefore, called Westpac. The developed version, Mk 171, entered service in 1974. Radar cross section was about 7 times that of Mk 76. Mk 171 could be made for any frequency from 2–20 GHz. Mk 173 is a reusable inert test cartridge. Hycor markets Mk 171 as Chaffstar.

Mk 171 was intended to protect destroyers; and a new round, Mk 182 (Super RBOC, 130 mm rather than 112 mm), entered service in 1977. SRBOC carries about 4 times the payload of Mk 171, in 2 stages (macrocassettes for first-stage deployment, and plastic wraps within each macrocassette for second-stage deployment). Radar cross section is about 13 times that of Mk 76. Mk 182 is currently the standard U.S. chaff round.

The next stage is Mk 214, development of which was completed in 1986. Mk 214 provides about 26 times the radar cross section of the original Mk 76.

At present the U.S. Navy uses only chaff mortars; there are no chaff rockets. In the past, and probably still, there were also 5-in chaff rounds. The major chaff rocket program, Chafroc, was canceled in 1974 because of technical difficulties. However, as decoys become heavier and more elaborate, deck reaction in the existing mortars grows and becomes less acceptable; it seems likely that rockets will return in the near future.

◆ ALEX

A shipboard decoy (chaff or IR) system made by Hycor, ALEX is available in 2 calibers (130.2- and 112.8-mm) and with 2–20 launchers that have automatic round selection and sequencing. ALEX can use all current U.S. Navy cartridges, as well as the Chaffstar, Gemini, HIRAM, and LOROC series.

◆ Chaffstar II

Announced in 1986, Hycor's chaff cartridge produces a much larger chaff cloud than Chaffstar (Mk 171). Chaffstar II is much longer than Chaffstar (112.3 × 1067 mm, 18.2 kg vs. 112.3 × 412.1 mm, 4.15 kg) and, therefore, must be launched from an RBOC II launcher with barrel extenders. Muzzle velocity is 200 ft/sec, and the typical cloud is 328 ft [100 m] in diameter, with an area of 7850 m². Payload weight is 8.2 kg [18 lb].

◆ LOROC

Hycor's long-range off-board countermeasures chaff decoy can be launched from a lengthened RBOC II launcher and has an additional booster rocket. LOROC is launched to burst 1.0–4.5 km away from the ship for distraction. Dimensions: 112 × 1200 mm, weight 14.75 kg, payload weight 2.3 kg.

This round outranges the only current U.S. Navy chaff rocket, Sea Gnat Mk 216 (maximum range is reportedly 1.5–2.0 km). The U.S. Navy abandoned its long-range chaff-rocket program in 1974 because of technical problems, and by the late 1970s all surviving chaff rockets (adapted Zuni aircraft rockets) had been landed. LOROC has been exported to several foreign navies. It cannot be adopted by the U.S. Navy because the United States no longer uses the 4.4-in-caliber mortar.

LOROC chaff decoy. (Hycor)

A typical CIC control panel for chaff launchers. This system is CAMLAC, by Hycor, controlling two 6-barrel launchers that are loaded, in this case, with a mix of RBOCs and LOROCs. (Hycor)

A typical bridge control panel for chaff launchers, in this case the Hycor CAMLAC. There are 2 launchers, and the lower set of buttons indicates that control is being exercised from CIC rather than from the bridge. (Hycor)

ANTISUBMARINE WARFARE

Antisubmarine warfare is carried out by 3 almost distinct forces: long-range maritime-patrol aircraft, which are cued by underwater surveillance systems or other very long range intelligence; surface ships, which may themselves launch helicopters (or cue aircraft); and submarines on patrol in likely areas of enemy submarine concentration, which rely largely on passive sonars and on long-range heavy torpedoes.

At this writing, the only ASW sensors effective beyond a few hundred yards are acoustic. Numerous (and expensive) attempts to develop nonacoustic sensors have not succeeded, except under very specialized conditions; and there is every evidence that the world's navies must continue to rely on acoustics. Non-acoustics is attractive because, at least in theory, a nonacoustic sensor can be operated continuously by an airplane or even a satellite. Acoustic sensing demands that the sensing platform put something in the water, either an expendable sonobuoy or a hull or towed sonar. Because sonobuoy fields must be of limited size and density, an airplane's search rate is inherently limited. In addition, the finite supply of sonobuoys always limits possible searches.

Generally there is a surface layer in the sea, kept at constant temperature (hence constant sound velocity) by mixing due to weather; this surface layer acts as a waveguide. The surface layer is about 300–600 ft deep in the North Atlantic, for example, depending on weather conditions. Within this layer, sonar acts much like radar, with signals propagating in nearly straight lines.

Below the layer, the velocity of sound varies with the depth, so rays of sound tend to bend, just as light passing through a complex medium will be refracted. One effect of this bending is to limit drastically the detection range of a surface ship against a submarine below the surface layer. For a hull-mounted sonar, the maximum (direct-path) range in the surface layer is about 20,000 yd, and ranges are often considerably shorter. Whether a given sonar can realize such maximum performance depends upon the sonar's power and frequency.

If the sonar's signals can propagate far enough, and if the water is deep enough, they bend down to a region of minimum sound velocity and then refract back up. The signals focus in a convergence zone around the ship, at a range set by water conditions. The convergence zone forms an annular ring around the ship, and additional convergence zones form at multiples of this first range. The typical range to the first convergence zone in the North Atlantic, for example, is 35 nm, and additional zones are found at 70, 105, 140, etc. Each zone may be 5 nm wide, and the sonar detecting a submarine in a convergence zone cannot distinguish positions within that zone. As a result, weapons cannot be fired on the basis of very long range detection. Instead, some platform must search the area in the zone within which the submarine may be located, to reacquire the target before attacking.

Two other acoustic paths deserve mention here. One is bottom (or surface) bounce: both the bottom and the surface can function as acoustic mirrors. In the late 1950s it appeared that bottom-bounce propagation could help fill the gap between relatively short direct-path ranges and long convergence-zone ranges; maximum bottom-bounce range was about 40,000 yd. Bottom bounce later lost much of its popularity because the sea bottom in much of the world turned out to be much more absorptive than had been expected.

A submerged submarine (or, in theory, a submerged variable-depth sonar) can use surface-bounce propagation. Presumably, U.S. submarine sonars are spherical (i.e., can both depress and elevate their beams) specifically to exploit surface- as well as bottom-bounce propagation. Soviet submarines, such as Victors, have bow torpedo tubes and are presumably, therefore, limited to chin sonars, which are unlikely to make much effective use of surface-bounce propagation. That limitation in turn may be related to an emphasis on operation at shallow depths. Surface-bounce propagation is somewhat limited by weather, since reflection will be much less efficient if the surface is rough on the scale of sonar wavelengths, i.e., several feet.

Undersea warfare is complicated because sound does not travel in straight lines. It is, therefore, important to be able to predict that path. This display is a sonar ray-path predictor; the sound velocity profile is at left, and the corresponding prediction is at the right, for a sonar deep in the water. There is a combination of convergence zone refraction and reflection off the surface. (Thomson Sintra)

Typical sonar transmission patterns are shown on a ray-path predictor. All are from submerged sonars (variable-depth sonar or a submarine). At top, the rays bounce off the surface and curve around because of the convergence-zone phenomenon. The middle picture shows the effect of refraction in bending sonar rays up and down; this effect is the convergence-zone phenomenon. The bottom picture shows rays trapped in the surface duct at top, and bouncing off both the surface and the bottom. Whether a ray is trapped depends on the angle with which it is projected. (Signaal)

Both bounce paths are inherently limited in range because the sound ray must pass steeply enough through the various layers to avoid refraction and trapping, a phenomenon equivalent to that of the critical angle in optics. Actual range must depend on the bottom depth (or, in the case of surface-bounce, on the depth of the source), but for surface ships under average conditions the usual assumed maximum range is 40,000 yd. That figure may be based in part on an estimate of the loss to be expected in reflection off the bottom.

The other alternative is the reliable acoustic path (RAP), essentially the vertical path from bottom to surface or vice versa. No matter what the acoustic layering of the sea, a signal propagated perpendicular to the layers should pass through without distortion. There should also be a small angle around the vertical in which signals can pass with little loss or distortion. If the sound source or detector is deep enough, even that small angle can subtend a very considerable distance at the surface. RAP is hardly new, as it explains the successful operation of echo-sounders. However, the widespread application of RAP to sonar operation is relatively recent because an RAP sonar generally has to be quite deep.

In relatively shallow water, inside the 100-fathom (600-ft) curve, convergence-zone propagation is impossible. Hull sonars suffer from multiple bottom bounces, so detecting real targets is very difficult. However, a very high frequency upward-looking RAP sonar can function effectively. A sonar source well below the surface, moreover, can send out a horizontal beam that can avoid bouncing off either bottom or surface. Horizontal transmission is probably one mode of operation of the new low-frequency helicopter dipping sonars.

Sonar may be active or passive. Active operation has the advantage of imposing a signature on a submarine, and thus of overcoming silencing; but active operation reveals the presence of the searcher, and range is limited by the amount of energy that can be poured into the water. Passive operation depends upon picking up relatively faint sounds against the background of a relatively noisy ocean. When passive signals can be picked up, extraordinary ranges can be achieved because of multiple convergence zones. In most cases, success with passive sonar has been the key to NATO's ASW dominance, with active operation virtually limited to homing torpedoes. That situation may now be changing.

The major development of the past few years has been the Soviets' progress in countering Western sonars. Countermeasures consist of both silencing submarine noises to reduce pas-

Given knowledge of the possible sound paths, sonar performance can be predicted. This typical modern display has the sound-velocity profile at left. Maximum effective range, read out at right, is 20,000 yd, and maximum target depth is 1400 m (limited by refraction). (Thomson Sintra)

ive ranges and applying anechoic coatings to absorb active signals and, thus, to make active detection more difficult. The anechoic coatings cannot be very thick, so they are likely to be most effective against relatively high frequency sonars, i.e., against the sonars on board homing torpedoes.

The basis of passive operation, i.e., of all signal processing, is that the submarine's signals are regular, whereas the background noise is random. There are 2 fundamental approaches: the signal may be analyzed in spectral (frequency) terms, on the theory that over time the constant signature of the submarine will emerge; or the sonar can look instead at small volumes (cells) of ocean, choosing a particular cell that is consistently louder than its neighbors on the assumption that it contains a noise source. Mathematically, the 2 approaches are Fourier-transform alternatives. Spatial processing (i.e., concentration on a cell or on a volume defined in terms of bearing angle) is equivalent to adding up (integrating) signals over a broad band of frequencies from sources within that cell or angular range. Spatial processing is, therefore, often described as broad-band. The alternative (spectral processing) is, naturally, described as narrow-band.

Narrow-band noise is produced by rotating devices such as machinery and propellers or, for a diesel, the regular firing of the engine. In practice, each line of noise is accompanied by harmonics, weaker repetitions of the sound at progressively higher frequencies. A signal processor may concentrate on a harmonic, even though it is weaker, because it occurs in a quieter part of the background noise. Moreover, because listening arrays are limited in size, they will have better gain (i.e., better discrimination in direction) at higher frequencies. The better that discrimination, the less background noise is mixed with the signal of interest.

Broad-band noise is much less well defined. Examples might include the flow noise over the submarine's hull and the gurgling of piping inside the submarine.

The appropriate choice for analysis depends on several factors. The fainter the submarine's sounds (i.e., the better it is silenced), the longer the period of integration required to separate a regular acoustic signature from the surrounding noise. If the signature is not really constant, integration time is limited, perhaps below what would be required to overcome noise. In that case broad-band (spatial) processing may be a much better choice.

Many systems combine the 2 types of analysis, forming beams (i.e., processing spatially) and then breaking down the signal in each beam by narrow-band processing. The greater the computing power of the system as a whole, the more easily it can conduct this 2-step analysis. Given sufficient processing power, the user must cope with an enormous amount of data; typically, then, the user needs some semiautomated means to indicate the presence of a real signal in a narrow frequency band of 1 of many beams.

Conversely, a computer-based combat system can track an enormous number of targets simultaneously. There will generally be relatively few real ones, but analysis of the motion of the others will often allow them to be disregarded. This is also true of decoys, and it explains the need for a modern torpedo, such as Murene, to track numerous targets simultaneously.

To deal with quieter and more distant targets, arrays have grown in complexity and in area; in one typical case, the number of separate hydrophones (in several arrays on board a submarine) quadrupled. Since all the array data is digital, it can all be processed together, a single system forming beams out of all the array data. This type of processing can be very powerful (for example, it can form nulls to cancel out self-noise and jamming), but it also entails a very high data rate, in this case more than an order of magnitude greater than in the past. This output in turn is needed to improve resolution, both in space and in frequency space, to detect quiet targets more effectively amid the surrounding noise. The associated system has over 200 channels of track information: 12 passive broad-band trackers, 2 DEMON trackers, 4 adjustable spectral window trackers, 8

passive-ranging trackers, 5 active track channels, and 164 high-quality automatic trackers. Such numbers would overwhelm an operator at a display; the system must make many of the decisions as to how the targets it detects are to be tracked, the operator monitoring the process and intervening when necessary.

Both types of processing can be quite sophisticated, and both represent alternatives to active operation. After World War II, when submarines (particularly those snorkeling) were relatively loud, passive operation entailed essentially no integration: a sonobuoy (or, for that matter, a homing torpedo) had only to seek a noise noticeably louder than its surroundings. That operation was very simple broad-band processing. That era ended in the early 1950s, as submariners learned not to snorkel for protracted periods. The question then was whether passive ASW was still practical. The solution turned out to be low-frequency narrow-band processing and integration, which the U.S. Navy code-named LOFAR (Low-Frequency Analysis and Recording).

LOFAR was the basis for Western passive acoustics from the mid-1950s on, and for many years it was a closely guarded secret. The success of LOFAR depended in part upon knowledge of the detailed acoustic signatures of potential enemy submarines because signal processing could be much more effective if specific features of a target submarine's acoustics were known. During the 1970s Soviet recording devices began to turn up in areas where NATO submarines operated, such as Norway and Puget Sound. Such devices are useful only in a LOFAR-acoustics context. In 1988 the U.S. DoD provided confirmation by publishing a photograph of a Soviet equivalent of a U.S. LOFAR sonobuoy.

Many modern passive sonars use waterfall displays, in which the vertical ordinate is time. The horizontal scale is either frequency or bearing. In either case, the data flow down from the

LOFAR was the most important ASW discovery of the first postwar decade. Here the upper 4 bands are LOFARgrams, and the targets are visible as the brighter lines amid the noise. Below the LOFARgrams are A-scans in which the total strength of each frequency interval is shown. All of the displays show the same real data, but the different LOFARgrams represent different integration periods. The longer the integration time (i.e., the greater the time represented by the vertical scale), the brighter a steady line will be. On the other hand, a line that is steady for a time but then fades out (e.g., because the submarine alters her behavior) will vanish over a long integration period. Thus some lines that are fairly clear in some of the LOFARgrams vanish in others. The different A-scans use different exponential integration periods. All of the LOFARgrams look grainy because this is a CRT display rather than a copy of a paper printout. Parameters are shown at the bottom, and also at the top and bottom of the displays. A similar display could be used to show data from several sonobuoys simultaneously, or to show different frequency ranges (in an attempt to match up harmonics of the same line). The original of this photograph is in color, and different colors are used to distinguish the different processing times used. (GEC-MUSL)

In many cases, an airplane will monitor several sonobuoys simultaneously. Here a LOFARgram and its corresponding A-scan are shown top and center, and another LOFARgram (with several prominent lines) is shown at bottom. The peak in the A-scan corresponds to the bright line in the LOFARgram at top, but the line is much more visible. The center display is automatic line integration (ALI); many modern passive systems automatically detect signals whose integrals pass through some preset threshold. An alert operator might well have seen the line in question long before ALI caught it. Moreover, ALI might well miss the bright lines at bottom, which change in frequency over time. In both LOFARgrams the latest time is at the top. The cross is a cursor used to read out the frequency of the line it is placed over; the corresponding data (465 Hz, 2.979 dB) read out at the top. (GEC-MUSL)

top of the display, which shows the short-term history of what the sensor receives. The beaming version, therefore, shows relative target motion. Signals that are constant in frequency stand out in a frequency waterfall (a LOFARgram, often shortened to "gram"). The observer integrates the data visually to separate the stable signals (which appear as more or less continuous vertical lines) from the surrounding noise. The LOFARgram is, in effect, a spectrogram. Some systems record relative intensities at different frequencies at time intervals and then integrate over time to form a true spectrogram that is usable, for example, for automatic or semiautomatic target recognition.

The original grams were paper records equivalent, in theory, to waterfalls. The new signal appeared across the top of the paper and moved down as the paper moved. Marks on the paper indicated the intensity of the signals picked up at various frequencies. The electronic form of a gram shows signals over only a short period; the associated system generally relies on its memory to pick up long-term but weak signals. A paper gram can be spread out and integrated, in effect, by eye, and sometimes that is superior to the mathematical analysis. For example, a line varying slightly (e.g., due to doppler) can be picked up by eye. Some current systems provide both CRT and paper readout specifically so that signals missed on the CRT will be picked up when the paper gram is spread out.

The hard-copy printer is inherently limited by the speed at which a record can be written, usually 1.25 sec/line. Hence the paper recorder must show signals as they are processed and, thus, cannot easily switch from channel to channel. A CRT can rapidly switch, so it can show all the historical data in the processor. The CRT can simultaneously display several portions of a frequency spectrum to emphasize harmonic relationships between lines. This technique is specially valuable in deciding whether particular lines are related to submarine speed or to machinery gear ratios. The CRT can also be used to designate a particular line to the system to begin, e.g., a tracking or bearing measurement algorithm. Hard copy, however, is more useful to regain a lost contact since the operator's eye can bridge a vertical gap in a line, whereas a gap may break the computer's track.

Waterfalls are not suitable for active sonar displays since a waterfall cannot show range and bearing simultaneously. Therefore, active scanning sonars generally use PPIs. In cases of ODT transmission, the display often uses an expanding ring to represent the outgoing minidirectional pulse; in contrast, in a radar PPI, a line representing the directional pulse and its echo revolves around the face of the scope. Many active sonars use B-scans, rectangular displays of range (vertical) vs. bearing. Compared with a PPI, a B-scan has the advantages of compressing distant targets into a limited space yet showing nearby targets clearly. Searchlight sonars use an A-scope and bearing indicator.

This view is a passive-detection display of a Thomson Sintra sonar; the original is in color. At any one time the spectrum can be integrated to provide a graph showing the directions from which the loudest noises come (as at the top of the display). These lines are not quite like the lines of the usual waterfall, showing more gradation. The bottom of the display shows these integrals as they have changed over time, to indicate target maneuvers. The result is like a waterfall but more finely graded. (Thomson Sintra)

As a submarine maneuvers, a nearby target changes bearing. The change can be used to measure the target's range. Modern computer-assisted submarine combat systems do this target-motion analysis automatically, sensing changes in own-submarine course and speed. This Thomson Sintra passive-ranging display shows the assumed target path at top and the own-submarine maneuver at bottom; the graph at the bottom shows how target bearing has changed during the maneuver. The ranging algorithm assumes that the target is following a steady (but unknown) course. The upper right-hand corner indicates that the operator can choose instead passive ranging by triangulation or active ranging. Target-motion analysis requires time: the longer the analysis, the better the range accuracy. Modern computer-aided systems tend to be much faster than older manual plots, using essentially the same techniques. (Thomson Sintra)

Armed with knowledge of the primary Western signal-processing technique, and probably driven by revelations of the effectiveness of NATO's detections of submarines, the Soviets have been able to achieve considerable silencing in their latest classes. The question, again, is whether passive signal processing has much of a future.

Three possibilities emerge, and as yet it is impossible to choose between them. One is that improvements in LOFAR technology—e.g., by adding more spatial discrimination, by tightening discrimination between nearby frequencies, or just by increasing integration time—can solve the problem. The United States' new LOFAR array sonobuoys and continued investment in towed passive arrays typify this approach. If this approach succeeds, the current situation, that Soviet submarines can be detected at long range without revealing the presence of NATO forces, will basically continue.

Another possibility is that low-frequency narrow-band passive sonar will lose its capability, so that passive operation will be reduced to medium-frequency flow noises. In that case, it will pay to abandon expensive signal processing in favor of mass producing relatively simple (broad-band) sensors of flow noise and strewing them about the estimated position of a submarine. This approach would seem to be the basis of the new low-cost sonobuoy. An intermediate possibility would be to distinguish regular features of broad-band noise and, thus, to retain longer-range operation at a cost in processing complexity.

LOFARgram concepts are also applied to towed and other passive arrays. This is a typical towed-array classification display. The upper gram is narrow-band. In the next, the frequency scale is expanded (wide-band) to show many more lines than those above. In the 2 Vernier displays below, the frequency of the line of interest (T32) can be measured more precisely because the entire scale is quite narrow. Each line is assigned a track number so that the associated computer tracker can perform MA on it. The heading of the array (which is not the heading of the ship towing it) is read out; that is the function of 1 of the modules in the array. (GEC-MUSL)

Two methods of broad-band classification are shown. At top, demodulated noise (DEMON) is represented in LOFARgram form (a single line is visible). At bottom, these data are shown in correlogram form. This is a type of waterfall display, the broad areas showing several targets maneuvering over time. The towed array floats above the submarine towing it so as not to foul her propeller. (GEC-MUSL)

The third alternative is to abandon passive operation in favor of very low frequency, i.e., very long range, active operation. In that case the existing low-frequency systems would be retained, but they would function as the receivers in bistatic sonars, receiving echoes from the pings of relatively simple noise sources. Several active towed arrays, described in these pages, typify this approach.

Driving the development of ASW weapons, sensors, and tactics are the basic facts of sonar operation: sound propagates farthest at low frequency, and sound tends not to propagate in straight lines. Lower frequency means longer wavelength, and a sonar operating at that lower frequency must be larger to maintain the same gain (directionality). World War II sonars operated at high frequency (20–30 kHz) to assure directionality even with relatively small transducers. Medium frequency might loosely be defined as the range 5–15 kHz, and low frequency as about 1–5 kHz. However, some navies regard 5–7 kHz as low frequency and so describe their sonars. Operation below about 1 kHz generally requires devices, such as towed arrays, different enough from conventional sonars for another differentiation to be made, e.g., very low frequency. Another way to draw this distinction would be to associate high frequency with short direct path ranges and with sonars essentially limited to the surface layer. Medium-frequency sonars can detect submarines below the (surface) layer at useful ranges, and, if properly designed, they can use the bottom-bounce path. Low frequency means convergence-zone propagation, at least potentially. On this basis 5 kHz is low frequency in the Mediterranean, but about 3 or 3.5 kHz is required for low-frequency operation in the Atlantic and the Norwegian Sea. The history of sonar since 1945–50 has been a series of jumps down in frequency and, therefore, up in range. The velocity of sound in water is about 4700 ft/sec, so 30 kHz equates to a wavelength of about 1.8 in. A typical World War II maximum operational

as a very broad range of frequency responses. A single unit of the array may be long enough to provide good directionality for signals at the highest frequency (i.e., shortest wavelength) with which the system deals. That unit becomes the middle subunit of a second, longer subarray used at a lower frequency. Typically, all the subarrays are built of identical basic units, so in this case the second subarray is 3 times the length of the first, operating at a third of the first's base frequency. The 2 are nested, the units of the first subarray working simultaneously at both frequency ranges. Forming the middle of the lower-frequency array, the first is said to nest in the second. Adding 2 more units to the ends of the 3-unit array gives a third array 5 times the length of the first, operating at a fifth its frequency.

If the first subarray was designed to work in the range around 500 kHz, the second would be centered on 200 kHz and the third on 120 kHz. The U.S. SQR-18A reportedly consists of 8 identical subunits, 2 of which form the highest-frequency subarray. The combination of those 2 with the 2 at their ends forms the next lower-frequency subarray (at half the highest frequency). If the next 2 are counted, then the next-lower subarray consists of 6 basic units, at one-third the highest frequency. All 8 basic units form the lowest-frequency receiver, working at a base frequency a quarter that of the highest-frequency subarray.

In each case, the subarray is imagined as built out fore and aft from the center of the array as a whole. That design greatly simplifies beam-forming. Beams are formed by adding the outputs of the subelements of the subarrays in proper phase, and that addition changes least from frequency to frequency when the array is handled symmetrically.

Current towed arrays are passive receivers of sounds made by submarines; but as the submarines become quieter, it becomes attractive to provide an active sound source, generally in the form of a flex-tensional transducer operating at about 150–600 Hz (wavelength about 7.5–30 ft). The array would then act as the receiver of a very low frequency sonar.

Systems vary from navy to navy partly because different navies operate under very different acoustic conditions, and partly because navies perceive their missions very differently. For example, the Royal Navy operates its frigate-towed arrays largely for surveillance. They must, therefore, be relatively long (to work at the low frequencies at which sound propagates most effectively); and the ships must be very carefully silenced. In contrast, the U.S. Navy operates separate surveillance arrays (the SURTASS program) and separate tactical arrays, the latter for defending battle groups or convoys. U.S. tactical arrays can, therefore, be shorter, and they can tolerate worse acoustic conditions.

Sea conditions modify sonar choices. In summer, the surface layer in the Mediterranean, for example, may be only about 50 ft deep, so hull-mounted sonars become nearly useless. That condition explains the long-standing interest of the French and Italian navies in variable-depth sonars, which can operate under the layer. In the Mediterranean, too, the deep sound-channel is much shallower than in the Atlantic, and the convergence zone is much closer. In consequence, there is little point in using very low frequency sonars, and neither the French nor the Italians have gone as far as the U.S. Navy in the development of lower-frequency sonars. Other warm areas, such as the Arabian Sea, also have shallow surface layers, heated by the sun and often not mixed with deeper, cooler water. The Baltic is notorious. Because so many rivers empty into that sea, its acoustics are dominated by alternating layers of different salinity, from which sonar pings reflect. That condition is 1 reason the Swedish navy effectively abandoned ASW in the 1960s, and also 1 reason why it has been so difficult to determine whether the Soviets really are operating midget submarines in shallow Swedish waters. On the other hand, the Arctic Ocean is at a nearly constant temperature, so that the surface layer extends down to the bottom, making for very much longer effective ranges. Presumably, the only problem is the reflection and refraction of sound in the presence of large masses of ice. Special sound conditions may also be caused by particular marine life

or particularly heavy shipping lanes or fishing areas. Other special conditions obtain in other areas, such as the South China Sea or the waters around Australia, and these conditions help explain why different navies have adopted such different approaches to essentially the same sonar technologies.

Some technological points require explanation. Virtually all modern sonars scan. They may send out directional pings, but they do not wait for the ping to return before looking in another direction. Reception is separated from transmission because the sonar can receive in all directions, either in quick sequence (with a scanning cycle much shorter than the ping's length, so that the sonar is in effect looking in all directions all the time) or actually simultaneously. Because the sonar need not continue to stare in 1 direction before looking elsewhere, the scanning rate is independent of the expected time between ping and echo (i.e., independent of range), and a sonar can search a large volume with a reasonable probability of detecting a target.

A scanning sonar consists of an array of more or less omnidirectional transducers, achieving directionality by combining the signals from several adjacent transducers in the appropriate phase relationship, much as a phased-array radar works. This idea is not new: as long ago as World War I, linear hydrophone arrays formed beams using delay lines (which were sometimes called "artificial" or "electrical" water because the lines corresponded to effective water paths to different elements of the array).

Scanning sonar was developed in parallel by the United States, Britain, and Germany during World War II. In older U.S. (and many other) scanning sonars, a commutator carrying the appropriate (beam-forming) phase relationship scans physically. Each transducer stave feeds a stator element, and the commutator (rotor) spins within this external stator to form a series of successive listening beams that, in effect, sample the returning echoes. The listening beam must scan quickly enough to pick up at least part of the echo from any target within range, so the emitted pulse should be about as long as the time for any single scan. The shorter the pulse, the faster the scan must be. For example, a pulse 33 msec long would be associated with a scanning rate of 1800 rpm.

The usual display for such a sonar is a radar-like PPI, in which the point of light indicating a possible target describes a spiral, sweeping simultaneously around and outward at a rate proportional to the local speed of sound. Sometimes a circle indicating the outward motion of the omnidirectional ping is superimposed.

Similarly, the transmitting beam can be rotated by a second stator within which another rotor spins. Each transducer stave is connected to 1 stator pole in an oscillator programmer (in U.S. terminology) in the sonar control room. The scanner rotor turns continuously and is energized only when the sonar transmits. It in turn energizes the stator poles and, thus, forms the rotating beam. The faster the rotor speed, the shorter the pulse, since each stator is energized for a shorter time. The rotor carries low-energy signals that are amplified between stator and transducer stave.

It might seem simpler to spin a commutator within the transducer itself, but the separate stator arrangement makes it possible to provide 1 or more additional beams that need not turn continuously. The main examples are a tracking beam using left-right comparison and a separate audio beam, which the sonar operator can place atop a target of interest. The audio beam picks up target sound for classification; at least until very recently audio was the chief means of target identification. The U.S. SQS-4 and SQS-23 series have separate video (continuously scanning) and audio beams. ASPECT (see below), a sonar echo technique, was 1 attempt to find an alternative means of target classification.

This scanning system was used in SQS-4, -23, and -26. The use of an external rotor later extended to the big spherical bow sonars used in submarines, such as BQS-6.

The commutator has several disadvantages. It inevitably adds to the noise of the system. Because it samples all the transducer

outputs, it cannot listen continuously; therefore, it misses some transient sounds. It also cannot fully exploit the strength of a long pulse since it will be listening in the appropriate direction for only part of the received pulse. Finally, the mechanically scanned system is really most appropriate to a cylindrical (or, in modified form, a spherical) sonar since the commutator must treat every group of adjacent staves alike. In a sonar transducer without such symmetry, the same transducers require different delays or phases to form beams pointing in different directions.

The parallel British approach was to provide appropriate networks of delay lines from groups of transducers to form separate beam patterns simultaneously (the prototype used 72 elements and formed 72 beams). Each beam was provided with a separate amplifier and rectifier, the charge on the rectifier representing the strength of the signal from the direction in which that particular beam was pointed. It, therefore, stored the whole of the returning ping. The array of 72 rectifiers could be scanned periodically. This arrangement was more complex than the U.S. commutator, but it could be applied relatively easily to shapes other than a simple cylinder. On the other hand, scanning rate was unrelated to ping length, and the sonar could get the full benefit of each ping. The wartime British set was scanned 1000 times/sec, equivalent to a range of 2500 yd.

This British system could be called beam preforming, and it was more closely analogous to radar technology than was the U.S. system. In theory, different groups of staves could be activated to produce the desired beams, and the beam could scan in some random pattern. The British verdict was that the faster scanning possible with preformed beams allowed for better contact-keeping. Moreover, because such a sonar could be other than cylindrical, it could concentrate sonar energy (and listening capability) on a narrower sector, for greater range. This view led to the development of the flat-plate Type 177. To the extent that the Soviet spy rings at Portsmouth were obtaining uniquely British sonar technology in the mid- to late-1950s, they were presumably obtaining the sector-scan/preformed-beam technology of Type 177.

The wartime German GHG passive submarine sonar (which led postwar to most of the major Western passive submarine sonars, and probably also to Soviet types) was broadly analogous to the British scanner, with a network of delay lines (compensators, also sometimes called "artificial water") to form its beams. Typically, a compensator switch was combined with a series of delay lines. Turned into a position corresponding to a given beam direction, the compensator switch sampled only certain hydrophone outputs and fed them through the appropriate delay lines.

Modern sonars use preformed beams, which make better use of the entire transducer array than any commutator system. Unlike the British wartime and postwar sets, however, they are not hard-wired, and they do not scan through the outputs of the beams. Instead, the beam-forming phase relationships are stored electronically. Individual transducer outputs are digitized, and beams are formed arithmetically, these outputs being added and subtracted with the appropriate multipliers. The sonar signal processor can then deal with all of the beams simultaneously. In effect, the sonar stares in all directions at once. This type of processing explains the very high computing power required in modern sonars.

Such digital operation is called DIMUS (digital multibeam steering) or beam preforming. Beam preforming is clearly easiest for a symmetrical sonar but can also work for a more complex shape, such as that of a conformal array. In any case it has the great advantage of making full use of the arriving signal, eliminating scanning loss. In addition, the relationships between outputs from the different transducers can be adjusted to meet changing operational or water conditions (adaptive beam-forming) since the relationships may be software-controlled rather than hard-wired. Thus, beam-forming is a prerequisite for building complex conformal sonar arrays.

Beam-forming can also be used to project or to receive multiple beams, just as a phased-array radar can produce several

beams simultaneously. A commutator sonar requires a separate commutator for each such beam. Physically, beam-forming generally involves the replacement of a mechanical commutator by a digitizer and the associated digital computer(s). The effect is greatly to increase the number of targets that can be handled simultaneously.

The first scanning sonars sent out omnidirectional pulses (ODT, omnidirectional transmission). These sonars had the advantage of effectively matching their transmissions with omnidirectional reception, but the power available in any 1 direction was limited. One modern alternative is RDT, rotationally directed transmission, the sonar sending out concentrated pulses along each bearing while scanning through all transmission directions, like a 360-deg radar. The drawback to simple RDT is that it does not scan through all directions quickly enough. Some sonars employ tribeam transmission, scanning 3 transmitting beams that are 120 deg apart.

Sonars are sometimes classified as search or attack, or a single sonar may operate in both modes. Attack always implies a narrower beam capable of tracking a target sufficiently well for weapons to be aimed. The required standard of aiming depends on the lethal envelope of the weapon. A mortar or rocket launcher, whose bomb has only a very limited lethal range, generally requires 3D ballistic information, including the underwater equivalent of height-finding. A homing torpedo, delivered either over the side or by rocket or missile, may need little more than an initial range and bearing, although the target's depth may still be important for predicting a target's position.

Most ASW surface ships armed with mortars or rocket launchers in the early postwar period were provided with separate search and attack sonars, and some ships still show this distinction. On these ships, the attack sonar has a narrow beam that can both train and elevate. In more recent sonars, the beam can be depressed electronically, since each vertical stave (an element that resembles and is named after a barrel stave) consists of several fairly nondirectional transducers that can be phased relative to each other. In large sonars the beam can be elevated fairly precisely. However, in a few cases there is only 1 fixed elevation or perhaps 2 alternative elevations. For example, a 24-stave sonar credited with 48 beams probably produces a fan of 24 beams at 1 elevation and 24 at another. It is impossible for any modern stave sonar to depress its beam continuously so as to match the motion of a target precisely.

A few sonars still employ searchlight operation, which was standard through the end of World War II: they concentrate their energy in a single directional pulse and have only a single receiver. They must ping in 1 direction, and listen for an echo, before they shift to another direction. That requirement severely limits the search rate. All specialized attack sonars are searchlights capable of depression.

There is also an intermediate case, a flat-plate sonar that scans a limited sector. Compared to an ODT scanner, the flat-plate sonar provides a stronger ping and may achieve a tighter beam over the scanned sector. Such sector scanning might be justified for a ship operating as 1 of several escorts in a screen.

Many of the sonar entries mention alternative range scales. They equate to alternative pinging rates. As in a radar, a sonar cannot easily distinguish a ping returning from a very distant target (after another has been sent out) from the echo of a nearby object: the problem of the second-time-around echo (STAE). Therefore, a sonar operator will set the ping rate beyond the maximum range he or she expects to achieve. On the other hand, the operator will try to get as many pings as possible, to increase the probability of detection, typically using some type of sonar-performance predictor to set the ping rate.

As in radar, the length of the sonar's pulse determines the precision with which nearby objects can be distinguished. The length of sonar pulses is typically measured in msec (thousandths of a sec), compared to microsec (millionths) for radar pulses.

Many current search sonars can generate very short pulses for a form of target imaging for classification; in the U.S. Navy this

is called ASPECT (acoustic short pulse echo classification technique). ASPECT first appeared about 1960, and was applied to U.S. sonars through the following decade. Several short pulses are sent in rapid succession. Like longer pulses, they are reflected, not by the target as a whole, but mainly by a series of highlights. Because they are very short, the pulses produce separate echoes from the separate highlights (the echoes that longer pulses produce from the different highlights overlap). The combination of short echoes is a sort of target image, and it can indicate both the character of the target (for classification) and even its heading (target aspect, hence the name) relative to the sonar. ASPECT initially used a paper recorder similar to that of LOFARgram; the echoes printed as a series of horizontal lines.

Torpedoes, both antiship and antisubmarine, are listed in this section because so many weapons are dual-purpose. They deserve some comment. Three kinds of torpedo seekers are in current use: active pingers, passive, and wake-followers (or wake-homers). There are also straight-runners, pattern-runners, and command-guided (wire-guided) weapons.

Until World War II, all torpedoes were straight-runners, analogous to artillery shells. In many cases these torpedoes could be turned through an adjustable gyro angle after leaving the tube, but then they ran as straight as possible. Effective range was, therefore, limited by the accuracy of the torpedo and by the ratio of the torpedo's speed to the target's speed. Since the main method of torpedo warning was visual observation of the wake, it was often argued that a wakeless (electric or oxygen) torpedo could be fired at a faster or more distant target, in the expectation that evasive action would not be taken. The main countermeasure to such torpedoes was zig-zagging (whether or not the torpedo was detected), in the hope that the firing platform would be unable to anticipate the target's maneuver.

Straight-runners were generally fired at designated targets. Weapons fired beyond the effective single-target range were said to be fired "into the brown," i.e., into the mass of targets in hopes of hitting 1 (this was also called a "browning shot"). One way to increase the efficacy of such a shot was to program the torpedo to weave back and forth in the mass of target ships until exploding under 1 of them. The most common pattern-runners zig-zagged (the French even designated their pattern-runners in a Z series); but the Germans, Italians, and probably the Soviets produced aerial torpedoes that circled. Pattern-runners are still an economical way of attacking convoys from a safe distance. Wake-following (see below) was conceived as an improvement on simple pattern-running.

The alternative was to provide the torpedo with a homing system so that the weapon could convert a miss (due to firing at excessive range) into a hit. During World War II the Germans developed passive homing torpedoes as antiescort weapons, and

A typical torpedo fire-control display shows target data at the bottom (bearing, range, course, speed) and torpedo parameters at left (gyro angle, attack depth, aim point along the length of the target, the choice of active or passive homing, search depth, the choice of whether to use a proximity [influence] fuze, the enable range of the seeker, the type of launching, and whether the water is deep or shallow). In this case the torpedo is a wire-guided F17, fired against a slow (12-kt) surface target, so the choice is for passive homing and a search depth of 6 m and a proximity fuze. The torpedo is fired at a 140-deg gyro angle: the submarine is almost beam-on to the target. (Thomson Sintra)

the Allies developed much the same technology for ASW. At that time, both submarines and surface ships were loud enough to attract such weapons. Later, however, the development of antiship and antisubmarine torpedoes diverged.

Antiship torpedoes almost have to be passive homers for 2 reasons. First, the water's surface acts as a mirror, and an active homer near the surface can easily be attracted into it. Second, a surface ship does not provide much of an echoing target (distinct from the surrounding surface, that is).

As long as submarines were relatively noisy, it was not too difficult to design a torpedo to home on their loud noise. It is much more difficult to design a torpedo to listen for subtle low-frequency (long-wavelength) sounds, to automatically decide that it is hearing a submarine, and then to steer for the source of that noise. As submarines became quieter, then, torpedo designers had to turn to active operation, incorporating powerful high-frequency sonars in the noses of the weapons. This development was accepted most readily in the United States. Active homing automatically alerts the submarine target, and U.S. designers have assumed that an alerted submarine will run off at maximum speed. They have, therefore, required torpedoes fast enough to catch up, the rule of thumb being that the torpedo must be 50% faster than its target.

Until recently, European torpedo designers preferred what they called a covert approach, homing passively at relatively low speed. They argued that, unless alerted, a submarine commander would generally operate at low speed, and that a relatively slow (and very quiet) torpedo might well catch the submarine unaware. Consequently, many European torpedoes employ inherently quiet electric motors, at the cost of high speed. It now appears that submarines, at least Soviet types, will increasingly be too quiet for the covert approach to work and, therefore, that all future ASW torpedoes will be fast active homers. In turn, torpedo design will be substantially more difficult. This evolution is exemplified by British practice. Tigerfish was a very quiet, relatively slow torpedo. Its successor, Spearfish, is being marketed as the fastest torpedo in the world.

On a more detailed level, the earliest homing torpedoes could be described as using 2- or 4-beam energy comparison (i.e., only left-right or a combination of left-right and up-down). Their signal processors were, in effect, hard-wired. During the 1960s it

Once targets can be tracked automatically, a combat system computer can help evaluate threats as a decision aid. It can also superimpose torpedo operating limits on the display, to show which targets can be engaged. (Thomson Sintra)

became possible to form multiple beams so that the torpedo's view of its surroundings was better defined. As in a shipborne sonar, the narrower the beam, the better the torpedo's ability to reject the noise around a target. In some passive systems (such as the French E14), phase comparison replaced energy comparison. During the 1970s new torpedoes were designed with software-controlled signal processors and seekers and with more sophisticated sonars, which could be doppler-enabled (i.e., which switched tactics depending on the target's velocity) and which could use coded sonar waveforms (to improve the signal-to-noise ratio, perhaps without increasing peak power, thus denying the target longer-range warning). The torpedo's acquisition range defines a cone within which the weapon can locate targets. The longer the range, the greater the band in depth equivalent to the angle of view of the torpedo's seeker. A torpedo with a narrow depth-band must describe a helical search path through the water, whereas 1 with a broader depth-band may be able to search at a single depth. The latter technique reduces the fraction of (limited) torpedo endurance that must be devoted to search, and also reduces the evasion time available to the target.

There is 1 other modern homing technique: wake-following. A surface ship's wake extends many ship's lengths aft, and the wake's boundaries can be detected relatively easily. A torpedo can be programmed to turn through a preset angle each time it crosses the wake, so that it takes a sinuous path toward the ship, around the wake (assuming that the torpedo enters the wake at an acute angle). If the torpedo can detect both wake boundaries, it can run up the wake itself, wasting less time in turning back and forth and, thus, giving itself a better chance of catching a fast target. Wake-following was invented in Germany during World War II (as a variation on pattern-running), and this program has been tried out by most of the major torpedo manufacturers since then (see the Soviet torpedoes and the U.S. Mk 45F). Wake-following has 2 great virtues. First, the wake is so massive a ship's signature that it is difficult or impossible to disguise or for a decoy to duplicate. Second, wake-homing is a specialized anti-surface ship technique; so it would be possible, in theory, for a wolf pack of submarines to fire wake-followers toward a targeted formation without fear of hitting one another. That safety would not be possible with conventional passive-homing torpedoes.

All homing techniques for torpedoes are effective only at relatively short ranges because limited torpedo dimensions cause frequencies to be high. However, shipboard or submarine sensors, which can operate at much lower frequencies, can reach out much farther. One way to combine the 2 capabilities is to provide the torpedo with mid-course guidance in the form of a wire. Wire guidance can also be used to correct the course of a nonhoming torpedo attacking a maneuvering target, a technique used by the heavy Swedish torpedoes. This type of remote control was used as early as World War I by the Germans and was tried both in Germany and in Italy during World War II. In its simplest form, wire guidance is 1-way, commands being issued by the submarine. However, in some recent applications, the wire is used both ways, the operator on board the submarine receiving the picture generated by the torpedo-borne sonar. The passive triangulation that results can be used to negate some countermeasures a target may take.

Torpedo homing naturally inspires the development of torpedo countermeasures. For a surface ship faced with passive homers, the natural countermeasure is a noise-maker whose output more or less duplicates that of a ship. There are 2 main technical problems. First, although the level of noise must be high enough to fool the approaching torpedo, the noise cannot be allowed to blank out sonar operation: generally, the signal output of the decoy must be controlled. Second, there is always some fear that, having attracted (but not destroyed) a torpedo, the noisemaker will merely lead the torpedo closer to the targeted ship. Most modern missiles (including torpedoes) have some form of re-attack logic, which causes them to try again

after having been fooled once. The decoy must be far enough from the targeted ship that the torpedo, trying again, hears the decoy rather than the ship.

Countering a wake-follower seems altogether a bleaker prospect because no noise-maker on earth can make anything that resembles a wake.

The point is that, to be effective, existing types of countermeasures must be closely matched to the weapons they counter. Against a torpedo, the alternative is a direct-kill countermeasure, an antitorpedo weapon. There have been several such programs since World War II, both in Britain and in the United States, but they have generally died because the problem of finding and killing a small torpedo is so very difficult technically, and is also very expensive.

From a submarine's point of view, acoustic countermeasures come in 3 varieties. First there are self-propelled submarine simulators, which may mislead the sonar operator and which may also attract passive-homing torpedoes. Then there are sonar transponders, either hull-mounted or ejected, which can confuse an active pinger. Finally, a submarine may eject bubble-makers, which will create a screen between the boat and an active pinger. Since the bubbles reflect pings, the torpedo will be unable to see into the screen and may home on the screen itself. What happens afterward depends on the torpedo's re-attack logic. The bubble screen may also be intended to obscure the submarine and its track from a longer-range sonar. In that case, a torpedo with a 2-way wire may be steered around the bubble, to look beyond.

For example, in a submarine vs. submarine engagement, the targeted submarine will want, first, to break track. It must accelerate, and it will, consequently, make more noise. To cover that acceleration, the submarine can launch decoys and create a bubble screen. The targeted boat can also fire back (without wire guidance) at the pursuing submarine in hopes of escaping while the latter evades. If track-breaking fails, the targeted submarine can still hope to counter torpedoes fired by the pursuing submarine, either by firing back (to force the pursuer to break the guidance wires while counter-evading), by using decoys, or, more likely, by using both methods. It is also possible to imagine using hull-mounted transmitters, in appropriate sequence, to break lock, just as a surface ship would use a radar lock-breaker and chaff launchers.

Mines, including ASW mines, are listed separately.

Minehunting sonars, which may be used to detect bottomed submarines, are listed in the Mine Warfare section.

Surface-search radars, which are often used by ships and aircraft to detect periscopes and snorkels, are listed in the Strike/Surface Warfare section.

SONARS AND UNDERWATER FIRE-CONTROL SYSTEMS

AUSTRALIA

◆ ASSTASS

ASSTASS is the Australian Surface-Ship Towed-Array Surveillance System. The Royal Australian Navy decided against using frigates for long-range submarine surveillance, and in favor of buying a specialized surveillance towed array to be deployed on board inexpensive specialized ships, similar in theory to the U.S. SURTASS. A formal Naval Staff Target for such a system was formulated. Unlike SURTASS, ASSTASS would reportedly process its data on board. It is not clear whether the Kariwara thin-line wet end would be suitable for ASSTASS. As of 1989, ASSTASS was expected to enter service in 1996. An RFP for a project-definition study was released in August 1989, at which time the Australian government hoped that the effort would be completely indigenous. The towing vessels are to be suitably modified commercial offshore-support craft with on-board signal-analysis and -display equipment.

◆ Kariwara

The Australian-developed thin-line towed array is for use by surface ships or submarines. The requirement was stated in 1984–85, and the array was developed by the Australian Defence Research Center; trials began in 1987–88. The array is reportedly 30 or 40 mm in diameter, consisting of hydrophones in long embedded in a fully reelable ropelike matrix. The array is unique in being manufactured in continuous lengths, using rope-making techniques. The core, a buoyant polypropylene rope in which the electronics are embedded, is surrounded by a gel-filled weave of electrical conductors and Kevlar fibers, the whole being covered with a polyurethane sleeve.

Kariwara grew out of a 5-year Australian-U.S. project, Boolee, of the 1970s. Boolee reportedly demonstrated the value of towed arrays in Australian waters; but the RAN found the existing 90-mm-diameter fluid-filled type unsuited to its diesel-electric submarines and asked the Defence Science and Technology Organization (DSTO) to devise a light reelable array that could be stowed in a submarine casing. Reelability was presumably important because an Australian submarine would have to operate in shallow water. Sections of Kariwara's wet end were tested on board the submarine *Oxley* in 1982. *Otama* began Kariwara trials in 1984, and *Otama* received the first clip-on operational version in April 1987.

Presumably, these were predevelopment arrays since the Kariwara development and production contracts are currently being competed. Plessey completed project-definition studies in 1988. The Invitation to Register Interest (ItR) for full-scale engineering development closed on 25 July 1989. Two preproduction arrays are to be manufactured, based on new technology, not that developed by Plessey. Kariwara is still envisaged as a low-cost array and as a candidate for installation on board the new Australian submarine. Plessey got a contract for 2 slim-line arrays for 2 submarines for delivery in November 1991, with a performance less than that envisaged for the final Kariwara. The likely bidders are Plessey, Ferranti, Marconi, BAe Australia, and AWA.

◆ Mulloka

This Australian-developed replacement for British hull sonars such as 177 and 184 was developed in the early 1970s. The prototype was completed in 1975 and tested on board HMAS *Yarra* through 1979. The initial production contract was let in 1980, for 5 sets for the "River"-class frigates (installed 1983/84). In contrast to other Western sonars, Mulloka operates at a relatively high frequency (transmission, 6–11 kHz; passive, 3.5–14 kHz), to produce a very narrow but powerful beam. The cylindrical transducer consists of 96 staves, each of 25 spot transducers, to produce very narrow beams. It forms beams digitally and uses random transmission to reduce warning to submarines, transmitting for 1–4 sec and then listening. The object of the design is to achieve very solid coverage out to about 10 kyd, accepting virtually 0 coverage at greater ranges. Mulloka resulted from a late 1960s requirement, and an R&D contract was let to EMI of Australia in the early 1970s. Honeywell produced the transducer.

Mulloka will be installed on board the 2 U.S.-designed *Oliver Hazard Perry*-class frigates that are building in Australia, in preference to the U.S. SQS-56.

◆ PIPRS

Ping Intercept Passive Ranging is a concept developed by the Australian DSTO (Defence Science and Technology Organization) Sonar and Surveillance Group. It uses existing arrays in Australian *Oberons* and is currently in production at Sonartech (Sydney).

CANADA

◆ BQG-501

See Micro-PUFFS under U.S. sonars below.

◆ SQR-501

The Canadian towed array (CANTASS) uses a U.S. SQR-19 "wet end" and a Canadian (Computing Devices) signal processor. The requirement was stated in 1981, and in mid-FY84 the U.S. Navy offered 6 SQR-19s. The Canadians opted to develop their own dry end. CANTASS was developed in 1983–87. A system was tested on board HMCS *Fraser* in 1986–88 under the designation ETASS. CANTASS is to go on board all 12 "City"-class frigates

A towed array, probably SQR-18, on board a Canadian destroyer at Halifax, 1989. The fish is the towed body used in the U.S. SQS-35/SQR-18 combination. (G. Till)

SQR-19 or SQR-501 port in the transom of HMCS *Annapolis*, 1989. (G. Till)

and also on board 2 modernized *Annapolis*-class frigates in 1990-95.

Canadian experiments using quarter-scale arrays began in 1980. The one-half scale ETASS was tested on board HMCS *Nipigon* in 1983 and on board HMCS *Iroquois* in 1984; in 1985 it was decided that ETASS would be fitted semipermanently on board HMCS *Fraser*, replacing her ASW mortar and several internal compartments. In this version the length of the tail was doubled, bringing ETASS up to full SQR-19 size. However, the handling system is much more primitive than that of the full CANTASS. The *Fraser* installation introduced a new third console, for a supervisor who analyzes the collated information, leaving the 2 primary operators free to watch incoming data and to do primary search. This configuration proved successful enough to cause a change in the CANTASS design to incorporate the third position. Installation began in October 1986 and was complete by early December.

The first full CANTASS will be an SQR-19 tail combined with a commercial Motorola 68020/UYS-501 Teamed Architecture Signal Processor (TASP). Later examples will use a fully militarized 68020/UYS-501 by Computing Devices of Canada.

◆ SQS-501

See Type 162 under U.K. sonars below.

◆ SQS-502

The Canadian derivative of the British Type 170B is for Limbo fire control. See U.K. sonars below.

◆ SQS-503

This hull-mounted medium-frequency (8-12 kHz) scanning sonar is found in Canadian frigates of the *Restigouche* and earlier classes and in the underway replenishment ships. SQS-503 equips the French *Foch*-class aircraft carriers. This sonar was developed by Canadian EDO of Cornwall, Ontario, from an abortive U.S. set.

◆ SQS-504

SQS-504 is a medium-frequency (8-15 kHz) variable-depth searchlight sonar. The British Type 199 is a derivative. See the U.K. entry below for details.

Canadian work on VDS dates from 1947, and a naval staff project, code-named Dunker, began in April 1949. The dipping sonar was particularly wanted to exploit a sound channel lying between the warm surface layer and the warm bottom layer on Scotian Shelf off the Canadian east coast. The first trials employed a dipping version of the British Type 144, on board the fleet minesweeper *New Liskeard*. It turned out that, with both the target and the sonar in the axis of the channel, ranges as great as 9400 yd could be achieved. Even when both were at the upper edge of the channel, the range was 4200 yd, far beyond the performance of a hull-mounted Type 144. The early trials employed a transducer dipped from a stopped ship, and through the early 1950s work proceeded on viable towed bodies. They, too, carried Type 144 transducers.

Through 1953 the project concentrated on submarine detection in the shallow Gulf of St. Lawrence and off Halifax, where conventional hull sonars were often useless. In 1953, however, the project was redirected toward achieving maximum possible sonar range (for early warning) by placing the transducer at the optimum position under a much wider variety of conditions. By this time much work had been done on suitable towing bodies. The first fully developed experimental system, CAST/1/X electronics in a body designated TRILBY Mk V, was turned over to the Royal Canadian Navy on board HMCS *Crusader*, a destroyer.

CAST/1/X was re-engineered as SQS-504. In tests in 1958, off Bermuda, off New London, on the Scotian Shelf, and in the Gulf of St. Lawrence, it outperformed the hull-mounted Type 144 by a factor of 5. This result led immediately to a decision to include SQS-504 (and the associated SQA-501 hoist) in the mid-life modernizations of the *St. Laurent*-class frigates. In addition,

CAST/1/X outperformed the contemporary British Type 192X experimental VDS (which was then mounted on board HMS *Brocklesby*). Hence the British decision to adopt SQS-504 as Type 199.

Further development was concerned largely with handling gear, which caused particular problems in heavy weather. By 1964 there were complaints from sea that the system was useless, and a get-well program had to be instituted. The lessons learned at this time were applied to the VDS version of SQS-505 (which uses a hoist designated SQA-502). SQA-502 permits operation at higher speeds and at greater depths, and it is officially claimed that overall search capability is 20 times that of SQS-504. In early trials, it achieved a range of 27,500 yd compared to 5000-7000 yd for SQS-504.

◆ SQS-505/509/510

SQS-505 is the hull sonar in the *Iroquois* and *Halifax* ("City") classes. The *Iroquois* class has the same transducer in a variable-depth fish (SQA-502 hoist). In the first 6 "City"-class frigates, SQS-505 will be integrated instead with the SQR-501 towed array. The sonar was designed to be fitted in either a fixed or a retractable dome (in the former case, the transducer can be either fixed or retractable).

SQS-505 uses a 36-stave (10 elements/stave) cylindrical transducer (4 ft diameter × 4 ft) producing a 10 × 10-deg beam. The hull dome is 14 ft long, and the towed body is 18 ft long and weighs 14,000 lb (10,000 lb submerged). Operating frequencies are 6.4, 7.2, and 8.0 kHz (bandwidth 400 Hz). There are 36 beams, with 16 channels/beam (25 Hz wide). Nominal range is 200-32,000 yd (range scales 2, 4, 8, 16, 32 kyd). Target doppler: ±40 kt. Modes: ODT, triple RDT (TRDT), directional transmission (DT), acoustic short-pulse echo classification (ASPECT), and swept FM pulse wide-band mode. Pulse lengths: 2.5, 10, 40, 480 msec. Source level: 126 dB (ODT), 135 dB (TRDT, DT). Passive operation: 10 kHz. Signal processing: matched filter with time, function automatic gain control (TFAGC) and frequency, function AGC (FFAGC) or incoherent (wide-band) processing. There are 2 CRTs, 1 showing range and doppler (range-doppler indicator, RDI), the other passive, plus alphanumeric readouts. In the RDI mode, the sonar uses a DVST tube (A-scan display of 7 successive range-only traces with doppler). SQS-505 can track 5 targets while searching for more.

The sonar can operate in both manual and computer modes, providing both digital and analog data. Targets are classified by doppler, by a separate steerable audio channel, or by ASPECT. This sonar can track multiple targets, and it can display a 12-ping history, a 5-ping history, or raw video.

SQS-505 has been criticized for lacking true LF capability, and for a time it appeared that the "City" class would be equipped instead with SQS-509; but they have SQS-505(V)6, with its LF

SQS-505 VDS on board HMCS *Gatineau*, August 1988. (S. Terzibaschitsch)

passive capability. SQS-505 TASP with digital acoustic processing and SHINPADS display was tested on board an *Iroquois*-class destroyer in 1984.

Versions:

- (V)1 Hull mounted version.
- (V)2 VDS version.
- (V)3 AOR hull-mounted version.
- (V)4 Number of ASPECT pulses limited to 20. Hull version.
- (V)5 Number of ASPECT pulses limited to 20. VDS version.
- (V)6 New version with new transmitter and receiver (OA-5168 transmitter and OA-5119 receiver in place of OA-5118 and OA-5116). Source level: 133 dB; pulse length 10 and 40 msec. Doppler: ± 40 kt at 7.2 kHz (operates at 6.4, 7.2, or 8.0 kHz active, but at 4.5 kHz passive). This version is designed specifically to work with the SHINPADS combat direction/data system. Although similar in form to the (V)4 version, it has no separate control indicator group since the SHINPADS consoles substitute. Passive modifications: operation at 4.5 kHz and a steered passive mode.

Users: Belgium (*Wielingen* class: SQS-505A), Canada (Tribal class, including VDS version; destroyers modernized under DELEX program; *Protecteur*-class underway replenishment ships), Greece (ex-Dutch "Standard" frigates), India (first 4 *Nilgiri* class, hull and VDS), and the Netherlands ("Standard" frigates). The last 4 Dutch "Standard" frigates use a lower-frequency (5-kHz) version, SQS-509, which is closely related to the Dutch PHS-36. The Canadian "City"-class frigates have SQS-505(V)6, which includes a computer-aided detection and tracking feature developed by Westinghouse Canada. This version feeds data directly into the ship's SHINPADS combat system bus. SQS-505 was originally chosen for the U.S. *Perry* class (in preference to the more expensive SQQ-23). The generally comparable SQS-56 was chosen very late in the design process to permit redesign of the frigates to take a second helicopter without increasing their total cost (1974). SQS-505 was developed in 1966-69 for the Tribal class.

SQS-508 was an abortive follow-on, using the same transducer (10-, 40-, or 80-msec pulses), but -508 was much more powerful (224 dB ODT, 233 dB TRDT or DT). It used a digital receiver. In CW mode its signal processor was a 16-replica correlator, and in FM mode it was a replica correlator. It could be mounted (as a VDS) on board ships of 400 tons and greater displacement.

SQS-509 operates at 4.8, 5.4, and 6.0 kHz, and power output is increased by about 2 dB; transducer size is increased by a ratio of 4:3. SQS-509 operates passively at 3.125 kHz. Nominal range matches that of SQS-505. Source level: 137 dB. Pulses: 10 and 40 msec. Doppler limits: ± 40 kt.

SQS-510 is essentially an SQS-505 combined with an SQR-501 towed array. Because the array processing is so important, the prime contractor is Computing Devices Co. rather than Westinghouse of Canada, which was responsible for the SQS-505 series. Like SQS-505(V)6, SQS-510 is designed to use SHINPADS or other standard multifunction displays rather than special sonar displays or indicators. The associated computer is UYK-502, and the signal processor is UYS-501. This sonar was adopted for the Portuguese MEKO frigates (the analogous Greek and Turkish units have SQS-56). As of the fall of 1990, it seemed likely that Portugal would buy SQS-510(V) for her 4 existing *Joao Belo*-class frigates.

◆ SQS-507/HS-1000 Series

"Helen," a lightweight towed sonar, was developed specifically for the ASW hydrofoil *Bras d'Or*. Development began in 1963, and the sonar was delivered in 1968. This work, in turn, led to the HS-1000 series. SQS-507 was a smaller, simplified version of SQS-505.

The HS-1000 series is a joint Canadian navy/Westinghouse of Canada development project for fast attack craft, based on experience with the SQS-507 towed sonar. HS-1001 is a light-

weight VDS; -1002 is a lightweight hull sonar; -1003 is a VDS for small ASW ships; -1007 is a medium hull or VDS; and HS-1001/2, -1002/3, and -1007/7 are combination installations, the hull and variable-depth sonars sharing a common transmitter and signal processor. The VDSs use a 330-ft cable and can be towed at 35 kt. HS-1007 uses the same receiver, display, transducer, and variable-depth fish but an SQS-505 power supply, for 4 times the power of HS-1001 and -1002 in ODT mode, and 20 times the power in tribeam mode. HS-1001/2 operates only in ODT mode.

R&D began early in 1970, and a prototype was completed in 1972. The HS-1001 version was tested on board the U.S. hydrofoil *High Point* in 1980. Details of sales have not been reported, but in 1972 sonars of this type were reported in production for the West German navy. That report may reflect projected installation in the abortive German hydrofoil (equivalent to the U.S. *Pegasus* class).

In 1985, 2 Westinghouse hull and 3 VDS sonars were reported sold to the Indian navy, and the HS-series would seem to have been the most likely candidate. The VDS arrays were carried in fish built by Fathom Oceanology, Ltd., of Canada. Both hull and VDS use the same array, which has 21 staves.

There is a new receiver (with new software) developed by CDC, and the sonar is designed to feed data directly into a SHINPADS or STACOS (Signaal) data bus.

◆ Towed Arrays

The Canadian Department of National Defence is supporting two new towed-array projects:

Focal Technology uses fiber-optic telemetry in a standard-diameter wet end (with 6 multipurpose fibers). The Focal wet end was tested at sea in June 1987.

Hermes Electronics has produced replacement multimodule arrays similar in performance to SQR-19 but 64 mm (a reduction of about one-third) in diameter.

◆ CTS-36 RDN

C-Tech has received a contract for this multibeam, scanning, hull sonar to equip the Danish IS-86-class fishery-protection frigates and expects to receive additional contracts for the hull sonars of the StanFlex 300-class (*Flyvefisken*-class) corvettes. CTS-36 is a more sophisticated version of the C-Tech family of light commercial (fish-finding) hull sonars already in widespread use (developed since about 1970). It operates in both CW and FM (chirp 1 kHz wide) at 36 kHz (33 kHz optional), both active (ODT and SDT) and passive modes. Active modes: omni (ODT or directional CW transmission, automatic target detection; audio beam continuously steerable through 360 deg; transmit sector width and position selectable); tracking (3 separate receiving beams, each 6×6 deg, are manually locked onto each of 3 separate targets; transmission is FM chirp or CW); surveillance (12-deg search beam stepped through operator-selected sector; selected transmit sector width); and search MCC (maintenance of close contact: a broad 30-deg receive beam is depressed to maintain contact with a close-in target). There is a separate audio receiving beam (800 Hz). The sonar beam is continuously adjustable electronically between $+8/-24$ deg, stabilized for roll and pitch. Receiving beam is 6×6 deg. Transmission: ODT or SDT. The transmitter uses 270 50-W channels. Source level is 220 dB (re 1 microPascal at 1 m). CTS-36 uses either the ship's own display or its own 1280×1024 -pixel display (7 colors). Display modes: PPI, B-scope, and bearing-time for tracking, all oriented true north or to the ship's bearing.

The first CTS-36 sonar was delivered to Denmark in February 1991. A somewhat simpler variant was installed in August 1990 on board the 3 Canadian ships sent to the Persian Gulf to help them evade mines.

◆ New Dipping Sonar

The Canadian navy is buying a variant of the EH-101 helicopter as its NSA (new shipboard aircraft). The NSA systems integrator, EHI Canada, issued RFPs for a dipping sonar in April 1988.

By September, 5 teams had submitted proposals: Lockheed Canada-Sanders, Thomson Sintra-GEC Avionics (AQS-934 processor), Bendix (HELRAS), Thomson Sintra (FLASH), Martin Marietta (HIPAS), and Plessey-CDC (AQS-503 system, consisting of Cormorant and UYS-503). As of mid-1989, the Canadian Department of National Defence (DND) was expected to select 2 bidders for a final selection in mid-1990, but the choice has been delayed.

DND already has a HAPS (Helicopter Acoustic Processing System)-development project, using an AQS-503 (UYS-503 plus Cormorant sonar) supplied by CDC (which leads the NSA Mission Systems Consortium) and Plessey. AQS-503 was evaluated on board a barge in Bedford Basin, Halifax, in 1988 and was formally delivered in April 1989 for flight trials on a Sea King. The UYS-503 processor may later be used with Bendix and Martin Marietta wet ends as part of the NSA dipping-sonar selection.

◆ ASROC Fire-Control System

Canadian *Restigouche*-class frigates rebuilt in 1968-73 have a Canadian-developed ASROC FCS, the first Canadian all-digital shipboard system (which was developed by CDC). Reportedly, it was developed because of bad experiences with the U.S.-developed Gunar anti-aircraft FCS; the Canadian navy saw the U.S. Mk 114 as an underwater application of Gunar concepts.

◆ ASWDS

ASW Data System is used on board the "Tribal"-class and west-coast *Restigouche*-class frigates. It employs a Signaal SMR computer to track up to 27 targets detected by an SQS-505 sonar, and (in the "Tribal" class) provides these data directly to the ship's CCS-280 combat system. In an Improved *Restigouche*, a second display is provided in the Operations Room, and data are transmitted in analog form to the plotting table, driving 2 contact lights, the plotters either using grease pencils or sitting at the ASW system console. In the latter case, 1 contact light is used for the contact, the other for the helicopter the ship is conning into position to reacquire and attack the contact. Signaal developed most of the system. Typically, ASWDS employs 2 primary and 1 remote sonar indicators with vertical CRTs, plus a sonar signal injector and a computer and sensor weapon converter assembly. The system also includes ASROC- and mortar-firing panels and radar-data panels. It uses digital displays for sonar (spiral-sweep) video and alphanumeric. The displays can be true-motion and off-center. The maximum sweep display range is 32 kyd, and the maximum symbology display range is 64 kyd; range scales are 2, 4, 8, 16, 32, and 64 kyd.

The system was originally to have used half of the L-304 computer power of the CCS-280 system. However, the Signaal computer was purchased as an offset to a Dutch purchase of Canadian-built F-5 fighters, so the L-304 was only half utilized.

The Canadian navy first became interested in a decentralized combat system (see CCS-280) during the development of the abortive ADACS system. The ASWDS requirement was started in 1967-68. ASWDS is UCS-280, the underwater-warfare portion of CCS-280. The prototype ASWDS was tested on board HMCS *Terra Nova*.

◆ SBF 256

This beam-former, made by Interactive Circuits & Systems Ltd. (ICS), was announced in 1987 as the world's most powerful. Whether or not that is true, it is presumably typical of current practice. Beams can be formed either by applying phase shifts to the outputs of individual hydrophones or by taking their outputs at differing (delayed) times, in either case adding them up. ICS argues that the time-delay technique it chose is superior because it is effective over a broader bandwidth. The time-delay technique requires that the output of each hydrophone be available at any arbitrary time. That would entail an impractically high sampling rate. Instead, SBF 256 interpolates between received hydrophone inputs to estimate the required values; that in turn reduces the sampling rate to the acceptable figure set

by the highest frequency to which the system need respond. Interpolation resolution is 1024:1 (interpolation is equivalent to a thousandfold increase in sampling rate).

ICS argues that the time-domain techniques it chose are superior to the alternative, to form beams in the frequency domain (i.e., to do an FFT before beam-forming) because they are simpler and because they produce an audio output in each beam. An SBF 256 accepts inputs from each hydrophone in sequence; each cycle of samples (from hydrophone N back to hydrophone N-1) is a frame, up to 512 words long. The output frame, a sequence of beam samples, is up to 256 words long. Since total throughput is fixed, there is a trade-off between the sampling rate applied to each hydrophone or beam and the total number of hydrophones or beams (see below). Each frame is, in effect, a sample at 1 point in time; each input or output channel is represented by a series of such samples, frequent enough to represent a continuous signal. For example, if each of 512 hydrophones is sampled at 1 kHz, the beam-former receives 512,000 data points each second. That is equivalent, in terms of arithmetic workload, to 128 hydrophones operating at a sampling rate of 4 kHz. An output of 256 beams at this sampling rate equals 256,000 output data points/sec. These figures explain the need for a very high throughput, in this case 2 GOPS, using 16-bit (4-bit exponent) floating-point data.

The beam-former weights (shades) some of the hydrophone outputs to reduce the sidelobes of the beams. It can handle up to 512 hydrophones, the delays and shadings compensating for an arbitrary configuration (e.g., linear, circular, nested, 3D) described by the system software. Generally, the required time delays will not correspond exactly to intervals between samples. To avoid an impractically high sampling rate, SBF 256 estimates (interpolates) the required values; the beam-former can then use the lower sampling rate consistent with the highest usable hydrophone frequency. Interpolation is equivalent to dividing the time interval between samples by 1024. The speed of the interpolator, 12.5 million taps/sec, determines overall throughput, using 8 taps/channel, i.e., using a total of 8 samples to estimate the signal through a channel so as to interpolate properly. For example, given 512 inputs (hydrophones), the interpolator can handle a sampling rate of 3.1 kHz. The interpolator can also work (more accurately) at 16 taps/channel.

SBF 256 uses time-domain beam-forming. Frequency-domain is the alternative (the FFT is carried out before the beams are formed). ICS argues that its choice is preferable because it provides a direct audio output in any given beam, because its hardware is simpler, because each beam can easily be separately shaded, and because very high bearing resolution can easily be achieved.

SBF 256 consists of a VME bus carrying 2 major elements: an I/O board and a series of 16 beam-former cards (plus 1 diagnostic card). Each beam-former card performs more than 125 MOPS, simultaneously forming 4 beams by shading, interpolation, and delay-summing and 16 by multiplexing (i.e., by accepting a lower data rate). The number of output beams depends on the number of inputs. With identical shading for each beam, 256 beams can be formed with up to 128 hydrophones, 128 beams for 129-256 hydrophones, and 64 beams for over 256 hydrophones. If each beam is to be shaded uniquely, the beam-former produces 256 beams for up to 64 hydrophones, 128 for 65-128, and 64 for 129-256; it cannot accommodate more than 256 hydrophones. Given constant computing power, the maximum available channel-sampling rate (which determines the maximum frequency at which the system can operate) depends on the number of hydrophones and beams:

Hydrophones	BEAMS		
	Up to 64	Up to 128	Up to 256
32	48 kHz	24 kHz	12 kHz
64	24 kHz	12 kHz	6 kHz
128	12 kHz	6 kHz	3 kHz
256	6 kHz	3 kHz	—
512	3 kHz	—	—

The VME bus also carries an on-board CPU, which enters parameters into the I/O board and the beam-formers; it holds the system software in PROM. SBF 256 also communicates with a host computer, which sends it commands and data and which receives the beam data via a 16-bit parallel link.

DENMARK

◆ Submarine Tactical Data System

Terma's tactical data system is adapted to submarines for the Danish *Kobben* and *Narhvalen* classes. It supports the Terma torpedo FCS, which has its own processor cabinet and which can control 4 wire-guided torpedoes simultaneously. The main components are the data processing unit (DCU), the graphic display (GD), the system terminal, and the torpedo-guidance unit (TGU). The graphic display is a 20-in-high color raster monitor, whose lower portion is used for alphanumeric data. The upper portion can show 3 alternative pictures: a general operational plot (GOP), which is a PPI-like picture including tracks, ESM data, and maps, and which can be ship- or geographically oriented; a contact evaluation plot (CEP), a waterfall display oriented to passive sensors; and an attack plot (AP), which extracts data from the GOP and the CEP to produce a picture of the local attack situation, including vector diagrams, predictions, and recommendations for torpedo attacks against selected targets. The system terminal is the means of communication with the system; it consists of an alphanumeric keyboard, 60 dedicated function keys, and a roller-ball.

FRANCE

SONARS

With the merger of Sintra-Alcatel into Thomson-CSF in 1987, Thomson Sintra is now the sole supplier of French naval sonars.

◆ SLASM

SLASM (*Système de Lutte Anti-Sous-Marin*) is the future (1990s) French ASW system, consisting of a very low frequency (well below 2 kHz) transmitter in a towed "fish," with a dual towed array receiving the resulting signals. The fish will also carry a medium-frequency transmitter (as in DUBV 43), and there will be a medium-frequency hull sonar. A dual towed array, as in the earlier frigates, will function both as a submarine detector and as a torpedo detector.

A French description of this system emphasizes the "deep integration" among elements since the arrays, processors, and displays will have to shift functions, the displays allowing the operators to choose an optimum configuration (depending upon both physical oceanographic circumstances and the tactical situation).

Other automatic inputs will be sonar intercepts and helicopter-laid sonobuoys, both active and passive.

The modernized *Tourville* class will be the first to be fitted with SLASM. The first tests of the very low frequency active sonar were conducted on board the trials ship *Commandant Rivière* early in November 1987.

◆ DSBV 1

DSBV 1 is a torpedo-detection sonar (passive) found in postwar French destroyers and escorts, at least up through the *Commandant Rivière* class (where this sonar shares a dome with DUBA 3). DSBV 1 operates over the 5–40-kHz range and presumably shares some of the components of Velox (DUUG-1).

◆ DSBV 61 (DSRX 61X) (FLUTE)

DSBV 61 is the French towed array for surface ships. DSRX was the experimental version tested on board *L'Agenais*. Reportedly, the array consists of 50 hydrophones at the end of a 1000-m cable. The requirement was stated in the mid-1970s, and Thomson Sintra received a research contract in 1977, delivering the prototype in mid-1980. Trials were completed late in 1984, and DSBV 61 was approved for production early in 1985.

It was announced in January 1988 that the Netherlands would

buy this array (rather than SQR-18) for M-class frigates. For the Dutch, the processor is derived from the Mangouste airborne processor and interfaces with a SEWACO-VII combat system.

◆ DSUV 2

This passive low-frequency (i.e., sonic) keel (bow) array of *Narval* (now extinct) and *Daphne* classes replaced the earlier G36. G36, in turn, was a 36-transducer array descended from France's standard prewar passive arrays, G12 and G16 (12 and 16 transducers, respectively). DSUV 2 is not a GHG-style array (like the U.S. BQR-2) but is much smaller, and the transducers are apparently spot hydrophones. DSUV 2 is associated with a correlator (GC 02) that automatically scans in bearing, registers all noise sources on a hard-copy printer, finds their direction, and tracks them automatically. This sonar system incorporates both a CRT display and an audio output.

DSUV 2B was first tested in 1977, and the first unit was installed in 1979 on board the submarine *Rubis*. DSUV 2B is now the primary sonar for French nuclear attack submarines, in combination with DUUX 5 (FENELON).

◆ DSUV 22 (Eledone)/Scylla/Type 2040

DSUV 22 is the passive hull array of the *Rubis* and *Agosta* classes.

Eledone is the commercial version of DSUV 22, adding other arrays to form an integrated modular sonar system for submarines. Eledone consists of some or all of: a passive bow array, an intercept array, flank arrays, a towed array, passive-ranging arrays, an active array, and a mine-avoidance sonar. The primary (search/attack) active sonar operates at 5 kHz (source level 215 dB for search) and incorporates an 8–11-kHz underwater telephone. Transmission is CW or FM, and the passive bow sonar is used for reception. The active transducer is a planar-array searchlight, active operation being used primarily for single-ping ranging at 5 kHz.

The bow transducer is 1.25 or 3.5 m (49.3 or 137.8 in) in diameter and 0.8 or 3 m high (32 or 64 staves; a larger 96-stave version was also developed, but it was not sold), operating at up to 12 kHz in 2 or 3 frequency bands (e.g., 1–5 and 5–12 kHz for the smaller version). There are 128 preformed beams, for 360-deg coverage. Eledone can automatically track 4–12 targets, providing very accurate azimuth data. It can also provide audio output or spectral analysis in 1 or 2 directions. An optional associated intercept receiver operates at 2–80 kHz, i.e., from LF search to torpedo seekers. The transducer is typically mounted on the submarine's sail. Target emissions are analyzed using

Eledone passive attack (bow) array. (Thomson Sintra)

Eledone active array, typically located in the submarine sail. (Thomson Sintra)

tunable low/high-pass filters. The associated PPI shows active transmissions in 3 bands (2–7.35 kHz, 7.35–27 kHz, 27–80 kHz) with an accuracy of 3–5 deg.

The associated single-ping active sonar operates at 5 kHz (4-kW peak power) with an unambiguous range of 100–1400 m. This sonar can also be used as a passive receiver (1–6 kHz) if the main hull array fails.

Eledone uses the same MIRTA 1500 series computers as do Beluga and Remora.

Scylla, the sonar system of the Australian Type 471 submarine, is an advanced version of Eledone, with the following arrays: cylindrical bow, flank, distributed passive-ranging, intercept, active (in the sail), mine-avoidance, and self-noise-monitoring (astern of the flank arrays, on each side). The towed array is the Australian Kariwara.

For Type 2040, see U.K. sonars below.

◆ DSUV 23

DSUV 23 is a passive low-frequency hull array found on strategic submarines.

◆ DSUV 61

A towed array for strategic submarines, used primarily for evasion, DSUV 61 is comparable to BQR-15 and Type 2023. Tests were conducted in 1974–77, the first installations following in 1977–78. *Le Tonnant* and *L'Inflexible* were completed with this array, and the 4 earlier units were retrofitted.

◆ DSUV 62

DSUV 62 is a towed array for attack submarines, used for passive fire control rather than evasion. Thomson-CSF received a research contract in 1975–76 after work was already proceeding on DSUV 61. The prototype was completed in 1979, tests following late in 1980, and approval for production in 1981. The first unit was installed on board the submarine *Rubis* early in 1983.

Typical modern French submarine sonar-intercept array. (Thomson Sintra)

◆ DSUX 20

DSUX 20 is a new active/passive multifunction sonar for the *Améthyste* class. As of 1989, it was being tested on board the trials submarine *Dauphin*.

◆ DSUX 21

A multipurpose system for *L'Inflexible* and earlier strategic submarines, DSUX 21 consists of bow or flank passive arrays. It replaces DSUV 23 in all strategic submarines.

An entirely new system for the new strategic submarines (*Le Triomphant* class) is being designed. It will be integrated with their command/control system, SET (*Système d'Exploitation Tactique*).

◆ DUAA-2A

DUAA-2A is on board French-built *Daphne*-class submarines as well as many German-built Type 209s (including those of Colombia, Ecuador, Greece, Peru, and Venezuela). DUAA-2B is on board French *Agosta*- and *Rubis*-class submarines.

◆ DUAV 4 (HS 71)

DUAV 4 is Sintra-Alcatel's dipping sonar for the Lynx (WG-13) helicopter. Development began in 1968/69, and the sonar entered service in 1975. DUAV 4 is also used by the Dutch and Swedish navies. It operates at 21, 22.5, and 24 kHz (source level 119 dB), and the maximum depth is 495 ft. There are 3 operating modes: search (bearing and range), plot (bearing, range, and speed), and passive.

DUAV 4 is 1 of an HS-70 series of dipping sonars; HS 73 was announced in 1975 (for use on board French navy Lynx helicopters). HS 73 uses a coherent processor to reject reverberation echoes in shallow water.

Studies for DUAV 4 began in the late 1960s, with R&D work in 1968–69 and tests in 1972–74; the sonar entered service in 1975, with the first foreign sales were in 1978. Reported users, as of the end of 1987, were France (58), the Netherlands (12), and Sweden (10). DUAV 4 was small enough to fit a Lynx helicopter. Most Lynx operators do not use dipping sonars at all; these aircraft deliver torpedoes to targets detected by hull sonars, in some cases using MAD for final target location. The

The Thomson Sintra family of helicopter dipping sonars. Left to right they are DUAV 4, HS 12, and HS 312. (Thomson Sintra)

Royal Navy considered adding a dipper as part of its Lynx upgrade program but ultimately could not afford it. DUAV 4 is light enough so that a Lynx can also carry light antiship missiles, such as Sea Skua or AS 15TT. The French navy used this sonar on board its large shore-based Super Frelon helicopters. In their case the advantage of the light weight was that the helicopter could also carry Exocet antiship missiles (AM 39s) and a long-range surface-search radar for targeting. Reportedly, DUAV 4 has not been particularly successful, and it has been replaced in French service (initially on the Super Frelons, but now also on Lynxes) by HS 12 (see below). Production ended about 1987. The other 2 buyers, the Netherlands (Lynx Mk 27/81) and Sweden (KV-107) still use this sonar. Reportedly, the Dutch navy plans to replace its DUAV 4s with HS 12s, but funds are not yet available. The German navy uses AQS-18 on board its Lynxes, and Portugal will use AQS-13 on hers. Argentina has 2 Lynxes equipped with Type 195. At one time Westland apparently offered this sonar as an option; it proved too heavy, and a Dutch order was changed to DUAV 4. Libya has 6 Super Frelons equipped with the modified HS 73 sonar and with L5 torpedoes (and Exocets). Both India and Indonesia ordered DUAV 4 for large helicopters but ultimately received HS 12 instead (see below).

Other naval Lynx operators (and thus potential purchasers of sonars comparable with DUAV 4 or HS 12) are the Royal Navy (HAS Mk 2, 3, and 8), Brazil (Mk 21), Denmark (Mk 80), Korea (Mk 99), and Nigeria (Mk 89).

HS 70 (DUAV 1) was an earlier dipping sonar, now obsolete. It was probably carried only by the French navy's Super Frelon helicopters (replaced by DUAV 4 and then by HS 12). South Africa bought both the Super Frelon and the Puma, and some of her helicopters may carry dipping sonars. Israel bought the Super Frelon and may have bought some French dipping sonars. For details of HS 70, see the previous edition.

◆ DUBA 1

This searchlight attack sonar for postwar French destroyers (*Surcouf* class) and frigates is designed to control K-1 straight-running torpedoes (the French equivalent of Squid). DUBA 1B operated at 23–26 kHz, with a peak power of 2.5 kW, and 8- or 20-msec pulses; range scales were 0.75, 1.5, 3, 4.5, and 6 kyd. In a *Surcouf*-class destroyer, this sonar operated in conjunction with a DUBV 1 search set.

The only surviving examples are found on board the old missile destroyers *du Chayla* and *Dupetit Thouars*, controlling Bofors-type 275-mm rocket launchers.

◆ DUBA 2

This hull attack (searchlight) sonar was found in postwar French-built 174-ft subchasers; it survives only in the Tunisian and Yugoslav navies. This craft was a modified version of the World War II U.S. 173-ft patrol craft; the U.S.-built postwar version was equipped with SQS-17A. DUBA 2 operates at 8–30 kHz, with 8-, 20-, and 200-msec pulses (the last presumably for search, since this sonar is used for both search and attack). Range scales are 0.75, 1.5, and 3 kyd, reflecting the limitations of high-frequency operation.

◆ DUBA 3

This high-frequency attack (searchlight) sonar for the *Commandant Rivière*-class frigates controls the 305-mm mortar; SQS-17 is the associated search sonar. Peak power is 4 kW (source level 126 dB), pulse lengths 10–30 (11–33 yd) or 100 msec (100 yd), and frequency 22.6–28.6 kHz (21.4 or 29.8 at reduced power). This sonar shares its dome with the SQS-17 search projector and with an underwater telephone. Sonar outputs are elevation (target depth), bearing, and radial speed (doppler analysis of a single ping).

◆ DUBA 25 (Thomson Sintra TSM 2400 Tarpon)/TSM 2080

This medium-frequency hull sonar was designed for the A-69-class Avisos and the C70AA destroyers (which cannot accommodate the big DUBV 23/43). DUBA 25 operates at 8, 9, or 10 kHz, with 30- or 90-msec pulses, and has a 10-deg beam-width (36-stave transducer, 9 elements per stave, with 36 preformed reception beams). Pulses can be CW or FM, and they can vary in length. This sonar was specially designed for use in coastal waters (on the continental shelf). Range scales are 3, 6, and 9 kyd, and the display is a PPI. The operator can place a filter over any 1 of the preformed beams to reject a narrow frequency band centered on the transmission frequency, to reduce clutter and reverberation (i.e., to limit returns to those that are doppler-shifted). For attack, special fine-bearing circuits are used, together with an auxiliary display (B-scan) showing an area 10 deg wide and covering one-eighth of the whole range scale. The transducer is 1.1 m in diameter and weighs 1500 kg.

Development began in the late 1960s, to a dual light frigate-export requirement. Thomson Sintra received the R&D

Tarpon low-frequency hull array. (Thomson Sintra)

contract in 1970, and development was complete by 1974, the first unit going to sea on board the *D'Estienne D'Orves*.

The Tarpon designation was also applied to TSM 2080. It was described as a sonar for ships displacing 2000–5000 tons. Its parameters are somewhat different from those initially published for the more austere Tarpon. In this sonar, source levels are over 220 dB in ODT mode or 227 dB in directional mode. The system produces 32 stabilized beams. All beams are subject to 2 forms of signal processing: spectral analysis (768 doppler cells formed by FFT) and pulse compression (maximum compression ratio of 300). The display console consists of 2 identical high-resolution (1000 × 1000) flicker-free color TV monitors. Total weight of the system is 6000 kg. Maximum instrumented range is 32 kyd.

Total weight of the hull-mounted sonar is less than 4.8 tons.

The associated VDS uses the same signal processor but has 24 staves and operates at medium frequency.

DUBA 26, presumably a successor to DUBA 25, has been reported.

◆ DUBM Series

See the Mine Warfare section under countermeasures.

◆ DUBV 23

France's standard hull-mounted sonar of the early 1970s is operated in conjunction with the DUBV 43 VDS. The sonar was developed in 1964–67, and the preproduction version was tested on board the *D'Estrées* destroyer in 1968. The upgraded DUBV 23 was tested in 1977.

The 23/43 combination was designed to counter quiet, deep-diving diesel submarines, i.e., relatively slow targets. The combination was chosen to achieve reliable direct-path ranges of 10–15 km, without seeking bottom-bounce or convergence-zone performance, and to support the Malafon stand-off missile and the Lynx torpedo-delivering helicopter (which reacquires the target using its own dipping sonar). Tactical-data processing was limited to a noninteractive display.

The current version is DUBV 23D. It has 6 modes: ODT, strip surveillance, sector surveillance, passive search at sonar frequency, panoramic attack, and directional (pseudo-searchlight) attack. The sonar operates at 4 frequencies between 4.9 and 5.4 kHz, producing pulses of 4, 30, 150, and 700 msec. Beams are

15 deg wide (48 vertical staves), and power output is 96 kW. Accuracy in range is 150 yd ± 1% of the range scale; accuracy in bearing is 1 deg; and accuracy in speed is less than 0.4 kt on the 0–10 kyd scale, or 1 kt on the 0–30 kyd scale.

Reported performance: 50% probability of detection against a target at 200-ft depth at 8000 yd, or against 1 at periscope depth at 14,000 yd. Reportedly, the French consider this sonar superior to the U.S. SQS-23.

In the *Georges Leygues* class, the associated VDS is modified, and it tows a DSBV 61 array, for improved performance. This improvement is described under the entry for DUBV 43.

◆ DUBV 24

DUBV 24 is a slightly less powerful version of DUBV 23. DUBV 24C, the current (1983) version, incorporates the transducer developed for the unsuccessful commercial SS24. DUBV 24 was 1 of the first French preformed-beam sonars. It uses 24 staves (8 transducers/stave); and modes are ODT, triple-beam search/receive (3 ping), stepped single-beam, searchlight transmit-receive for attack, ODT for attack (to deal with fast targets), and passive. In the ODT search mode, DUBV 24 has 6 audio beams. Tribesearch uses omnidirectional reception.

SS 24 (and presumably DUBV 24C) operates at 3 frequencies around 5 kHz, forming 24 beams (15 deg wide) using CW or FM pulses. Source level: 223 dB (ODT)/232 dB (RDT).

DUBV 24C is in the last 3 *Georges Leygues*-class frigates.

◆ DUBV 43

The towed VDS fish of the *Tourville* class generally operate in conjunction with a DUBV 23 hull sonar. Typical towing depth is about 300 m. Tow speed is 4–24 kt. The transducer in the stabilized fish has 24 staves (192 elements, 8 per staff). DUBV 43 can operate either independently or synchronized with DUBV 23, in scanning or in attack mode. The sonar operates on 4 frequencies around 5 kHz, with 15-deg beams (peak power 96 kW).

In the *Georges Leygues* class, the DUBV 43C is towed at more than 600-m depth. This increased depth adds 4 months to the period during the year when the sonar pair can cover the full depth of the Mediterranean. In addition, the "fish" tows a tactical array (TACTASS) 200 m aft. A second TACTASS is towed 3000 m astern of the ship, at a depth of 500 m. The TACTASS is fully digital, and it automatically tracks targets (presumably once they have been manually designated). The offensive element of this system is the Lynx helicopter; no Malafon is carried.

The DUBV 23/43 requirement was issued in 1963/64; Sintra-Alcatel used DUBV 24 as a building block. DUBV 43 was ap-

DUBV 43 fish, on board the experimental destroyer *La Galissonnière*. (U.S. Naval Institute)

proved for service in 1969, and an upgrade program was begun in the early 1970s. Tests followed in 1977, and the system was installed in 1978 on board the *Georges Leygues*. The last unit was completed in 1983, for the fourth C70-class corvette. In 1988 DUBV 43 was being modified for deeper operation, using a new transducer (developed by GERDSM), with a new signal processor (UTCS).

◆ DUUA 1A/B/C

This active searchlight sonar is found on the *Daphne* and *Agosta* classes. Beam is 8.5×8 deg. Frequency range is 13.5–30 kHz (6 bands); the high-power element operates at 17 kHz, with pulses of 8, 20, and 150 msec (power levels 100 or 400 W). There are 2-, 4-, and 6-km range scales. Passive operation is at 2–40 kHz. There are 3 versions of the transducer mount: MSS-1, -2, and -4. The transducer can scan manually or automatically. Automatic scan rate in azimuth is 15 deg/sec for MSS-1 and -2 and 30 deg/sec for MSS-4. Elevation limits are $-100/+30$ deg. There are 3 scan speeds (maximum 9 deg/sec) in MSS-1 and -2; MSS-4 does not scan. A is the basic version; B is a double sonar, and C is an intermediate sonar.

◆ DUUA 2

CIT-Alcatel's active submarine sonar is for the modernized *Daphne*, *Rubis*, and *Agosta* classes. DUUA 2 is a searchlight (beamwidth about 10 deg at 8 kHz) transmitting at 8 kHz (30 kW, 1.5 kW in reduced-power mode), with CW or FM pulses. Because DUUA 2 is a searchlight sonar, looking in only 1 direction at a time, each burst of pulses must be manually triggered. Pulse width is 30–500 msec, depending on mode. Range scales in active mode are 3, 6, 12, or 24 km. Displays are an A-scope (range vs. amplitude) and range-bearing. DUUA 2A scans at 4 or 8 deg/sec, between -175 and $+175$ deg, and its elevation angle can be set between $+15$ and -30 deg. The associated mount is MSS 5.

DUUA 2B is a passive adjunct, in a smaller sonar dome, operating narrow-band (500 Hz around frequencies between 2 and 15 kHz) and broad-band (2.5–15 kHz).

◆ DUUG-1/AUUD-1/Type 197 (Velox)/DUUG-2/DUUG-6

DUUG-1 is the first-generation Safare-Crouzet broad-band sonar intercept receiver; more than 500 were sold worldwide. The target's bearing is displayed on a CRT, and 1 loudspeaker provides audio warning. An associated system (AUUD-1B) measures the frequency of the intercepted signal. In a French *Daphne*-class submarine, the DUUG-1B hydrophones are located around the sail, on its fore and aft sides. This wide-band intercept receiver, without frequency analysis, gives only an approximate bearing.

DUUG-2 is in the *Agosta* and *Rubis* classes.

DUUG-6 (Velox M5) is a Safare-Crouzet stand-alone sonar-intercept system, intended to replace DUUG-1/AUUD-1/Type 197. Velox M6 is a similar unit intended for integration into a centralized combat system.

See also the private-venture Velox-M7 below.

◆ DUUX 2A/B/C

This passive range-finding system was developed in the late 1950s. A total of 120 were supplied to 14 navies for 8 different types of submarines. DUUX 5 is the successor.

The baseline (for 3 transducers on each side of the submarine) is 20–36 m, and the sonar operates on 5, 7, 12, and 18 kHz. Direction is determined by the delay (phase difference) in reception between the 3 transducers, as measured in a correlator/integrator, with the aid of variable delay lines. DUUX 2 covers a 90-deg arc on each side and achieves 1.5-deg accuracy in azimuth. Accuracy in range is 1% at 1–5 km, 2.5% at 5–10 km, 5% at 10–20 km, and 10% at 20–30 km. As of 1970, version A was in service, B was in preliminary production, and C was for the German navy.

◆ DUUX 5 (FENELON)

This third-generation passive range-finder replaces the earlier DUUX 2. DUUX 5 can be used as a stand-alone passive-search sonar, tracking up to 3 targets simultaneously; as a passive range-finder (by triangulation); or as a sonar-intercept receiver. In each case DUUX 5 measures both the frequency and bearing of intercepted signals and noises within a 2–15 kHz range. Displays include a 20-min track history of any target, to assist in classification.

DUUX 5 uses 2 arrays, each consisting of 3 hydrophones on 1 side of the submarine's hull. Range is by triangulation, and the target's course and speed are estimated by TMA. DUUX 5 automatically and continuously measures the bearing of any loud noise source near the submarine and calculates the range of up to 3 contacts in a 120-deg sector on each side of the submarine. A fourth target can be tracked by means of an acoustic

DUUX 5 array, 1 of 3 on each side of the submarine. (Thomson Sintra)

DUUX 5 display. Each half covers a 120-deg sector, with bearing running along the horizontal axis and time along the vertical. Radiated noise spectra can be displayed vertically on the right-hand side. (Thomson Sintra)

intercept receiver. DUUX 5 can listen on several frequencies between 2 and 10 kHz, and bearing resolution is 2 deg abeam and 4 deg at 60 deg fore or aft of the beam. Data can be transferred automatically to the submarine's FCS.

There are 5 standard alternative hydrophone units, ranging from 730 × 380 × 184 mm (DUUX 5-H1) to 1350 × 840 × 212 mm (DUUX 5-27H2). The latter version uses a beam-preformer (for resistance to countermeasures) with its large high-gain arrays (about 1 m², with 10-stave hydrophones).

DUUX 5 was developed for the French nuclear attack submarines. The contract to Sintra-Alcatel was let in the mid-1970s, the prototype being tested on board the submarine *Doris* in 1977. The first operational unit is in *Saphir*. A version of DUUX 5 is incorporated in the Eledone system.

◆ Diodon (TSM 2630)/Sorel (TSM 2630)

Thomson Sintra's medium-frequency sonar is for medium-sized ships. Diodon is the bow sonar, Sorel the same sonar in VDS form. They share common information handling and signal processing but can transmit separately. They operate at 11, 12, or 13 kHz, with pulses of 20 or 80 msec (CW or hyperbolic FM). FM pulses are pulse-compressed for reception. CW pulses are used for doppler processing. The stabilized transducer has 24 staves and uses 48 preformed beams for reception. Operating modes are ODT, RDT, SRDT (directional transmission confined to a sector), and SDT. Transmission can be at reduced power. Maximum power source level is 123 dB. There are 2 signal-processing modes: linear integration filtering (which can accommodate doppler speeds of up to 30 kt) and coherent processing (FM transmission, to reject reverberation). The coherent mode can show the fine structure of the target (range definition 1.5 m).

Generally all 24 staves are processed simultaneously (multiplexed). Range scales are 2–16 kyd. For attack, special precision circuits are used (range to within 1%, bearing to within 1 deg); data are displayed separately on a scope showing bearing within 10 deg to either side, and range within one-eighth of the chosen range scale, centered on the position of a surveillance marker on the main PPI. There is a separate doppler display (± 1 kt) for target following.

The signal processor can discriminate fast and slow targets (doppler). This sonar can be set for doppler enhancement (to eliminate reverberation) on 1 receiving beam, or on 2 adjacent beams for target following (beam comparison for accurate pointing). A target can be automatically tracked.

For the towed sonar, typical operating speed is 14 kt, and maximum towing speed is 20 kt. The fish is launched/recovered at 4–10 kt (10-min launch/recovery time).

Diodon medium-frequency VDS fish. (Thomson Sintra)

Diodon hull array. (Thomson Sintra)

Diodon employs the same display as DUBA 25 (Tarpon) and has the same function, but Diodon was intended to cost half as much: hence the choice of 24 rather than 36 staves, and the higher frequency for reduced size. Diodon was an early application of digital technology, for reduced overall volume, and has built-in fault-detection equipment that can isolate a fault to within 5 circuit boards. Estimated MTBF is 500 hr, and MTTR is 15 min.

Work began in 1969, and Diodon ran sea trials in 1971. TSM 2630 is an improved version (to which data above may refer). Diodon users: Argentina (A69-class corvettes), Ecuador (*Wadi M'ragh* class), Iraq (*Wadi M'ragh* class: TSM 2630 version), Libya (Vosper Mk 7 frigate and *Wadi M'ragh* class), Portugal (*Baptiste de Andrade* class), Saudi Arabia (*Al Madinah*-class frigates: TSM 2630 version).

◆ FENELON

See DUUX 5 above.

◆ FLASH

The Folding Light Acoustic System for Helicopters is a low-frequency helicopter dipping sonar that Thomson Sintra has offered for the U.S. ALFS, the Canadian NSA (New Seaborne Aircraft), and the European EH-101 and NFH90 programs. The associated processor can handle 8 or 16 sonobuoys. FLASH has 24 preformed beams and 3 frequencies (all below 5 kHz).

FLASH, showing the extended array and the winch assembly. (Thomson Sintra)

FLASH being tested on board a U.S. Navy helicopter. (Thomson Sintra)

◆ HS 12/SS 12/DIP 12/HS 312

Thomson Sintra's helicopter dipping sonar is the fifth generation this company has produced. HS 12 was developed from the company's SS 12 VDS for small ships.

HS 12 operates either actively (about 13 kHz, short CW pulse or FM slide) or passively (7–20 kHz), at depths as great as 300 m, with a figure of merit of 175 dB. The sonar employs 12 preformed beams, for a base directivity of 30 deg. However, the display consists of 4 quadrants, north-stabilized, each obtained by processing the 3 adjacent beams. In this panoramic mode the operator can select a CW mode, in which each quadrant shows the target's range and the target's doppler (speed range ± 40 kt). Alternatively, the operator can select FM processing (target range displayed precisely enough for the target's motion to be seen from sweep to sweep). There is also a sector mode for simplified target tracking, in which the 3 adjacent beams of the

sector are displayed. The manufacturer claims a maximum range of 10+ km. In the dip cycle, the winch operates at 5 m/sec (average). HS 12 can track 2 targets simultaneously.

Construction is modular, for quick installation; HS 12 can be removed from any helicopter in less than 45 min. Total weight is 508 lb (121 lb for the dome; 42 lb for a 300-m cable; 158 lb for the hydraulic winch; and 187 lb for the display, control panels, and black boxes). The sonar dome itself is 10.3 in in maximum diameter and 33.7 in long and weighs 16 kg [33 lb]. The manufacturer, Thomson Sintra, claims that HS 12 is currently the lightest helicopter sonar in the world.

As in the case of DUAV 4, HS 12 is attractive to have on board a large helicopter (Sea King, Super Frelon, or Puma) because it leaves space and weight for a large antiship missile (Exocet or, for India, Sea Eagle). This sonar can also be installed on board the AS 365F/565 Dauphin 2 helicopter in ASW configuration (in the alternative attack configuration, this helicopter carries 4 AS 15TT missiles).

DIP 12 was an abortive dipping version for surface-effect craft.

SS 12 is a hull and variable-depth searchlight sonar for fast attack craft and corvettes, operating in 3 frequency ranges around 13 kHz, using CW (rectangular or cosine-squared pulses) or FM pulses (source level 212 dB). SS 12 can automatically track 2 targets. The variable-depth fish can operate at 600 ft and at speeds of up to 16 kt; it can also be used with SS 24. Alternative range scales are 2, 4, 8, and 16 km or kyd. This sonar is comparable to the TSM 2640 Salmon, which has been more successful in its market niche.

HS 312 is essentially HS 12 integrated with a sonobuoy processor for 4 or 8 sonobuoys. Apparently, none has definitely been sold; probably all reported sales refer to HS 12. In some cases the original HS 12 may have been upgraded (FoM 177 dB). HS 312 was announced as the standard sonar of Super Puma naval helicopters, but they presumably carry HS 12 instead.

Reported HS 12 users are Chile (4 Dauphins, for which 20 Murène torpedoes were ordered in 1989), China (3, see below), Finland (2 on Super Pumas, others on Mi-8 and -14 helicopters), France (at least 30 on board Super Frelons and Lynxes, with more as DUAV 4 is replaced on board Lynxes), India (24 on Mk 42B Sea Kings), Indonesia (20 or 26 on board Pumas), Iraq (8 on

SS 12, the shipboard version of the HS 12 dipping sonar. (Thomson Sintra)

SS 12 fish (Thomson Sintra)

HS 12 on a Lynx helicopter. The dipping body and winch are on the left, the control panel on the right. (Thomson Sintra)

board Super Frelons, possibly others planned for 6 Super Pumas and 6 Dauphins on order in 1990), Portugal (5 Super Pumas), Saudi Arabia (12 on board Dauphins), and Singapore (on at least 5 of 22 planned Super Pumas). Other Super Puma naval operators are Brazil (6, plus 7 on order), Chile (3, plus 4 on order), Kuwait (6), Saudi Arabia (6), and UAE (8). Not all of these helicopters carry sonars. For example, the Chilean aircraft carry only Exocet missiles and VARAN radars (with TMV 026 ESM). The Finnish installation is interesting because other operators of Soviet naval helicopters may follow suit.

China bought 3 HS 312 (probably HS 12) sonars for Super Frelons. Reportedly, the 3 Super Frelons with HS 312s are prototypes for license production (under the designation Zhi-8) in China, so further sonars may be either on order or built locally. If the sonars really are HS 312s, that would seem to imply an additional sale of French sonobuoys.

HS 12 was first ordered in 1980.

Only 2 prototype SS 12s were built, and both were sold to the PRC in 1987. One is on board the Haijui-class patrol boat hull 688.

◆ Lamproie

Thomson Sintra's commercial towed array incorporates both wide- and narrow-band processing and automatic torpedo warning. The array proper is 74 m long, including the usual vibration-

Lamproie combined narrow- (top) and broad- (bottom) band display for initial detection. The upper display is a LOFARgram, showing frequency (horizontal) plotted against time (vertical). The graph below is a series of time integrals of the highlighted areas of the LOFARgram. The lower (broad-band) display is a waterfall, showing potential target tracks, bearing (horizontal) being plotted against time (vertical). (Thomson Sintra)

The Lamproie classification (LOFARgram) display, showing a series of 6 different frequency bands (separate horizontal bands) simultaneously. (Thomson Sintra)

Towed-array handling gear on board the frigate *Lamotte-Picquet*. (Thomson Sintra)

isolation dampers at each end. Diameter is 80 mm, and the casing is Kevlar. The array can be towed at up to 32 kt and at depths as great as 1000 m [3280 ft]. It can be towed by submarines (either in reel-in or clip-on configuration) and by surface ships (either in critical-angle or depressor-tow configurations, the latter for shallow water). The processor can operate simultaneously in several frequency bands, permitting comparison among different harmonics of the same signal, and the processor provides automatic threat (i.e., torpedo) warning while in the detection mode. Lamproie can track targets in either broad- or narrow-band mode, either automatically or manually, and can automatically reject narrow-band jammers. Classification resources are LOFAR, DEMON, and a special high-fidelity audio channel. The display is the usual pair of high-resolution color CRTs. This array is based on DUBV 62.

The wet end can be a critical-angle tow or it can be towed from a VDS fish.

◆ Salmon (TSM 2640)

Thomson Sintra's lightweight high-frequency towed sonar for small patrol ships is dismountable. The 24-stave transducer (diameter 290 mm, weight 150 kg) operates at 3 frequencies around 12 kHz (217-dB source level). The operating mode is ODT with CW or FM pulses (which can be pulse-compressed). CW pulses are used for doppler (spectral) analysis. The transducer produces

Salmon high-frequency VDS fish. (Thomson Sintra)

Salmon array. (Thomson Sintra)

48 beams with FM pulses or 24 with CW. Maximum instrumented range is 12 kyd.

This sonar can track 3 targets simultaneously, and Thomson Sintra describes its signal processing as particularly suited to shallow water with substantial background noise and reverberation. The techniques in question are pulse compression with a high compression ratio (for sharp discrimination in range); high doppler resolution in the CW mode; normalization (adjustable gain, to reduce reverberation effects); and computer-aided detection. A flexible display also aids the operator.

The fish lowers to nearly 300 ft. It can be streamed at up to 20 kt (typical operating speed is 14 kt), and launch/recovery speed is 4–10 kt (time 10 min). The fish weighs 550 kg, and the

towing/handling mechanical assembly weighs a total of 5.2 tons.

Development began in the late 1970s, the first unit being installed on board Swedish *Stockholm*-class fast patrol boats. Salmon was first tested in 1985. The *Göteborgs* are to have TSM 2643. Salmon has also been ordered for the Danish *Thetis* and *Flyve Fisker* classes.

◆ SPDT-1A

This passive broad-band preformed-beam sonar for surface-ship torpedo detection is made by Safare-Crouzet. Classification is by analysis of a torpedo's radiated noise. SPDT means *Sonar Passif pour la Détection des Torpilles*.

SPDT-1A is currently (1988) being installed on board the first of 11 major French warships. This sonar uses the array of an active hull-mounted or a towed sonar. SPDT-1A operates at medium frequency. The system reportedly detects a torpedo at 10 km or more under favorable conditions; it does not measure range.

◆ Spherion (TSM 2633)

Spherion array. (Thomson Sintra)

A Thomson Sintra VDS, Spherion is thus far in service only with the Norwegian and Indian navies. Spherion derives its name from its spherical shape. Like the much larger U.S. BQS-6, Spherion is covered with spot transducers, and presumably it can steer its beam both in azimuth and in elevation, for full 3D performance.

Derived from the TSM 2630, Spherion consists of 160 transducers on a 1.15-m sphere, weighing 1830 kg. This VDS operates at 10–13 kHz (on 3 or 4 frequencies), using 10- or 15-deg beams. Source levels are 217 dB ODT and 227 dB directional mode. There is also a sector directional mode. There are 36 preformed beams stabilized in azimuth and elevation; all CW beams are subject to spectral analysis (768 doppler channels), and FM pulses are pulse-compressed (TB of 300). The signal processor can extract and maintain 25 tracks simultaneously. Criteria provided by the system for target analysis include apparent length, inclination, and doppler. As in TSM 2630, the display incorporates 2 identical high-resolution monitors. Total system weight is 6000 kg.

Spherion was announced in 1985.

TSM 2633 is an ES/LF hull-mounted version, operating at 6–8 kHz, also producing 36 preformed beams, with instrumented ranges between 2 and 24 km. There is a VDS version of TSM 2633; it is not clear whether the higher-frequency Spherion de-

scribed above would be used as the complementary VDS. The Thomson Sintra brochure describing this sonar shows it installed on board what appears to be a Norwegian *Oslo*-class frigate, with a large spherical transducer in the bow sonar dome and a much smaller transducer in a towed fish. Reportedly, the new ANZAC frigate will be equipped with this Spherion B sonar. This sonar equips the last 2 Indian *Nilgiri*-class frigates.

◆ TSM 5421

Thomson Sintra's mine-avoidance sonar uses automatic mechanical scanning. It would typically be mounted in the upper bow of a submarine. Large obstacles are detected at 1000 m, and small ones (such as moored mines 1 m in diameter) at 600 m (12-dB reflection index). The sonar transmits a 30×15 -deg beam and receives using 10 preformed beams (each 3.2×15 deg). The entire transducer can scan mechanically (automatically) at 8 deg/sec to extend its search sector to a total of 60 deg (within about 4 sec) or 120 deg (within about 11 sec). The search sector can be moved over a 175-deg arc on either side, i.e., very nearly to dead astern. Range scales are 50, 150, 500, 1500 meters. There is also a passive mode (at 38 kHz) with audio presentation (beam 8×40 deg, directed on any manually selected bearing). This last mode is apparently intended for the reception of special pinger signals.

This is probably the mine-avoidance sonar of the standard current French integrated submarine-sonar suite.

◆ Velox-M7

This sonar-warning receiver for submarines is under development by Safare-Crouzet as a private venture, to replace Velox-M5/DUUG-6B. M7 automatically gives an alarm when sonar signals are detected, giving the bearing of the source and measuring the transmitter's frequency, relative level, pulse width, and PRF. M7 will also detect ultrasound communications and acoustic noise generated by surface ships.

◆ PVDF/PVF

In 1988 Thomson Sintra announced a new material, PVDF (polyvinyl fluoride), for passive sonar transducers. A continuous sheet of alternating piezo-electric film and metallic electrodes, to replace conventional ceramic hydrophones, PVDF is made in panels about 1.5×3 ft and about 2 in thick. It will initially replace conventional flank-array hydrophones; sea trials reportedly show a better signal-to-noise ratio (hence greater effective range) than conventional hydrophones, with useful response up to 5 kHz. Theoretically PVDF should be effective up to 10 kHz. This improvement is important because, given the baselines involved, ranging requires the kind of accurate bearing data available only above 5 kHz. Below that frequency the bearing of a target can be obtained, but individual flank hydrophones do not differ enough in their bearing data to provide range by triangulation. PVDF is already in service on board Norwegian submarines and is planned for French ballistic-missile submarines. Existing spot hydrophones have to be isolated from water flow over the hull to achieve sufficient signal-to-noise ratios. They are, therefore, mounted in fairings, and the fairings in turn cause drag as well as noise due to flow disturbance. The flat PVDF panels can presumably be mounted directly on the outside of a submarine's hull.

In May 1989 the nuclear submarine *Saphir* was fitted with Thomson-Sintra PVF flank arrays. These 5-cm-thick panels were developed specifically for the new *Le Triomphant*-class strategic submarines. A second version was to be fitted to a French nuclear submarine in the winter of 1990-91. See also the description of the test submarine *Le Dauphin*, below.

◆ New Submarine Sonars (Sonar Test Submarine)

The French diesel-electric submarine *Le Dauphin* was converted into a sonar test ship in 1983-85; all weapons were removed. She has tested a future spherical bow sonar, presumably a submarine version of Spherion. During 1989 she was fitted

with 2 types of hull side arrays and a long towed array. Both hull arrays are made of polyvinyl-fluoride (PVF2) extended-surface sensors. One consists of panels (several square meters each) with a complex acoustic structure. Its hydrophones are set against a rigid reflector elastically mounted on the pressure hull and flush-faired. The other is a pseudoconformal array distributed longitudinally over much of the hull to operate at VLF. As of October 1990, trials had been scheduled to begin in the fall of 1990.

UNDERWATER FIRE-CONTROL SYSTEMS

◆ DLA

Direction de Lancement d'Armes, a torpedo fire-control console for the Saudi *Al Madinah*-class frigates, controls 4 F17P wire-guided torpedoes fired from stern tubes. The console receives the essential data from the ship's combat system (target's bearing, range, heading, and speed); alternatively, DLA obtains these data directly from the ship's sonar. Two target tracks can be shown simultaneously, but only 1 torpedo can be controlled. If both targets must be attacked, 1 of the torpedoes must be fired on a preset track.

◆ DLT D3A

The standard French torpedo FCS is *Direction Lance Torpilles*. Versions in current service are the following:

D3A in *Agosta* class and modified *Daphne* class. All operations are controlled by an IRIS 35M computer. This version tracks 8 targets and guides 2 torpedoes while preparing a third for firing. The console has 3 displays, side by side: tactical situation, firing path, and an alphanumeric display of situation parameters (tote). There are 2 keyboards; typically, 2 operators sit at the console in the control room, with a third in the torpedo room. In recent installations the computer is a CIMS 15M125. This is the FCS installed in Spanish and Pakistani *Agosta*-class submarines.

L4C in surface ships.

S4E in *Daphne* class, controlling Z16, E14/15, and L3 torpedoes. S4D was in the modernized *Narval* class, now defunct.

Agosta CIC, showing the torpedo FCS display (DLT), DUUX 5, and the panoramic (integrated) sonar displays. (Thomson Sintra)

◆ SUBICS

This Thomson Sintra integrated submarine combat system is a follow-on to the earlier combination of separate sonars and the DLT D3A torpedo FCS; the latter already provided a tactical summary plot. SUBICS uses the new Colibri multifunction display consoles, with their 68000-series microprocessors; screens are up to 19 in in size. The associated sonars automatically detect and track targets, and TMA calculations are automatically conducted for all sonar tracking channels. Operators can interact with the TMA calculations to refine target data. Targets are identified by analysis of their radiated noise signatures, and also of their own sonar pulses (using a library look-up). The system can also use ESM and optronic-periscope data. Data from the different arrays are automatically correlated to form a single integrated picture, using data association and computer-aided data fusion. There is a large-screen command plot summarizing these data. Threat analysis includes torpedo alerts.

Details have not been published, but it would appear that SUBICS is a distributed system built along a data bus. In the past, 1 problem in such designs has been insufficient bus capacity to carry the very large amount of sonar data from the arrays (and preprocessors) to the consoles in the submarine CIC. A specialized cable can easily carry data from 1 array to 1 console, but true distribution demands that 1 bus carry all sonar data (as well as other data) simultaneously. This was 1 of the problems that killed the original version of the U.S. BSY-1. The published description of SUBICS suggests that Thomson Sintra plans to do much more of the processing at the array, without much human intervention, so as to reduce the load on the system bus (and also so as to make data fusion more practical). Such data reduction is probably also necessary if the central processing is to be done by a collection of 68000-series microprocessors. At least in the case of passive sonars, such automatic detection is still more an ideal than a reality.

SUBICS, then, represents a current universal ideal: to present the submarine commander, automatically, with a picture of the surroundings corresponding to the full set of sensors in the craft. The modular character of the system should make it amenable to changes in sonars and in weapons, the latter being particularly important given rapid developments in underwater-launched missiles.

GERMANY (WEST)

SONARS

Virtually all West German sonars are produced by Krupp-Atlas Elektronik GmbH (KAE).

◆ DBQS-21 (CSU 83)

Compared to the earlier CSU 3-4, this system adds a flank array and a towed array. CSU 83 is the primary sensor of the new German SLW-83 submarine's fire-control and command/control system now being developed, and also of the ISUS (integrated-sensor underwater system) for export. CSU 83 was evaluated on board a Type 206 submarine during 1985, the German navy ordering 13 sets for its SLW 83 integrated submarine combat system, 12 of them for Type 206A submarines being modernized and the other for a shore site. Others were ordered for the Norwegian *Ula* class, for the Swedish *Vastergotland* class, and for 2 Type 209s for Brazil.

The system consists of a passive bow array (0.3–12 kHz), a trainable active transducer (8 kHz, range 10 kyd, 30-deg beam), a passive flank array (10 Hz–2 kHz, range 50 kyd), a passive-ranging array (2–8 kHz, effective to 15 kyd), a towed array (100–800 Hz, maximum range 100 kyd), a sonar-intercept array (1–100 kHz, effective at up to 100 kyd), and 2 self-noise sensors (sail and machinery room, 0–12 kHz).

CSU is a commercial designation, meaning Compact Sonar for U-boats.

◆ DSQS-11

See the Mine Warfare section.

◆ DSQS-21/ASO80 Series

These are Krupp-Atlas's hull and variable-depth sonars for surface ships. DSQS-21A is for large destroyers. DSQS-21B for destroyers and frigates has 32 beams (variable-depth version has 64 beams). DSQS-21C for corvettes and DSQS-21D for small ASW patrol vessels have 32 beams in both hull and variable-depth versions. In each case a Z suffix, as in DSQS-21BZ, indicates that the transducer is electronically stabilized against roll and pitch. The transducer's diameter varies from 0.95 m (32 staves) in DSQS-21D, to 1.8 m (64 staves) in DSQS-21B, to 3.0 m (96 staves) in DSQS-21A for destroyers.

Console for a DSQS-21 sonar, showing a ray-trace indicator on the upper display and a PPI (plan position indicator) below it. (Krupp-Atlas Elektronik)

There are 5 selectable range brackets (2–32 kyd). Transmission modes are 5 and 50 msec CW; 50 msec FM; and 5/50, 50/50, and 300/300 msec CW/FM. The returning pulses are subject to processing optimized separately for each type (CW and FM) of pulse. On the PPI display, fixed navigational points (such as cliffs) are shown in yellow, approaching targets are in red, and retiring targets in green. In active mode, the sonar can automatically track 3 targets simultaneously, giving their range, bearing, and radial speed (i.e., doppler). In the passive mode, 3 targets can be tracked automatically in bearing. There is also a sonar-intercept facility. This sonar incorporates geometric processing, new plots being correlated with past tracks to reduce the false-alarm rate. The track list is constantly thinned by checking and by assigning each track a confidence level.

This sonar began with a German navy requirement for a sonar for the frigate (which became Type 122) that was planned for the 1980s; the export market was secondary. Krupp-Atlas began

feasibility studies in 1972. Bids were solicited in 1976, Krupp-Atlas carrying out R&D between 1976 and 1979, leading to tests of DSQS-21BZ in 1979. It is intended primarily to operate in shallow water, often with a cluttered bottom.

The export version of the DSQS-21 is the ASO80 (Type 80) series. ASO83 is a low-volume single-display system; ASO84 is DSQS-21; ASO85 has 64 preformed beams; and ASO86 has 96 preformed beams. There are variable-depth versions of each sonar.

ASO 84 to 86 are derived from DSQS-21; over 50 had been manufactured as of 1987, and all versions were compatible with a VDS. ASO83 is a smaller single-operator sonar intended for smaller surface craft up to corvette size. Dimensions are as follows:

	Hull Sonar/VDS Array Dimensions	Preformed Beams
ASO86	3.0/1.0 m	96/32 deg
ASO85	1.8/1.0 or 0.58 m	64/32 deg
ASO84	1.0/1.0 or 0.58 m	32/32 deg
ASO83	1.0/0.58 m	32/32 deg

Each has a stabilized beam option.

As of 1987, a total of about 50 DSQS-21s had been delivered to 15 navies. This sonar has replaced the U.S.-supplied SQS-23s of the *Lutjens*-class missile destroyers.

As of 1990, KAE claimed deliveries of about 60 DSQS-21s to at least 15 navies. That figure may include replacements for the SQS-23 sonars of the German *Lutjens*-class missile destroyers and the sonars of the *Bremen*-class frigates (11 ships in all). Reported export users:

KAE ASO 80 series: Argentina (10 MEKO frigates), Brazil (4 *Inhauma* class, ASO 84-2), Colombia (4 FS 1500 class, ASO 84-2), Malaysia (2 FS 1500 class, ASO 84-5).

DSQS-21: Nigeria (replaced PHS-32 in *Aradu*), Taiwan (10–15 DSQS-21CZ sonars in refitted non-SQS-23 destroyers and DSQS-21CZ for the modified *Perry* class) and Thailand (DSQS-21B in PFMM Mk 16s [*Ratanakosin* class]; DSQS-21CZ in the frigate *Makut Rajakumarn* [replacing PMS 26], in the U.S.-supplied PF 103 class [replacing SQS-17], in the new *Kamronsin* class, and in the last 2 frigates to be built in the PRC).

Most or all of the remaining exports are probably replacements for U.S.-supplied SQS-4-series sonars on board destroyers and frigates. Estimated unit cost is \$4 million.

◆ DSQS-23B/ASO 90

This is a new series of Krupp-Atlas active sonars to succeed the ASO 80 series. DSQS-23B is the sonar of the new F123-type frigates, and it probably corresponds to ASO 96.

ASO 90-series transducer. (KAE)

ASO 90-series active-sonar display, showing both a PPI and a B-scan centered about a bearing of interest. The circle at the very center of the PPI shows own-ship course and speed. (KAE)

	Hull Sonar/VDS Array Dimensions	Application
ASO 92	0.7 × 0.3 m (conformal)	patrol boats, corvettes
ASO 93	0.58/0.58 m	patrol boats, corvettes
ASO 94	1.0/1.0 or 0.58 m	corvettes, frigates
ASO 95	1.8/1.0 or 0.58 m	corvettes, frigates
ASO 96	2.5/1.0 m	destroyers, frigates

ASO 92 and 93 operate at high frequency; ASO 94 and 95 at medium frequency; and ASO 96 at low frequency.

The F123 sonar suite includes an intercept sonar and an active/passive towed array (with either a hull or a towed active transmitter).

◆ SLW 83/ISUS

This integrated sonar suite uses the CSU 83 (DBQS-21) sonar plus tactical data-handling and weapons control. ISUS (integrated-sensor underwater system) is the export version. Each sonar can initiate a target track, the data then being supplemented by data from the other sonars. Each track is subject to automatic classification and TMA (for up to 24 targets) before being combined with periscope and ESM data in the tactical data-handling system (TDHS). The TDHS in turn generates a combat-situation display. The system can handle up to 3 simultaneous engagements, either from a single console or from several consoles.

These systems are modular, built up from multifunction consoles: 2 for a small submarine or up to 6 for a submarine of over 1800 tons. German Type 206A submarines have 4 consoles, 2 devoted to the CSU 83 sonar suite, 1 to CIC duties, and the other to fire control. Each console carries two 15-in 3-color CRTs, the lower screen functioning as a PPI and the upper carrying alphanumeric tables.

The new Turkish Type 209/IKL 1400 submarines (the first of which was ordered in 1987) have CSU-83/1 sonar systems and KAE FCS, presumably of this type.

◆ CSU 2 and CSU 4

These searchlight sonars for submarines are tiltable and trainable. CSU 4 is an electronically scanned active sonar. These sonars are part of CSU 3-2 and 3-4.

◆ Krupp-Atlas CSU 3-2/CSU 3-4

An integrated sonar system for submarines, CSU 3-2 uses a fixed passive array and a searchlight active sonar that is mechanically tilted and rotated. Development began in 1963–64, and the first units (CSU 3-2 passive only) were installed in German Type 205

submarines in 1966–68, after which an improved version was exported. The AN526 passive array consists of a 96-stave horseshoe wrapped around the chin of the submarine, each stave consisting of 3 elements, and the entire array covering the sector back to 30 deg on each side of the bow. Beams are formed by delay lines. In service, it was soon found that individual staves could easily be knocked out of alignment and that they were difficult to replace.

Accuracy was about 1 deg. Hydrophone output was in 6 bands between 350 Hz and 3.2 kHz, all 6 being displayed above the main PPI as an aid to frequency analysis and classification.

CSU 3-4 is an improved version of CSU 3-2, with a circular passive array (3-m diameter, 900 mm deep). Because this array, which is designated AN5039, is more symmetrical than the chin array, its beam-forming network is easier to manufacture, and the array itself is easier to align. Type 205 and Type 206 submarines in Danish, German, and Norwegian service use the AN5039 chin array.

CSU 3-4 is specially intended for shallow water. Able to track 4 contacts automatically, this sonar system provides target elevation angle to estimate range and optimum sound ray path. An audio channel improves classification. The active mode is displayed in 30-deg sectors (waterfall) on the CRT, with continual memory update. The cylindrical array is electronically scanned. The intercept function can display up to 8 pulses in the center of the CRT, plus data on bearing, frequency, signal level, and signal duration on 1 pulse. These pulses can also be presented on the audio channel. Two passive-ranging sonars, PRS 3-4 and PRS 3-15, can be added as options. In 1987 German production shifted to the CSU 83, which combines active, passive, intercept, and 2 flank arrays, a doppler log, and an underwater telephone.

Reportedly, through mid-1988 KAE sold a total of 140 active, 144 passive, and 55 active/passive submarine sonars.

◆ CSU 3-41

CSU 3-41 is an active-passive sonar for submarines (in Canadian *Oberons*). The active transducer in the sail replaces the original Types 187, 197, and 719.

◆ CSU-83

This is the sonar suite of recent Brazilian, Norwegian, and Swedish submarines, as well as of modernized German Type 206s. It is intended for submarines displacing 500 tons or more; the smaller PSU-83 suite is for smaller units. CSU-83 incorporates the FAS 3-1 passive flank array as well as the cylindrical bow array and the trainable (over about a 30-deg sector) active transducer of earlier Krupp-Atlas sonar suites. There is also a sonar intercept receiver.

CSU-83 sonar coverage, including 3 passive-ranging arrays on each side. (KAE)

The associated sonar-information processor is generally the Atlas SIP 3.

◆ CSU-90

This is a new-generation submarine-sonar suite. The basic version consists of a passive scanning attack sonar (a 2.8-m cylindrical array with DEMON processing), a passive intercept sonar, and a low-frequency (i.e., long-range) flank array. The cylindrical array operates on both direct and bottom-bounce ray paths. Any target detection by 1 of the 3 elements initiates automatic data collection and compound track formation. There are 8 ATT channels for the attack sonar and 8 ATT channels for the DEMON analyzer (each with 8 ALTs [automatic line trackers]). An optional TMA controls 8 compound tracks and a sonar tactical-situation display, and it can control further manual tracks. Finally, the flank array has 8 ATT channels and 8 MLTs (multiline trackers), each with 8 ALTs. The system associates tracks from the different sensors to form up to 8 full compound tracks. All compound tracks can pass through the optional TMA analyzer; the analyzer can also evaluate other sensor data to form a more complete tactical picture, which is displayed on a tactical-underwater-situation display (TUD) associated with the TMA option.

The other optional add-ons are: passive-ranging sonar (PRS), own-noise analyzer (ONA), acoustic passive classification (APC), automatic warning channels (AWC), a disk mass memory unit (DMU), and plotters and simulation facilities. The disk holds data for comparison purposes (for the SIP) and the classification file for the intercept sonar, and it carries the interface to the plotter.

The system uses EPR 2300 32-bit processors (using 68030 chips) and the new standard 2-screen console described in the Surveillance and Control section of this book. Only 70 different computer boards are used for the total of 500 boards in the system.

◆ ELAC 1BV

ELAC 1BV was the first modern German-produced surface-ship sonar; it is installed on board the *Hamburg*-class destroyers and the *Thetis*-class corvettes (the contemporary *Köln* class have the Dutch PAE/CWE combination). This sonar was reportedly also installed on board early Israeli *Saar*-class attack boats, and there has been speculation that it is the sonar for which the Spanish *Lazaga* class is fitted.

This is a biaxially stabilized searchlight sonar, trainable and elevatable. There are consoles for target direction, elevation angle, doppler/range, and coarse doppler/range. The target-elevation-angle measurement was necessary for the sonar to control the Bofors ASW mortar mounted in the 2 classes of German ships.

There were several versions. Some of the data below are from official data sheets prepared in 1973 and 1979 (the latter for 1BV/2). However, the official specification for ELAC 1BV2 is dated December 1965 (revised to February 1966). These are all magnetostrictive sonars.

The sonar originally operated primarily at 18 kHz (alternatively, at 12 or 15 kHz). When the transducer was enlarged (for the 1BV2 version), primary operating frequency was reduced to 10 kHz (it could also be set at 12 or 15 kHz) because otherwise the beam would have been too narrow to be tactically useful. ELAC also proposed an 8.2-kHz version. The other major improvements made at this time (1965) to both 1BV and 1BV2 were automatic sum-difference reception (for target following), transistorization, own-doppler compensation, sonar self-test, and a heater for use when the sonar was not operating. These sonars have a sector-scan mode (both vertical and horizontal), the scan rate being set by sector width and by range scale.

ELAC 1BV/1 operates at 14.9 kHz (5–50-msec pulses, 4 kW). Range scales: 1500, 3000, 6000, 9000 m. This sonar could operate with either of 2 FCSs, 9 AU 101 or M5/4 (the former a PEAB, the latter a Signaal system). Data sheets show the 9 AU 101 version operating at 14.9 kHz, the M5/4 version at 12.05

CSU-90 sonar suite. (KAE)

kHz. Source levels: 123 dB at 12 kHz, 124 dB at 15 kHz, 125 dB at 18 kHz. Beam widths at these frequencies: 14, 10, 9 deg, respectively.

ELAC 1BV 1A equips the 4 *Hamburg*-class destroyers and was fitted to the training ship *Deutschland*. Of these ships, the destroyer *Bayern* is fitted with the 15-kHz version and *Hessen* with the 18-kHz version; the others have the 12-kHz version. The trials ship *Hans Burkner* is fitted with 1BV 1B (15-kHz version).

ELAC 1BV/2 is an improved 1BV with higher power and with a transducer of about 4 times the area of the earlier version. It operates at 10.0, 12.05, or 14.9 kHz (fixed in each case) with peak power increased to 16 kW (but switchable to $\frac{1}{3}$ or $\frac{1}{10}$ power). Pulse width is 5–50 msec, and range scales are 1500, 3000, 6000, and 12,000 m. This version uses 2 transmitters (normal search and high power), and it is not clear whether it was associated with the 9 AU 101 FCS or with M5/4. Source levels: 131.5 dB (8.2 kHz), 133 dB (10 kHz), 134.6 dB (12 kHz), 136 dB (14.9 kHz). Beamwidths (at 3 dB points) at these frequencies: 12.6 deg, 9.6 deg, 8 deg, 7.5 deg. The 8.2-kHz version did not enter service.

ELAC 1BV2 was installed on board the *Thetis* class (2 at each frequency).

An ELAC 1BV3 was also reported, operating at still lower frequency (6.8, 8.2, or 10 kHz) but with lower peak power and with pulses closer to fixed length (20–25 msec). No applications have been reported.

ELAC (Electroacoustic GmbH) is now a division of Honeywell and no longer produces complete sonars.

◆ FAS 3-1

Krupp-Atlas's passive flank array for small diesel-electric submarines operates over the 10 Hz–2.5 kHz range. One array

(either 20 or 48 m long, depending on the length of the submarine) is mounted on each side; a 30-m array is typical. Each contains 90 staves, for a total of 288 hydrophones. Typical accuracy is 1 deg for targets in the 90-deg sector centered on dead amidships, with lesser accuracy for bearings closer to the centerline, down to within 10 deg of dead ahead or astern. FAS 3-1 is part of the current Krupp-Atlas sonar suite, CSU-83.

◆ ISUS

This is the display and combat system associated with the CSU-83 suite. ISUS consists of a number of Multifunction Capability Common Consoles (MFCCs) linked by databus to transfer all digital, video, and audio signals within the CSU-83 system. The associated sensors are the attack, towed-array, flank-array, passive-ranging, intercept, and passive/active operating sonars and periscopes, ESM, radar, and navigational sensors. The color-coded raster-scan displays are interchangeable between the MFCCs. Design objectives include automatic interactive detection, tracking and analysis of all acoustic signals, automatic classification and contact-motion analysis, threat and combatability analysis, and optimized control and guidance of several types of weapons. All the important processors have battery-buffered memory to guard against temporary loss of power. The system provides panoramic passive detection (PPD) of targets, measurement of bearing and level of target noise over the whole horizon, complemented by ATT information fed to the WCS. A hard copy of the ATT data is provided in the form of a time-bearing plot. The associated sonar-intercept system measures bearing, amplitude, frequency, pulse spectra, modulation type, pulse length, and PRF.

Reportedly, the multifunction consoles are the same as the standard German type now being used in the Type 123 frigate and in the CoSYS 200 CDS (see the Surveillance and Control section).

The basic version, suitable for a small submarine (less than

ISUS, showing the multifunction consoles (bottom). (KAE)

OSID configuration. (KAE)

The ISUS tactical display (synthetic-video PPI) shows target tracks (including ping histories). The small circle to the left is the contact being tracked (its parameters—bearing, range, course, speed—appear on the right). (KAE)

500 tons), supports an attack sonar, intercept sonar, ESM, and radar with 2–3 MCCs. The next step up, adding passive ranging (500–1000 tons), adds another MFCC. Adding an active sonar and a flank array (1000–1800 tons) adds another MFCC (total 4–5). A larger submarine (above 1800 tons) would support a towed array, requiring an additional MFCC.

◆ OSID

OSID is the CDS associated with the PSU 83 compact sonar. It has 2 consoles, 1 for sonar and 1 for torpedo control. Functions are north-stabilized multibeam processing, ATT, and bearing/

OSID threat-evaluation display, showing a calculated torpedo-intercept path. (KAE)

time recording for up to 120 min. The weapons-control Tactical Data-Handling (TDH) function provides target motion and threat and attack analysis. The torpedo-control functions are torpedo preparation, launching, and guidance. In effect, OSID replaces the existing Type 209 systems with new preprocessors and new consoles (including beam-formers).

◆ PRS (Passive-Ranging Sonar)

PRS is a passive complement to CSU 3-4 active/passive sonar. There are 2 types of PRS 3, each with 6 sets (3 each side) of hydrophones. Each PRS 3-15 array has 60 hydrophones in 15 staves; each PRS 3-4 array has 40 smaller hydrophones. Tracking can be either manual or automatic, following 4 targets simultaneously in manual mode. For automatic tracking, the system uses the ATT channels of the CSU 3-4. Targets can be tracked over a 170-deg arc on either beam (45–135 and 225–315 deg relative to the bow). Targets are tracked at 2–8 kHz. The combination of large arrays and a wide frequency range makes for an accuracy of about 0.5 deg over the highest performance arcs (45–135 and 225–315 deg) of PRS 3-15.

PRS 3-15 can track up to 4 targets automatically, measuring their ranges and calculating course and speed. Range is determined from the curvature of the wavefronts coming from a target, as in the U.S. PUFFS system. KAE claims that interference effects and other disturbances common in narrow-band systems are suppressed by using wide-band preformed beams. The processor calculates correlation functions between the amidships and end arrays and uses these functions to calculate time delays and then ranges. The variance of the time delay is used to estimate a range of confidence for the range estimate.

Smaller submarines can be fitted with a less elaborate passive ranging, with as few as 5 staves per array.

The overlapping preformed beams of PRS 3-15. (KAE)

A typical PRS 3-15 ranging display. (KAE)

A PRS sonar can be used as an independent sensor (for detection, automatic tracking, ranging, and course and speed evaluation), or the sonar can be controlled automatically by the main sensor's automatic tracking channels, to measure range and evaluate a target's course and speed.

This system, roughly contemporary with CSU-4, was developed in 1961–65 and tested in 1965–66.

◆ PSU 1-2

This sonar for small submarines was developed for passive detection and reception of underwater telephone signals. PSU 1-2 uses a cylindrical transducer with 64 preformed beams, presenting information on a CRT in true or relative bearing. PSU 1-2 can autotrack 4 targets and is intended for a 400–500-ton submarine. Two targets can be transferred to the FCS and 1 target to the plotting table. Selected parameters are displayed on the associated digital indicator (TPD 3). The operator classifies the target by listening on the audio channel, the reception direction of which is coupled to the bearing cursor.

System set-up

PSU 1-2, the simplest system in the KAE series. (KAE)

CRT display

A typical PSU 1-2 passive display, showing 3 targets.

◆ PSU-83

This sonar suite is for smaller submarines (500 tons and below) and to update existing units, working with the OSID tactical system. PSU-83 employs a conformal bow (chin) array and a semicylindrical aft-looking array (e.g., in the base of the sail), with a single display console. KAE offers a new programmable

PSU 83. (KAE)

and north-stabilized beam-former suitable to a variety of other existing arrays, so that the electronics of PSU-83 can be used for submarine modernization.

PSU-83 supports 8 independent simultaneous 2-mode ATT channels. It includes a sound-ray tracer and sound-distribution display. Target bearings are constantly predicted for emergency snap-shots, and bearing rate is measured on the electronic waterfall (bearing-time) display. The signal processor filters out intercepted sonar pulses and own-noise and also has separate selectable filters. The display is a color raster-scan CRT. There is a high-quality audio channel for classification.

Options: intercept sonar; flank array (using LOFAR processing); DEMON detection, tracking, and analysis; active pinger; passive ranger (PRS); own-noise analysis (ONA); mass storage for target data and display recording; sonar graphic recorder (bearing-time and frequency-time waterfalls); and on-board sonar trainer.

PSU-83 and the FCS FSU 83 form the submarine combat system OSID 83.

◆ SIP 3

SIP 3 is the current KAE sonar processor, for use with the fast-scanning multitarget-tracking sonars of CSU series. It is primarily for target classification, based on low-frequency detection and analysis. DEMON is used to extract low-frequency spectral information from relatively high frequency target noise. SIP 3 incorporates sound-ray path analysis. It can process up to 4 targets simultaneously, presenting them 1 by 1 on the screen. Evaluation modes: spectral analysis in various bands; automatic line tracking (ALT); automatic maneuver detection (AMD); high resolution of target bearing; ATT of targets set by the sonar, including situations when targets cross; range, bearing, and doppler measurement in the active mode. Data can be digitally recorded for later comparison with a data base.

◆ TAS 83

This KAE submarine towed array is compatible with the CSU 83 system. Presumably, it is related to the array that the new Type 212 submarine will tow. There are 2 alternative clip-on wet ends, and the inboard electronics can be varied. As of 1990, TAS 83 had already been tested at sea.

◆ TASS 3-2

Krupp-Atlas is developing a towed array for German surface combatants; it will become operational, on board Type 122 and Type 123 frigates, in 1997. In theory, this array should differ from those developed for other navies since the German navy optimizes its ships for the relatively shallow waters of the Baltic and the North Sea.

As of 1990, TASS 3-2 already exists at least in a test version. The system consists of the sonar proper, TAS 3-2, and the handling system, TAMS 3-2.

TAS 83. (KAE)

FIRE-CONTROL SYSTEMS

◆ Hagenuk's Torpedo FCS

Hagenuk's torpedo FCS was developed for the first postwar German torpedo boats, Types 140 (*Jaguar* class), 141, and 142 (*Zobel* class), some of which survive in Greece, Saudi Arabia, and Turkey. The Hagenuk system controlled unguided forward-fired Mk 8** (British-supplied) torpedoes. It used an optical target designator (*Zielsaule*); the target angle and torpedo spread angle were cranked in centrally and corrected separately for each tube (typically, the forward tubes were splayed 9.5 deg from the boat's centerline, and the after tubes 15 deg from centerline). Torpedoes could be fired in salvo, either all 4 at a time or 2 (fore or aft groups) at a time. It is not clear whether target data were entered automatically from the ship's plot (CIC), which accepted radar and own-ship data. The maximum torpedo gyro angle was 30 deg. The personnel required were 2 at the target designator, 2 at the tubes (presumably, the system was follow-the-pointer rather than fully automatic), 1 at the plot, and 1 at the radar.

Although the German-built boats are sometimes credited with wire-guided torpedoes (such as SEAL), they carry forward-firing tubes that probably cannot fire such weapons; they probably still rely on the Hagenuk (rather than the more complex Signaal M11) FCS. Type 140/141 was also built for Indonesia (they are now extinct), and Type 142 (TNC 45) for Turkey (under a NATO contract, as the *Kartal* class) and for Saudi Arabia. German Type 141s were transferred to Turkey in 1975–76 and to Greece in 1976–77. Some German Type 142s (now extinct) were rebuilt with Signaal FCSs and with aft-firing tubes for German-type wire-guided torpedoes.

INDIA

◆ APSOH

Bharat Electronics's Advanced Panoramic Sonar was first installed on the Indian frigate *Himgiri*, presumably in place of a Canadian Westinghouse SQS-505. APSOH also now equips the second and third *Godavari*-class frigates. APSOH has been described as an ODT scanning sonar, developed by the Naval Physical and Oceanography Laboratory (NPOL) at Cochin. Presumably, it is comparable to (or similar to) SQS-505.

ITALY

SONARS

◆ IP-64

This integrated active/passive sonar suite of the *Enrico Toti* class incorporates a JP-64 active sonar. IP-64 is an analog system; about 1982 the Italian navy drafted a staff requirement for a digital upgrade, retaining the same array but replacing the

existing operator console with 1 based on that of the NA-18 AAW FCS.

The system consists of a conformal passive array on the chin and an active circular array on deck. A passive range-finder (MD-64, consisting of 3 hydrophones on each side) can be added. Operation of all 3 units is analogous to the IPD 70 system, the submarine using her conformal array and her passive ranger to get into attack position and then obtaining a final range by single ping. As in the MD-70 system, MD-64 can lock onto a signal to produce continuous bearing data.

◆ IPD 70/S and SISU

IPD 70 is the integrated active/passive sonar of the *Sauro* class, using much IP 64 technology and, therefore, largely analog. IPD 70/S is a digital version for later ships of this type, the existing 2-operator console being replaced by a console based on that of the NA-18 AAW FCS.

There are 3 arrays: a conformal array of 46 barium titanate hydrophones wrapped around the lower part of the bow, for long-range detection and classification (220 Hz–7 kHz); a 36-stave cylindrical HF array in the upper part of the bow for target tracking (8–15 kHz); and (optionally) a pair of line hydrophones down the hull for passive ranging (designated MD100/S when used alone). The HF array can track 4 targets simultaneously; the passive linear arrays can range up to 3 noisy targets. Targets are tracked passively, and accurate ranges are then obtained by single narrow-beam (10-deg) HF pings (peak power 10 kW, source level 130 dB). The same array can be used for active search (ODT or RDT) if required. There are 2 sonar interceptors: 1 using the main passive array (3–15 kHz), and the other a Velox M5 (see the French entry above for details) operating in the 2.5–80-kHz range, primarily to detect active-homing torpedoes approaching from abaft.

These sonars are made by USEA/Selenia. In export form they are designated SISU-1; SISU-2 is a modified version for small (600-ton) submarines. The SISU-1 designation has also been used for the FCS of the *Sauro* class (see SEPA, below).

The IPD 70/S can be integrated with the IN100A omnidirectional and directional LF intercept sonar, ISO100 omnidirectional HF intercept sonar, TS100 underwater telephone, and CM10 acoustic range predictor.

IPD 70/S transducer. (USEA)

◆ MD 100/S

MD 100/S is an update of Selenia-Elsag's M100 passive range-finder for small to medium diesel-electric submarines. MD 100/S can operate separately or as part of IPD 70/S. MD 100/S employs 2 linear arrays, each consisting of 3 equally spaced transducers on the port and starboard sides of the hull, and can track 4 targets simultaneously within 60 deg of amidships (to either side). This sonar triangulates to obtain range and bearing on each target, using at least 2 transducers on either side, then

uses TMA for the target's course and speed (either using own data or data from another sonar). The modification program parallels that of IPD 70/S. Trials were conducted in 1981–83, and this system is installed in Improved *Sauro*-class submarines laid down from 1983 on. MD 100/S is being retrofitted in earlier Italian *Sauro*-class submarines.

◆ New Sonar Suite

ELSAG and USEA are developing a new submarine-sonar suite, including a towed array, for the next-generation Italian navy submarine (S-90). The towed array will be developed with foreign assistance (this program is already in progress). The hull sonars will operate at lower frequencies, all the acoustic sensors using a common redundant processor. The single processor will automatically correlate signals from the various arrays, and it is to incorporate AI for automatic target classification. The new suite will be integrated with the SICS (Submarine Integrated Combat System) being developed by Welse, using standard MAGICS displays.

FIRE-CONTROL SYSTEMS

◆ DLB-1

DLB-1 is San Giorgio-Elsag's analog AWS FCS, used to control the K-113 (Menon) depth-charge mortar and lightweight ASW torpedoes. DLB-1 accepts scanning sonar data and generates a solution, which is transmitted to the sonar for rate-aided tracking (as a check on the solution). DLB-1 also stabilizes the sonar. The system provides an ASW tactical display on the bridge, and it incorporates a Fire Pattern Programmer that can vary the pattern of shots by the mortar. Design studies began in 1964, and DLB-1 was first fitted on board the corvette *de Cristofaro* in 1965; 12 were made. The mortar considerably preceded the appearance of the DLB-1 system; it was presumably retrofitted on board *Centauro*- and *Bergamini*-class frigates.

◆ BSN-716 (SACTIS)

SACTIS is the standard current Italian navy integrated submarine combat system, using a single central computer (in this case a Rolm MSE 14 with disk memory). The associated sensors are the IPD-70 sonar, Thetis ESM, and BPS-704 radar. Made by SMA, SACTIS incorporates the Elettronica ELT/810 sonar-performance predictor. There are 2 display groups (each with 3 screens). Each display is a 9 × 16-in CRT, and up to 30 targets can be displayed simultaneously. Individual track histories can be selected for presentation, with 10 available as filtered targets. There are 4 presentations: the general unfiltered situation; a tactical picture; a time-bearing display; and TMA. Sonar-ray paths can be displayed, and own and target's sonar performance calculated. SACTIS can also accept both manually entered and Link 11 data.

The *Sauro* class FCS can track 4 targets simultaneously.

SMA was selected in 1981 to develop BSN-716(V)1 and -716(V)2 for the second and third batches of *Sauro*-class submarines. These systems are offered for export as SACTIS (Submarine Action Information System) 1 and 2. SACTIS 1 has 2 consoles and a computer (a Rolm MSE 14). SACTIS 2 adds a third console and has more computer power for real-time TMA calculations.

◆ SEPA FCS Mk 3

SEPA is *Societa di Elettronica per l'Automazione*, part of the FIAT group. This and other SEPA systems are based on standard ULP series mini- and microprocessors. FCS Mk 3 is the torpedo and weapons control subsystem of the larger SICS system described below. It functions as a command/control system, predicting acoustic sensor performance so that it can interpret sonar data for TMA; it also predicts counter-detection range and conducts threat evaluation and target designation. The fire-control portion of the system guides up to 6 A184 torpedoes.

Each of 3 consoles contains a circular main CRT, with 2 rectangular screens alongside (1 can be a touch-screen for com-

puter-defined action keys). These consoles are also used in the SICS system. The computers are militarized ULP microprocessors, built by SEPA.

SEPA Mk 2 is a corresponding surface ship ASW FCS.

Peru ordered SEPA Mk 3 (and A184 torpedoes) for its Type 209 submarines in June 1986, to replace the earlier M8 and SINBADs systems. A modified version, FCS Mk 3, is used as a backup to the BSN-716 system of *Salvatore Pelosi* (modified *Sauro*)-class submarines.

FCS Mk 1 is the system in the *Sauro* class, with a 2- (rather than 3-) CRT console (computation, display, and control station, or CCRG) built around a ULP 12/M minicomputer. Unlike Mk 3, Mk 1 has no small rectangular auxiliary screens (it uses arrays of single-purpose buttons). This system can handle 4 targets simultaneously; presumably, each circular CRT can handle 2 targets.

FCS Mk 2 is the corresponding surface-ship ASW FCS for A184 torpedoes on board *Audace*-class destroyers and *Maestrale*-class frigates.

◆ SICS

SICS (Submarine Integrated Combat System) is being developed by a consortium of Eltag, Whitehead, and SEPA (the Welse consortium). Like SEPA Mk 3, SICS uses several interchangeable consoles, which incorporate the system's computers.

SICS differs from SEPA FCS Mk 3 in processing sonar data directly; in the simpler system, sonar data are processed elsewhere. In addition, it provides command and common submarine services (such as navigation) that are not carried out by the FCS. A typical SICS would use 5 standard consoles, each with a pair of rectangular CRTs, lying on a data bus.

JAPAN

Japanese submarines are equipped with license-built U.S. SQS-36J active sonars. Some surface ships have SQS-35J VDS.

Development of a new tactical towed array, OQR-1, with performance to be superior to that of the U.S. SQR-19, was announced in JFY86. R&D work on a high-speed low-noise towed array began under the JFY87/88 program. There is also a surveillance towed-array project. A submarine-towed array, included in the ZQQ-5B system, was tested on board the submarine *Okishio* in 1987. In addition, work is proceeding on an

improved LF active sonar, using a new transducer and improved anechoic baffling.

Work is proceeding on a new long-range active sonar and on passive and active towed arrays, as well as on submarine-combat-system automation, including applications of artificial intelligence. The contractors are Mitsubishi and Kawasaki.

◆ HQS-101

The dipping sonar for the PS-1 maritime-patrol aircraft operates at 5 kHz. PS-1 is unusual in that it lands to dip its sonar before attacking; other patrol aircraft merely drop sonobuoy fields. The -101C version solves the problem of noise interference (from the airplane's engines) by noise cancellation.

◆ HQS-102

This is the dipping sonar of Japanese Sea King helicopters, comparable to the U.S. AQS-13. It may actually be a license-built AQS-13 (many writers claim that the Japanese Sea Kings are equipped with the latter, and that was certainly the case with early ones).

◆ OQS Series

The OQS Series are hull sonars for surface ships:

OQS-1/2/12/14 are license-built versions of the U.S. SQS-4/29; OQS-12 and -14 are developed versions, in the *Isuzu* class. OQS-12 is a modified SQS-31. Like some U.S. versions of SQS-4, OQS-12 or -14 can support a VDS operating from the same sonar stack, using an OQA-1 hoist and fish equivalent to the U.S. SQA-10 (*Isuzu* class). The current VDS is SQS-35J. In *Shirane*, the VDS is used to tow an array.

OQS-3 is a license-built SQS-23 bow sonar. It is being replaced by OQS-4.

OQS-4 is an indigenous LF design, in the *Asagiri*-, *Hatakaze*-, and *Hatsuyuki*-class destroyers, and the *Yubari*- and *Ishikari*-class frigates. OQS-4 is probably similar to SQS-23. Compared to OQS-3, OQS-4 has improved electronic components and better signal processing.

OQS-101 is an indigenous-design hull sonar, equivalent to U.S. SQS-53. OQS-101 is the hull sonar of the *Shirane* class and will be used in the Japanese Aegis destroyers.

OQS-X is a new hull sonar for the new Aegis destroyer, now under construction.

An *Uzushio*-class submarine shows the characteristic cylindrical transducer of recent Japanese submarine sonar systems. (*Ships of the World*)

◆ Submarine Sonar and Combat Systems

From the sixth submarine in the *Uzushio* class (*Takashio*) onward, the separate TDC was eliminated in favor of a system in which detected target data are processed digitally and shown on a CRT. In the *Yushio* class, the computer/display system, ZYQ-1, is greatly enlarged. For the first time in a Japanese submarine, it automatically links detection and weapons systems. It also handles submarine operations data. The system is also described as the SCDS, or submarine computer data system. Installation of ZYQ-1 required an additional 350 tons of submarine displacement (from the 1850 tons of the previous class to 2200 tons). From the *Nadashio* on, Harpoon fire control is added to the computer system. The new *Harushio* class will have a new version of the basic system, presumably ZYQ-2. Growth to 2400 tons accommodates decoys and a towed array.

ZYQ-1 in the *Uzushio* introduced a new Japanese-produced sonar array, a 10-ft diameter DIMUS cylinder consisting of 3 tiers of staves, in the bow of the submarine. The system is used for search and for precision (presumably passive) ranging and as a sonar intercept receiver. The *Uzushio* has been broken up, and the other unit with this sonar, *Makishio*, is a target services training ship. ZYQ-1 and its successors are manufactured by Oki Electric.

ZYQ-2, a modified ZYQ-1, was introduced in the *Isoshio*, the third unit of the class. Three submarines of this type are in service, 1 (*Isoshio*) as a training ship.

ZYQ-3 was introduced in the *Takashio*. She and later submarines have an MF active sonar, SQS-36(J), midway up their sails, to supplement the bow sonar.

ZYQ-4 was introduced in the *Yushio* class. In 1987 the *Okishio* of this class was the first Japanese submarine with a clip-on towed array, a purchased U.S. BQR-15. It will also be fitted on 3 other *Yushio*-class submarines. In these submarines the active sonar is closer to the base of the sail, below the sail planes. Like the earlier sonar systems in this series, ZYQ-4 employs a cylindrical bow array.

ZYQ-5 is for the new *Harushio* (2400-ton) class; it will be a new type of system, combining a bow array with a flank array and a Japanese-produced retractable (rather than clip-on) towed array. From the second unit on, the system will be the modified ZYQ-5B. This class will also be fitted with a torpedo decoy system.

NETHERLANDS

In 1990 the Signaal sonar division was amalgamated with that of Thomson Sintra; the Signaal surface-ship sonars are no longer offered for sale as such.

SONARS

As of 1989, Signaal was working on an advanced Type 209 sonar update, as well as on new sonar configurations for 2 NATO navies.

◆ CWE-10N

This 10.5- or 11-kHz searchlight surveillance radar is installed on board the German and Turkish *Koln*-class frigates and on board the ex-Dutch cruisers and destroyers in Peruvian service; CWE-10N may still be on board the Argentine carrier *25 de Mayo*. In German service, CWE-10 is associated with the Signaal M5/1 FCS. Pulse width 0–50 msec (also reported as up to 100 msec); instrumented ranges 1, 2, 3, 4, 6, 8, and 12 km; peak power 10 kW.

The manufacturer was van der Heem, part of the Philips group, which was later absorbed into Signaal. In destroyers and frigates, this sonar was associated with PAE (see below). Total installation weight was 3200 kg, compared to 3800–6000 kg for the contemporary ELAC 1BV series.

◆ LWS-20

Signaal's sonar-intercept device uses 4 arrays to cover the four 90-deg sectors, the whole device being diagonal to the centerline of the submarine. Each face carries 4 hydrophone groups, for the 4 bands in the 2–80-kHz range. The display consists of 2 CRTs, 1 for bearing and 1 for frequency, plus 15 LEDs to give signal strength (which provides a measure of range).

This device appeared in the early 1960s.

◆ LWS-30

The Signaal (HSA) passive sonar and sonar-intercept system for submarines was announced in 1973. LWS-30 could use existing transducers and hydrophone arrays. Capabilities included omnidirectional warning and multitarget autotracking, as well as torpedo warning.

Frequency ranges were: CRT display for 1.25–80 kHz (sonar intercept); torpedo warning for 20–80 kHz; direct audio for 1.25–10 kHz (synthetic audio produced for 10–80-kHz signals). All signals (1.25–80 kHz) are displayed on a CRT and are measured for analysis. The system was designed to track signals in 3 ranges: 1.25–2.5 kHz, 2.5–5 kHz, and 5–10 kHz.

Intercept ratio: between 1.25 and 10 kHz, 12.5:6 at 5-kt speed in sea-state 3; 9.5:5, when snorkeling. Between 10 and 80 kHz the respective ranges of intercept ratio are 5.5:3.5 and 5:3.

Detection range: 1.25–10 kHz at 5 kt in sea-state 3, 125–40 kyd, snorkeling, 100–35 kyd. At 10–80 kHz, 25–6 kyd at the lower end of the band and 20–6 kyd at the upper end. Signaal offered a 600-kg LF hydrophone array (height 800 mm, diameter adapted to ship dimensions) and a 40-kg HF array (200 mm × 280-mm diameter).

◆ PAE-1

Van der Heem's attack sonar (searchlight) is associated with CWE-10 (see above) and operates at 24 kHz.

Van der Heem's 24-kHz searchlight attack sonar is associated with (and shares a dome and mounting with) CWE-10 (see above). Range scales: 1, 2, 3, 4, 6, and 8 km. Pulse width: 0–50 msec (also reported as up to 200 msec). Power: 250 W. Frequency can be varied between 5 and 50 kHz.

This sonar was carried by the Swedish *Halland*- and *Ostergotland*-class destroyers (armed with Bofors ASW mortars), now extinct.

◆ PHS-32

PHS-32 is Signaal (HSA)'s search-and-attack sonar for ships of 200 tons or more. The transducer can be fixed or retractable. PHS-32 can automatically track 4 targets simultaneously (i.e., has 4 pairs of range gates, with automatic video extraction and special software that filters the resulting target positions into an accurate target track for fire control). During sea trials in 1978, in bad weather (sea-state 4, ship rolling up to 25 deg, and pitching up to 10 deg), a submarine was automatically tracked out to 14,000 yd.

The system uses an FFT processor to extract doppler information from echoes in each preformed beam. The B-scan display (bearing-range rather than PPI) is connected to a memory that stores doppler information. Signaal argued that the time-bearing waterfall made detection more likely than a conventional PPI, since the operator did not have to search ever-widening circles. In passive (LISTEN) mode, the sonar can display up to 4 targets in a 20-min time/bearing format. The associated SMR-Mu computer operates the sonar and is accessible via a light pen.

The transducer consists of 30 staves (10 spot transducers each), with 60 preformed beams (effective beamwidth 12 deg, with bearing accuracy of 1 deg; vertical beamwidth is either 12 or 20 deg, switchable during reception). Modes of operation are ODT, TRDT (tribeam), LP (long pulse option), MCC (beam widened in the vertical to maintain close contact), and LISTEN (passive). This system can automatically track up to 4 targets simultaneously. Frequency is 9.3 or 10.5 or 11.7 kHz, with 600-

Hz bandwidth. Pulse lengths are 12.5, 25, 50, 100, and 400 (optional long pulse or FM mode only) msec. Range scales are 1, 2, 4, 8, and 16 kyd; and range accuracy is 0.5–2% of full-scale range (range gate is 1/16 of the range scale). The system can maintain a time/bearing history for 20 min. The transducer's diameter is 730 mm, and total weight of the fixed hull outfit is about 7000 kg. The retractable hull outfit weighs about 2500 kg and can be lowered or retracted at up to 24 kt.

The display includes a ray-path predictor, using a sound-velocity profile from an on-line XBT. PHS-32 incorporates built-in test equipment.

PHS-32 was a private-venture development. It was reportedly the first operational sonar to use advanced digital signal processing (FFT and pulse compression). Design work began in 1974, and hardware contracts were awarded from 1975 on. The first unit was tested in 1977–78.

PHS-32 users: Korea (*Ulsan* class and some *Donghae* class, a total of 25 sets), Indonesia (training frigate *Hajar Dewantara*, *Fatahilah*-class frigates, and the PB 57-class patrol craft *Andau* and *Singla*), and Nigeria (MEKO 360-type frigate *Aradu*).

◆ PHS-36

This LF bow sonar is a derivative of the PHS series and also of the Canadian Westinghouse SQS-509. PHS-36 operates at 5.5, 6.5, and 7.5 kHz (5-kW pulses, 15-deg beam) and in 4 active

modes plus a passive mode. In the new M-class frigates, the sonar transducer is derived from that of the French DUBV 25, with PHS-36 electronics.

PHS-36 began with a Dutch navy requirement issued in the late 1970s. It was a joint venture with the Royal Netherlands Navy and the Dutch National Defence Organization (TNO). Detection, track initiation, and tracking are automatic.

PHS-36 was first tested in 1979–81 and was first installed on board the frigate *Jacob van Heemskerck*. Nine (with the French wet end) were ordered in 1987 for M-class frigates.

◆ SIASS

Signaal's Submarine Integrated Attack-and-Surveillance Sonar System was first fitted to the Taiwanese *Hai Lung* class (the Dutch *Walrus* class uses a Thomson-CSF suite). SIASS-1 has its own consoles and can interface with other systems; SIASS-2 is integral with SEWACO (see tactical-data systems in the Surveillance and Control section). SIASS consists of a cylindrical bow array (96 staves, each with 4 transducers), a 4-element HF acoustic-intercept array, a set of flank ranging arrays, and a cylindrical active transmitting array. Three square passive-ranging arrays (25 hydrophones each, arranged 5×5) are fitted on each flank of the submarine; they provide a total of 64 preformed receiving beams, counting both sides of the submarine. The bow array, with 96 preformed receiving beams, is used for narrow-band and broad-band listening, for LF acoustic intercept, and as the receiver for active operation.

A full flank array, for low-frequency coverage, is available as an option.

The system can store up to 35 tracks, carrying out contact-motion analysis (TMA) on up to 20 of them. The broad-band systems of the cylindrical and flank arrays each provide 4 such channels, on 8 preselected frequencies; there are 16 more for HF and LF acoustic intercept sonars, and 4 more for the active sonar. In at least some cases, tracking is based on the automatic association of inputs from different sensors operating in different frequency ranges. Each sonar has an electronic classification library of up to 300 specific platforms (100 ship classes, 100 sonar types).

The output of each of the 160 receiving channels (beams) is subject to complex FFT analysis for LOFAR, the computer holding 15 min of history on each (total capacity 2 Mbytes). This history can be displayed either as broad-band (time vs. bearing, i.e., waterfall) or narrow-band (frequency vs. bearing, or frequency vs. time for 1 beam, or amplitude vs. frequency integrated over time). Signaal claims that the ability to call up LOFARgrams at will (using the 15-min memory), rather than waiting for them to build up over time, allows their use for target detection rather than merely for target classification or monitoring. There are also enhanced classification channels, Zoom-LOFAR (high-resolution vernier analysis) and DEMON (demodulated noise, enabling the sonars to measure frequencies below 100 Hz by demodulating higher-frequency noise, such as flow noise or cavitation, to get at fundamental frequencies). DEMON allows measurement of blade and shaft rates.

The cylindrical and flank arrays can also be used for multi-target tracking, and different targets can be tracked in narrow- and broad-band at the same time, the broad-band track being by noise over a selected frequency interval, the narrow-band by specific frequency line (for automatic tracking of a crossing target). Active modes are single-ping (directional) and single- or multiple-ping ODT, and the active sonar can automatically track multiple targets.

Normally the passive-ranging sonar is slaved to the main cylindrical array in the bow, so range can be calculated automatically once a broad-band contact enters the ranging sector. The method is measurement of wavefront curvature by frequency-domain correlation, and bandwidth is varied to reject specific noise sources.

The HF intercept sonar operates up to 100 kHz, and uses an FFT processor to detect, classify, and correlate contacts. The

A PHS-36 sonar CRT shows a PPI display (lower part), a range-correlation display (upper green part), a track table (top), and light pen-operated controls (right). The operator selects the closely related pictures needed for the specific task: e.g., sonar tracks and surface-search radar tracks can be combined on 1 display. The processor conducts FM and CW processing simultaneously to cope with both noise-limited and reverberation-limited conditions. The main sonar-processor functions are auto-detection, auto-track initiation, and auto-track processing. The operator does not form part of the detection chain. This CRT is part of a General Operator Station (GOS) console, which also has access to the ship's tactical data-handling system (the Sewaco VII CDS of an M-class frigate). (Signaal)

intercept sonar incorporates a threat library and can warn automatically of, e.g., torpedoes.

Work on the system began in the early 1980s, to provide a new system for export submarines. The first production models were completed in 1982/83, the first installation being on board the submarine *Walrus* in 1985. SIASS is also installed in the 2 submarines built in the Netherlands for Taiwan. The associated combat system is Spectrum.

UNDERWATER FIRE-CONTROL SYSTEMS

◆ M5

Signaal's surface-ship ASW FCS, designed to work with a searchlight attack sonar, was broadly analogous to the U.S. Mk 105. M5/1 was a 375-mm FCS for the *Koln* class, working with its M9 torpedo FCS. Initially, M9 used the M5 analog computer. However, by 1966 M5/1 had been modified to use the digital computer of the M9/6 system. Given sonar (range and bearing) and own-ship data, M9 (see below) calculated target course and velocity so that future target coordinates could be generated. The system also kept the searchlight sonar on the submarine target and held the last target range and bearing in the event that contact was lost. M5 also incorporated a ray-path analyzer to use BT data to estimate sonar beam bending. Target course and speed were displayed on a vertical CRT, and target depth was shown on a paper printer.

M5/4 (1961) was a developed digital version controlling both rockets and torpedoes on board *Hamburg*-class destroyers and *Thetis*-class corvettes; it was also used at the German navy's underwater-weapons school. This system ran 3 separate plots: an ASW plot, a surface-target plot, and a summary plot. All fed in turn into a pair of digital computers. The search sonar and search radar fed into both the ASW and the surface-target plots, but the attack sonar and the passive sonar fed into only the ASW plot. The ASW plot controlled depth-charge racks directly, but the torpedoes and ASW rockets (Bofors 375-mm) were controlled by computer (or, in the event of a casualty, directly from the ASW plot). M5/4 used a pair of standard Signaal 4-operator (SEWACO-type) horizontal consoles for its ASW and surface-target plots. The ASW console typically had 4 operators: the ASW officer, the unguided-torpedo/depth-charge operator, the guided-torpedo/rocket operator, and the display operator (across from the ASW officer). The ASW officer could enter data from any of the 3 sonars (attack, search, or passive) or from the ship's radar, could vary the range scale (6/12/24 km), could switch to synthetic video, and could throw out the computations of either of the 2 system computers or the ray estimates based on temperature. The ASW officer could also enter corrections to a running solution. The unguided-weapons operator could preset torpedoes (speed, stratum, horizontal search, lower depth limit, homing), choose tubes, and fire depth charges. Similarly, the guided-weapons operator could choose among torpedo and rocket tubes and among rocket salvos (single, 2-rocket, or 4-rocket) and could control wire-guided torpedoes (search speed, course, depth limits, switch to active homing, fuzing). The display operator controlled 2 cursors in range and bearing. The parallel surface-target display had 3 operators: a targeting (supervising) officer, a wire-guided-torpedo controller, and a display controller. In this case the targeting officer chose among inputs from the search sonar and the 2 main radars, deciding which to enter into computation and which computer solution to accept. The targeting officer could also use the GFCS (M2/2) to control a torpedo. The torpedo operator could choose between 2 types of torpedoes (Nixe or Seal), could choose among 2 tubes, and could control such torpedo functions as search speed, direction, and the shift to active search.

When the *Hamburgs* were rebuilt, M5/4 was modified to control their Exocet missiles. These ships also had an MV2-3 GFCS controlling their 100-mm guns (M2 plus a V3 radar height-finder).

The missing Signaal project numbers (M3, M6, and M7) all refer to abortive projects.

◆ M8 Series

Signaal's (HSA's) submarine-torpedo FCS equips most Type 209 submarines. The most common version, M8/24, can simultaneously track 3 targets, prepare fire-control solutions for 3 targets, and control 3 torpedoes. The maximum own-ship speed is 40 kt, and the maximum target speed is 60 kt. M8 can control straight-running, homing/programmed, or wire-guided torpedoes.

The initial version, M8/0 (1955), used an analog computer, but M8/1 (1960), designed for the German navy, introduced a special-purpose, solid-state, digital computer. Tactical data were displayed on a PPI instead of on dials; M8/1 was an early example of the integration of AIO and FCS. Because the computer was programmable, it could be used not only to calculate torpedo lead angles but also to process all sensor data to give target positions and vectors; it could simultaneously display sonar, radar, and periscope range and heading data. Programs were developed to compute positions (either active or passive), to evaluate periscope-bearing data (with estimates of range, heading, and course), and to evaluate passive bearings (TMA, based on a stereotyped own-ship maneuver).

All versions of M8 are centralized, a command and weapons-control console being fed by all the sensors (some of which have their own dedicated operator consoles). The addition of special-purpose computers has generally increased the capabilities of M8, and these computers have ultimately added an automated plotting capability for TMA (i.e., well beyond what was needed for torpedo FCS).

Range scales on the main PPI are 5/10/20 km or 5/10/20/40 kyd. The system incorporates a ray-path analyzer, and there are local controls and gyro-setting panels in the torpedo room. The PPI can show true motion, relative motion, or off-centered motion.

Versions:

M8/0: for the Dutch *Dolfijn* class, replaced by M8/17.

M8/1: for the German Type 205 class (1960, introduced the digital computer).

M8/7: for the *Zwaardvis* class.

M8/8: for the German Type 206 class.

M8/10: for the Norwegian *Kobben* class (Type 207), replaced by MSI-70U.

M8/12: for wire-guided-torpedo tests, for the German navy (MK 37-0, Seeschlange, Seal), 1964.

M8/17: for the *Potvis* class (replaced M8/0).

M8/18: for the German *Wilhelm Bauer*, a test submarine.

M8/19: for the Greek Type 209 submarines (the first Type 209s).

M8/24: for export Type 209 submarines. M8/24 may be in the Danish *Narhvalen* class. It was the last of the series; SINBADS is the successor.

M8/41: a new system with a general-purpose digital computer, renamed SINBADS (see below).

◆ M9 Series

The M9 designation applies to 2 quite different digital systems. M9 was originally a surface-ship torpedo FCS for the German *Koln* and *Thetis* classes, working with a searchlight sonar. Later, however, the same designation was applied to a stand-alone ASW FCS that worked with a scanning sonar (such as PHS 32), primarily to control the Bofors 375-mm ASW mortar.

The original M9/1 (1958) controlled fixed above-water tubes firing unguided torpedoes, using the associated M5/1 system to generate target location and course. Other data such as the observed position of a submarine's periscope, could also be used. The maximum computed target range was 3600 m. M9/3 was the digital version (1961) actually used on board the *Koln* and *Thetis* classes.

The later M9 uses a standard Signaal horizontal 3-operator console and separate computer/interface cabinet (containing an SMR-S computer) without PPI. It collects, correlates, processes, and stores target data, solving the ASW fire-control problem. In

this version M9 is primarily a mortar-control system, but it can also control Mk 32 torpedo tubes via a Mk 264 Mod 1 control panel. Reportedly, M9 is related to the M11 fast-attack-boat system, described below.

No installations have been announced, but likely ones are Indonesia (the frigate *Hajar Dewantara* and the *Fatahilah* class and possibly the 2 fast ASW attack craft), Malaysia (the FS 1500-class frigates), Nigeria (the *Aradu*), and Spain (the *Descubierta* class, also in Egypt and Morocco). The Indonesian *Hajar Dewantara* and the fast attack craft are unique in this group because they carry SUT dual-purpose wire-guided torpedoes, which are fired from tubes facing aft. Other ships carry Mk 32 tubes.

◆ M11

Signaal's surface-ship torpedo FCS is used to engage surface targets. It is in the Argentine *Intrepida*-class (TNC 45-type) boats and probably in the extinct German *Zobel* (modernized S142) class. These boats all have or had stabilized Signaal radars in "eggs." The data below refer to the simplified VM11/2 version, which was designed about 1966 to work with unstabilized sensors (optics, ESM, and radar), controlling Seal wire-guided torpedoes. VM11 is presumably the element of the Vega systems (such as that on board Greek *Combattante-II* and *-III* attack boats) that controls German-supplied wire-guided torpedoes (Vega PCET presets the torpedoes but is unlikely to control them after firing). VM11/2 uses a special-purpose digital computer to calculate target course and speed from a series of radar observations. The system can also operate on purely passive data (computing a collision-course attack). The maximum range is 30 kyd (the maximum firing range is 20 kyd); the minimum range is 300 yd, and the maximum torpedo course change is 14 deg/sec (the maximum boat course change is 8 deg/sec). The maximum target/own-ship speed is 50 kt. On the plotter, 1 mm = 600 m. The system can compensate for the rolling of the firing boat within 30 deg (at up to 25 deg/sec) and its pitching within 10 deg (at 15 deg/sec).

◆ SINBADS

Signaal's Submarine Integrated Battle and Data System can track automatically after a firm contact has been established, based either on continuous bearing data or on range and bearing supplied intermittently by an active sonar. There is also a semi-automatic mode allowing comparison of information from various sources; this mode is capable of detecting target maneuvers and of determining the target's new parameters after a maneuver. Target evaluation is based on a target-motion-analysis display.

Like other combat systems of its time (the 1960s), SINBADS is built around a central computer, in this case an SMR-S optimized to process track data by Kalman filtering. The single operator can call up any 1 of 3 displays: a track display for target evaluation; a PPI for weapons control; and an alphanumeric display showing selected data. Alternatively, raw data from any particular sensor can be called up. The console is the standard Signaal tactical and weapons-control console used in the WM20 series (M8 uses the M20-series console, with its smaller CRT). There is a separate passive-sonar console attached to the main console. The latter carries a 16-in CRT operating as either a PPI (for active sonar or radar) or a time-bearing (waterfall, for passive sonar or ESM) display. The main console also carries a 7-in rectangular graphics display showing bearings-only data, a 7-in rectangular display of alphanumerics, and an optional 15-in tote (alphanumeric) display on top. Options include a computer-controlled Contact Evaluation Plot. SINBADS handles digital and analog torpedoes (including wire-guided ones) for up to 8 tubes. The system must be connected to amplifiers to preset analog torpedoes.

Weapons-control functions are (i) weapon assignment/torpedo setting; (ii) prediction for aiming; (iii) firing preparation; (iv) torpedo wire-guidance/monitoring. Up to 3 torpedoes can be assigned simultaneously, and SINBADS can track up to 5 targets

simultaneously and engage 3 of them. Prediction includes continuous calculation of a torpedo's course (from assignment to end of run for guided torpedoes, or until firing for nonguided ones). The system automatically tests torpedoes before firing them.

Over 20 systems were exported between 1975 and 1985. Users are Argentina (TR 1700 class), Greece (later Type 209s), Indonesia (Type 209s), Peru (later Type 209s, now being replaced by SEPA Mk 3), and Turkey (later Type 209s). SINBADS may have replaced M8/24 on board the Ecuadorian Type 209s.

◆ GIPSY

GIPSY was designed specifically for the *Walrus* class. Unlike SINBADS, GIPSY provides a separate Signaal SMR-MU computer for each of 7 interchangeable consoles. In addition, there are 2 SMR-MU computers for system management (1 on standby), and 2 SMR-MU computers for sonar-data handling. A 16-in PPI presents sonar or radar video. Contacts can be displayed in time-bearing (waterfall) form, and their movements computed by TMA.

◆ SEWACO

SEWACO is a new-generation system for submarines down to 800 tons. First installed on board the Taiwanese (GOC) *Sea-dragon* class, SEWACO developed into Spectrum.

◆ Spectrum

This combat system, developed from SEWACO for the 2 Dutch-built Taiwanese submarines, integrates the full spectrum of combat system functions, including sensor operation. Spectrum is normally associated with the SIASS integrated sonar (see above). The system is digital and software-based and provides high-resolution spectral analysis in each preformed beam to improve the probability of detection and to assist in classification. Memory suffices to store the results of this analysis (LOFAR-grams) for later display.

Spectrum is built around a data bus feeding 3 or 4 multifunction consoles. Sensor data are preprocessed before being fed into the data bus, to reduce the load on the consoles. The active transducer and cylindrical receiving array feed into a common processor (with separate preprocessors for active and passive operation); the passive ranger and acoustic-intercept arrays share a common processor (with separate front-end preprocessors); and the nonacoustic sensors (ESM, radar, periscope, and navigational aids) share a common processor. Each console is a SIGHT general-purpose workstation with a 19-in color screen and a smaller alphanumeric display. Input is by keyboard and a rolling ball, and each console contains 2 SMR-MU general-purpose computers. Besides sonar functions, the system carries out analysis of periscope data, maintains a plot, associates multiple tracks to reject false alarms, assists in navigation, and simulates sensor inputs for training. Two identical weapon-electronics cabinets each contain interfaces to control half the torpedo tubes (normally 4 each).

Spectrum can maintain 35 simultaneous tracks, and it can control 4 missiles (such as Harpoon) and 4 wire-guided torpedoes simultaneously. The classification library holds up to 300 signatures.

Spectrum II is being developed, using the standard processing and display components of the new *Karel Doorman*-class frigates. The display units have 1376 × 1024-pixel color raster screens and employ 68020-series microprocessors. They are connected by Ethernet data buses (10 Mbytes/sec), and data are recorded on 2 digital optical disks with a capacity of up to 250 Mbits each.

NORWAY

SONARS

The only manufacturer is Simrad, which entered the military market after producing fish-finding and whaling sonars. The company announced details of 4 main types in 1975-76: SU,

ST, SQ-D, and SK3-D, the largest being the SU-RS searchlight. Later the company announced the SS series.

The current sonars, in descending size order, are SU, ST, SQ4, SB2, SK3, and SL. Details are given only for those sonars known to be in current service.

◆ SQ Series

The SQ series operates at 27 kHz (SQ-D operates at 24 kHz and uses a fixed streamlined dome). Standard instrumented range is 2500 m (peak power 4 kW, which can be increased to 8 kW), and the beam is 12×16 deg.

The Simrad SQ3-D/SF is in the Swedish *Hugin* class and the minelayer/training ship *Carlskrona* and in the Finnish navy. SQ3-D/SF operates at 24 kHz (4-kW peak power) and has 5 range scales (maximum 2500 m). It can search automatically, the array training through 360 deg in bearing and through 90 deg in elevation. The usual sonar speed of a *Hugin* is 22 kt.

SQ-D is similar, but the transducer is retractable in a fixed rather than a retractable dome. SQ3-D is on board Norwegian *Vidar*-class minelayers.

◆ Simrad SS105

This scanning sonar for the Norwegian coast guard (*Nordkapp* class) provides range and bearing data to the Kongsberg NAVKIS combat-control system. The transducer consists of 48 staves and has 48 preformed receiving beams (each 10 deg wide), using split-beam processing in each beam. Frequency is 14 kHz, and total output power is 15 kW. Transmission modes are ODT and tribeam, and the range scales are 2–16 km. LEDs are used to indicate the target's range and relative/true bearing and own-ship's speed, and there is an 11-in CRT (PPI). The dome can be fixed or retractable, and the sonar can be used at speeds of up to 25 kt. Retraction, when it is provided, is by an unusual pivoting mechanism.

SS105 is also on board Finnish *Turva* and *Kiisla*-class coast guard ships.

◆ Simrad SS240 Series/ST240

This sonar for small patrol boats, developed from SS304, was announced in 1986. SS240 is an active scanning sonar using preformed beams, with ODT, sector, and RDT modes. Both transmission and reception beams may be tilted from +10 to -20 deg, and there is also an MCC mode with a broad vertical beam in both transmission and reception. The transducer is cylindrical (diameter 42 cm, weight 300 kg). Operation is at 24 kHz (7-kW pulses, pulse length 2–160 msec, both FM and CW). Instrumented ranges are 200–6000 m in 200-m steps. The PPI display shows echoes in 8 colors to indicate various signal strengths. Target data, including range, bearing, course, and speed, are displayed in green; and the operator can select true or relative motion.

SS242 is the fixed-transducer version.

ST240 is a lightweight 24-kHz towed sonar derived from SS 240. It can operate either as a VDS (towed at speeds of up to 12 kt) or as a dipping sonar. Four were ordered for Finnish *Helsinki II*-class fast attack boats, and at least 13 were ordered for the Royal Swedish Navy.

◆ SS 304 (Spira)

This searchlight sonar (operating at 34 kHz) was designed for small fast craft (down to 150 tons, up to 40 kt). The 17 preformed receiving beams cover an 85-deg sector with a single ping, and the transducer can be turned and tilted (limits +15 to -105 deg) to cover the full 360 deg. The beams are narrow in the vertical, for shallow water. The display uses 6 colors to provide a true-motion picture of the underwater situation. Maximum instrumented range is 4000 m. This sonar is used on board Swedish *Göteborg* class and *Stockholm*, in combination with the French-supplied *Salmon*, and on board the Finnish *Hel-sinki* and *Turunmaa* classes.

This sonar was developed from the SM600 fish-finder, which

was demonstrated to the Norwegian navy in December 1982 on board a fishing boat.

◆ SU Series

This series is frigate searchlight sonars. SU-RS, the Stabilized Survey Sonar, has a retractable dome and can operate at over 20 kt. SU-RS trains through 360 deg and can tilt +20 to -110 deg. It is azimuth stabilized and also stabilized against pitch and roll. SU-RS operates on 1 of 4 working frequencies (12, 14.5, 18, or 24 kHz) with range information given on a moist- or dry-paper recorder. At 18 kHz the transducer (total radiating area 1600 cm²) produces a 10.5×12 -deg beam. Peak power is 4 kW (8 kW optional, with a second transmitter). Maximum instrumented range (with a scale divided into 6 ranges) can be chosen between 3500 and 9000 m, and there is also an audio channel for watch-keeping. The sonar's center frequency is set to 1 side of the receiving filter band, leaving more room for positive (approaching) than for negative (retiring) doppler. There is also an optional PPI, which can pulse the sonar at very short range (75 or 150 m), out to a maximum of 500 m, for high-resolution survey work.

SU-R is identical but lacks stabilization in pitch and roll.

SU is used in Irish *Deirdre*-type OPVs, in the British *Hecla*-class survey ships, and in Malaysian *Spica-M* fast attack craft.

◆ Terne Attack Sonar

This stabilized searchlight tracking sonar has a maximum instrumented range of 3000 yd and a depression angle of 35 deg (with a maximum instrumented depth of 1000 ft). The minimum depression angle is 5 deg. The range scales are 1000 and 2500 yd. The sonar incorporates a horizontal-range and depth computer. This sonar can be controlled by a scanning sonar, which triggers it in range and controls it in bearing. For example, as tested by the U.S. Navy in the early 1960s, the Norwegian attack sonar, designated SQA-16 (depth determining group), was controlled by an SQS-31 or -32.

UNDERWATER FIRE-CONTROL SYSTEMS

◆ MSI-70U

Kongsberg's Multi-Sensor Interface for the *Kobben*-class submarines, MSI-70U was 1 of the first systems to employ Kalman filtering to assist in associating data from different sensors to form a fire-control solution. The associated computer is SM-3. Units being modernized are being fitted with the new MSI-90U and the Thorn-EMI D3 data-distribution system built around a 1553B bus.

◆ MSI-90U

Development of Kongsberg's automated submarine command/control system began in 1980, for new Norwegian and German submarines (*Ula* class and Type 211). The initial study was completed in 1982, and a Norwegian-German MoU signed in December 1982. The prototype multifunction display was completed in mid-1983. MSI-90U will form a common-core (federated) combat system, with each partner supplying its own sensors, and will communicate with the consoles via a new BUDOS data bus. The computer is KS900F. Because both navies expect to operate in target-rich environments, MSI-90U is designed to support multiple engagements in quick succession. It can track 12 targets simultaneously and can handle 8 weapons.

A full system consists of 4 multifunction operator consoles (each with its own computer), a computer rack (with 3 main computers), and a weapons-control unit (WCU) (with 2–3 weapons computers), all tied together by a BUDOS data bus (as in the NFT surface-ship systems). All of the computers are KS900s, and the BUDOS bus is provided with 3 multiplex terminals (MUX), each of which can connect with up to 8 users. BUDOS itself can accommodate up to 15 MUXes, far beyond the needs of the system. Each of the single-operator consoles has 2 high-resolution, color, raster-scan screens; the operator enters data

via a programmable plasma touch screen, a trackball, and a standard keyboard.

The console display shows:

- Situation and Interaction Plot (SIP), the overall tactical situation
- 4 Workplots, which can be viewed in sequence: TMA, Torpedo, Tactical, and Auxiliary

The display can show a digitized radar picture; radar data can be used for target range and bearing. Presumably, the system can easily accommodate a future optronic periscope since its raster-scanned screen has sufficient flexibility and resolution.

One console (the central command unit) is fed by the digital scan converter for the submarine's radar. It is near the steering console and the plotting table on the starboard side of the boat. The other (identical) consoles are arranged in a line on the port side, next to the sonar consoles.

The system as a whole can conduct simultaneous automatic and operator-interactive TMA on up to about 30 targets, can guide several torpedoes (the number depends on the design of the submarine) simultaneously, and can prepare and lay up to about 50 mines (registering positions, while also keeping track of up to 15 hostile mines being laid). Missile preparation and firing (1 missile at a time) is an option. Torpedo-guidance modes are line of sight, collision course, and manual.

The system carries classification data bases for radar, sonar, and platform identification, both for IFF and to plan engagements. It also conducts geographical/oceanographic modeling, forming contour maps and predicting sonar performance. Sonar ranges are used for TMA, for threat evaluation, and for weapons control. MSI-90U provides threat evaluation as well as engagement analysis. The latter function shows whether a target is within torpedo range, computes firing positions (estimating hit probability), and automatically optimizes firing parameters.

Factory tests began in 1986, and the first unit, for the Norwegian submarine *Ula*, was delivered in April 1988.

SOUTH AFRICA

The International Maritime Technology (IMT) company of Simonstown has developed a towed array, intended as a technology demonstrator. It was used in 1988 to find the flight-deck voice and data recorder from the South African Airways 747 that crashed in the Indian Ocean. This device might form the basis of a future South African navy sensor. Although no surface ASW ships are currently in service (no likely enemy in southern Africa has submarines), there has been a proposal to build a new light frigate to replace the Minister (Israeli *Reshef*)-class fast attack boats. The array might also be installed on board the South African submarines, the combat systems of which have reportedly been replaced with indigenous equipment.

SWEDEN

SONARS

◆ Bottle Cap

A joint SAAB-Simrad VHF sonar, for harbor defense, hull mounting, or helicopter dipping, Bottle Cap was announced in 1987. Bottle Cap's square-plane receiving transducer is trainable, and the beam is scanned electronically across the transducer in both elevation and azimuth. The projector is a line array below the receiver. Targets are detected automatically, out to a range of 1000 m, and several can be tracked simultaneously. The transducer can be tilted, and the sonar incorporates a compass. Bottle Cap can be bottom-mounted or used as a dipper. Pulse length is 0.1–10 msec, and the horizontal beamwidth is 1.9 deg. Vertical beamwidth is adjustable (6, 12, 18, or 36 deg), and angular resolution is 0.225 deg (mechanical step size is also 0.225 deg). Scan rate is 15 deg/sec at 200-m range (range scales are 0–5, 10, 20, 50, 100, 200, 500, and 1000 m). For automatic target designation at a range of 500 m, resolutions are about 1

deg, 2 m, and 1 kt. In the zoom mode at 500 m, resolution is about 1 m. In a typical application, the sonar might scan over a 275-deg arc using a 1000-m range scale, scanning every 20 sec. Display resolution is 512 × 512 pixels (128 colors). The scan pattern can shift range scale every 7.2 deg, providing 50 different ranges over 360 deg, and 100 such patterns can be stored. The range changes are necessary to allow for the irregular contours of a harbor bottom. The very high frequency was apparently chosen in hopes of detecting small submarines.

As of November 1990, Saab Instruments was working on a new short-range scanning system using a blue-green laser to complement or replace Bottle Cap. This underwater radar was the subject of preliminary discussions with the Swedish Defense Administration and with the Swedish military research-and-development community. At that time Saab expected to begin marketing its underwater radar in about 6 months, i.e., about May 1991. The announced Bottle Cap range, about 1000 m, would not be very far from known underwater laser performance. The Saab device would seem to be the first underwater laser radar to have been made public.

◆ 9SA100

This BEAB HF surveillance sonar was announced in 1990. It is intended for use in an upward-looking acoustic fence, as a controlled mine field sensor, or, looking down, for ship security against swimmers. 9SA100 can also be used as the active element of a mine sensor, turned on only when passive sensors on the mine detect a likely target. Presumably, it is part of current Swedish work on a rising mine. The only published brochure suggests that 9SA100 produces a relatively narrow beam and distinguishes targets only by their range (in a test, it detected 2 frogmen swimming close together).

FIRE-CONTROL SYSTEMS

◆ AI-FCS

AI-FCS is Datasub Communications's Action Information–Fire-Control System for A 17-class submarines. It uses 2 identical consoles, each of which can show any of 4 plots: contact-evaluation plot (CEP), operational plot (OP), tactical plot (TP), and fire-control plot (FCP). CEP is used mainly when TMA would be unsuitable, e.g., when a contact can be detected only sporadically, or at very long range. Collected information is shown in time-bearing (waterfall) form, covering all 360 deg and up to 2 hr vertically. The OP (in effect, a navigational plot) is used during transit to the patrol area. OP shows features such as own and enemy mine fields, mission information, coastal radars (with their parameters), the route, and the operational area itself. The OP can show 50 internally generated points, 10 target channels for TMA, up to 240 plots received externally by data link, and 32 ESM emitters or emitter modes. Normally the TP is used for TMA, while the submarine is preparing to attack; up to 10 targets can be analyzed simultaneously. In the TP, own-ship is at the center, and there are no navigational displays, although 8 reference points can be used to show, e.g., the boundaries of the patrol area. Up to 50 internally generated plots can be shown, and also a list of which sensor is tracking which target. For longer ranges, the OP is better because it shows chart information and true motion. Finally, the FCP is optimized for rapid automatic multiple engagements, controlling up to 12 torpedoes simultaneously. It normally shows relative motion (own-ship at center), but it can be centered on a torpedo. Typically 1 console is used as command station (showing CEP or OP or TP), and 1 is fire-control station.

The computer's storage capacity is 512k (32-bit words), with a storage cycle time of 750 nanosec (clock speed 1.3 MHz) and an average execution time of 2.5 microsec.

A reduced form of this system has been installed in Swedish *Sjoormen*-class submarines during their mid-life refits.

◆ NEDPS

Nacken Electronic Data Processing System, manufactured by Datasaab, is the computer-driven combat system of the Swedish *Nacken*-class submarines. Requirements were formulated in 1966–67; they included passive fire control (by TMA, which the Swedes call target-factor calculation, or TFC) on several targets simultaneously. That capability clearly required a computer. The same computer could also be used for other ship-board tasks, such as machinery control and depth-keeping, and the system evolved from weapons and sensor control to overall submarine control. A simulator, ordered in 1970, was used in 1971–74 to test and develop the requisite software. The system is built around 2 Censor 932 64-kbyte computers, feeding a pair of consoles with CRTs: a tactical plot (TP) and a fire-control plot (FCP). Between them is mounted a torpedo status board (the torpedo fire-control display, or FCD), and there is also an alphanumeric display, the general communication unit (GCU), manned by the ship's electronics officer. The consoles are equipped with keyboards and trackballs. Calculated target tracks are displayed on the TP, which replaces the conventional paper plot; it can also display the signal-to-noise ratios of various targets being tracked. The system can carry up to 50 targets, and it can automatically provide simultaneous TMA (for fire control) for up to 10 of them. Up to 12 torpedoes can be controlled simultaneously.

The Mk 2 version, for the *Vastergotland* and *Sjoormen* classes, uses 1 multifunction console with 2 side-by-side CRTs. The weapons-data boards are above the CRTs. These 3 boards also include alphanumeric displays, e.g., of data links. The system can carry up to 50 labeled targets, with 10 target channels for TMA, 240 external targets (via data link) with target numbers and identifiers, and 32 ESM lines. Ericsson has advertised NEDPS for Type 205 and Type 206 submarine upgrades.

◆ TORCI

PEAB's torpedo FCS for surface ships and fast attack craft uses a search radar. TORCI can engage 2 targets simultaneously with long-range wire-guided torpedoes. The system consists of a control panel incorporating a PPI display, a tracker, and a computer. The main system sensor, a surface-search radar, feeds both the tracker (which has a B-scope) and the main display. Alternatively, targets can be designated optically and the torpedo fired along the line of sight, with course corrections as the ship and target move.

The operator can move a bearing line and a range ring about the PPI, using handwheels. When both intersect on the desired target, it is entered into the system by means of a button. The separate tracker projects target position ahead; the projected position appears on the main PPI. The tracker operator maintains track by keeping the target centered on the B-scope, using range- and bearing-correction handwheels. The tracker also takes into account own-ship maneuvers (the system is automatically fed ship's course, ship's speed (through the water, not over the ground), and a vertical reference (presumably, to correct radar errors caused by roll). The computer continually computes the course a torpedo must follow to intercept the target; the torpedo course and the calculated interception course are both shown on the console. The console also shows projected torpedo running range. If the target is within range, torpedoes are fired from the main console.

Torpedo guidance is either automatic or manual. In automatic mode, the computer automatically transmits signals through the torpedo guidance wire. In manual mode, the torpedo is steered to starboard or port by 2 buttons. In either case, the PPI shows the dead-reckoned torpedo course, based on presets and commands sent. The system as a whole can control at least 2 targets, time-sharing its computer and tracker.

The main PPI, a true-motion display, can also be used for tactical plotting.

TORCI appeared in 1959. It was the culmination of a series of Philips torpedo FCSs. One of the first was the TCA electro-

mechanical system for destroyers, delivered in the mid-1950s. There were also a contemporary submarine FCS (TCI 101) and a motor torpedo boat system (RATSI). The latter was the first Philips system to use radar to track and localize the target. RATSI was evaluated in destroyers, leading to the development of TORCI, to control straight and wire-guided torpedoes.

TORCI was a very early example of solid-state electronics (using discrete devices). Its computer was hard-wired; even so, it weighed 205 kg. The display weighed another 165 kg, and the tracker 125 kg; the fourth component, a control panel, weighed another 120 kg, for a total of 755 kg [1664 lb]. Each component was 620 mm [24.4 in] wide, somewhat more massive than the current 19 in standard.

TORCI users: Denmark (*Willemoes* class), Norway (*Snogg* class), and Sweden (*Spica-II* class).

◆ 9TCI210

Philips's submarine torpedo FCS of the early 1960s controlled wire-guided weapons against surface targets and used a single operator. It is related to the series of fast-attack-boat systems that culminated in the 9LV series (see the AAW section). The main system sensors are a frequency-agile X-band radar with 2 magnetrons (1 on standby), the periscope, and the sonars. The single 12-in CRT can display either the radar picture or a bearing line (from the periscope or the passive sonar) or the target location (bearing and range) given by the active sonar. There are 2 target-tracking computers (i.e., tracking channels). Target bearing and/or range data are entered by push-button. The system is designed to accept intermittent target data; measurements of bearing and range can be made independently. The tracker uses time and movement between measurements to compute target speed and course. Once it is tracking, it generates a tell-back tracker symbol on the CRT. If the target is continuously presented, the tracker can operate in TWS mode. The operator can control the tell-back target symbol via a golf ball and transmit its position to the selected target tracker to correct tracker predictions.

During an attack, the CRT shows torpedo position (as a half-circle), with a course and speed vector. After the full torpedo distance is reached, this symbol is fixed, showing the location of the actual torpedo. Two symbols, a square and a circle, represent the tell-back positions of the target trackers, with the vectors representing computed course and speed. The ship's heading line is presented once every antenna scan. Torpedo and fire controls are in the panels above and in front of the CRT.

9TCI210 can present the full tactical situation in PPI form based on long-range radar search; it can designate targets to sonars and to the submarine periscope; it can present target bearing for plotting. The system can control up to 4 wire-guided torpedoes simultaneously. It can also fire up to 4 preset-angle torpedoes (straight or pattern runners).

◆ 9TC301/9TC302

9TC301 is a digital FCS for Swedish ASW helicopters, firing Tp 42 wire-guided torpedoes. A small data-transmission unit aboard the helicopter continuously and automatically transmits target course and speed to another helicopter or ship so that the latter can attack without transmitting. When controlling other platforms, the master helicopter uses its on-board radar to monitor the position of the cooperating units as well as to provide target data against periscopes or surfaced submarines. The Tp 42 torpedo can also be used against surface vessels.

9TC302 is the production version, first delivered in May 1981. Deliveries were completed in 1983. Development began in the mid-1970s. PEAB was awarded a contract for an evaluation system in 1977. It was delivered in 1978, and evaluation was completed about mid-1979.

USSR

The NATO reporting designations listed below were published in 1986, and many are presumably no more than older systems renamed. Because the only list thus far published associates

Sonar code names only with ships or classes, some of the identifications below may be incorrect. No detailed characteristics of modern Soviet sonars have been published. Moreover, this list may well be incomplete. For example, early Whiskey- and Zulu-class submarines probably had wartime-developed HF passive arrays (MARS-12) that seem not to have received postwar code names. The first modern sonars, Feniks and Hercules, appeared only in 1958.

During and immediately after World War II, the Soviets had access to British and U.S. HF searchlight sonars and to German wartime surface-ship and submarine sonars, including the LF arrays that were developed further in Britain and in the United States. Presumably, the parallel development of Pegas and Tamir reflects parallel work along both U.K./U.S. and German lines for surface ships; it is interesting that the Soviet equivalent of the passive array for big submarines (presumably Trout Cheek) apparently took so long to develop.

No code designations for Soviet helicopter dipping sonars have been published. There are probably at least 2 types, an HF unit in Hormones (see Rat Tail) and 1 MF type in, presumably, Helix and Haze (see Foal Tail/Lamb Tail). There is no published indication of whether these dipping units are searchlights or scanning sonars (sector or omnidirectional).

In 1989 the U.S. Director of Naval Intelligence reported that the Soviets had short-range fixed acoustic sensors in the Northern Fleet operating area, and longer-range planar arrays (code-named Cluster Lance) in the Far East, where geography is more favorable to such devices. Presumably, the devices in Northern Fleet waters are, in effect, acoustic fences that indicate that a submarine has actually passed through them. Such fences could be used to cue nearby aircraft or other ASW platforms and could form part of bastion defenses. The sensors would probably use RAP propagation and thus could function even in relatively shallow water. The DNI also stated that the Soviets were testing a towed surveillance array similar in concept to the U.S. SURTASS, and that within a few years they were expected to deploy surveillance platforms equipped with the new array.

For some time the Soviets have been reported experimenting with, and then deploying, towed arrays. This is probably an experimental array on the stern of a Petya-I-class corvette. Note the fish in the well and the control cabin. (U.S. Navy)

None of these systems is likely to be particularly effective. The current argument within the U.S. defense community is that submarines such as Akula can defeat U.S. long-range passive systems such as SOSUS. SOSUS is likely to be more sophisticated than the Soviet systems, and U.S. submarines are quieter than current Soviet types, including even Akula.

◆ Buck Toe

See Pegas below.

◆ Bull Horn

The MF hull sonar of the Modified Kashin and at least some of the *Sovremennyy* class (others have Bull Nose), Bull Horn is also carried on board the first 2 *Kiev*-class carriers to supplement their Moose Jaw sonars. It is presumably a smaller and less effective equivalent to the bow-mounted Bull Nose of the Krivaks, as the Modified Kashins and *Sovremennyy*s are primarily antiship units requiring sonar mainly for self-defense. Bull Horn is associated with 21-in [53 cm] homing torpedoes. It may, therefore, be broadly comparable to the U.S. SQS-56 (controlling 53-cm torpedoes rather than U.S. lightweights). In the case of the first 2 *Kievs*, the big Moose Jaw is presumably associated with the long-range SUW-N-1 nuclear ASW missile. The need for a smaller sonar for self-defense (using the carrier's 53-cm tubes) suggests that Moose Jaw does not normally cover the full area around the ship, that perhaps it is limited to a selected search sector, and that it may be ineffective at close range. The 2 later *Kievs* have no MF sonar; presumably, the later Horse Jaw suffices for both close-in and distant targets.

During a U.S. visit, Soviet officers on board a *Sovremennyy*-class destroyer claimed a range of 5000 m [about 5500 yd] and stated that this sonar was connected to a computer. They also described the system as a means of self-defense.

◆ Bull Nose

This MF bow sonar is associated with SS-N-14 in the Krivak, Kara, and Kresta-II classes, and with ship-launched ASW torpedoes in the Kanin, *Sovremennyy*, and *Slava* classes. Bull Nose is also the sonar installed on board Grisha. Bull Nose is probably broadly comparable to SQS-23. The associated VDS is Mare Tail or Elk Tail. Bull Nose is probably the 7.5-kHz sonar reported in 1960, using a 7500-yd keying interval (corresponding to its expected maximum range). Bull Nose succeeded Wolf Paw (Hercules) and, presumably, was substantially improved before it could be used to direct SS-N-14.

◆ Elk Tail

VDS for the Grisha class, Elk Tail is associated with the Bull Nose hull sonar. The associated ASW weapon is a 533-mm [21-in] homing torpedo or an RBU-6000.

◆ Feniks (Pike Jaw)

Feniks is the standard Soviet diesel-electric attack (searchlight) sonar of the past. Feniks (Phoenix) is apparently the Soviet name. It first appeared in 1956 and was, typically, combined with Tamir-5L on board submarines. Feniks is in a dome atop the bow of a submarine. Early examples showed only a single

A Foxtrot displays Trout Cheek, Feniks, and Fez, and also a row of hydrophones in the sail proper, Fin Teeth, which ONI assumed was a sonar-intercept system. The extended mast is for radio. (U.S. Navy)

dome. In later units, a narrower stalk, Fez, is visible above the main dome.

Feniks is probably the same as Pike Jaw. At least some of the submarines equipped with Pike Jaw have keel sonars; the standard arrangement may well be a pair of transducers, top and keel. The keel sonar is needed to protect the submarine when it runs on the surface. That protection was important for early Soviet missile-firing submarines, which had to fire while surfaced. Moreover, those submarines firing the antiship version of SS-N-3 had to remain on the surface to provide mid-course guidance.

◆ Fez

Fez is the HF system found in a tall narrow dome atop the Feniks domes on Soviet submarines. Fez is almost certainly an underwater telephone.

◆ Foal Tail/Lamb Tail

These Mirka-class VDSs are associated with Bull Horn and Wolf Paw hull sonars and with the Steer Hide sonar. The VDS of Mirka-II-class corvettes is a helicopter dipping sonar rather than a towed body; the connection, if any, with Rat Tail is not clear. It seems likely that the dipping sonar associated with Wolf Paw matches Rat Tail, and that the sonar associated with the MF Bull Horn is a later MF type, presumably carried by the later Helix or Haze helicopters.

Helicopter-type dipping sonar deployed from a Mirka-II-class frigate. (U.S. Naval Institute)

◆ Hercules (Wolf Paw)

This standard Soviet sonar for surface ships and submarines appeared in 1957. It operated at HF and probably introduced scanning technology to Soviet practice; thus, Hercules was presumably roughly comparable to the U.S. QHB or SQS-10 family. Hercules, apparently the Soviet name, survives on board Soviet-supplied Foxtrots (e.g., to Libya). The standard combination of the late 1950s (and on export units) is a Hercules search sonar plus a Feniks attack sonar. Hercules was also used as a sonar for surface ships, e.g., on board Petyas exported to India. The NATO Wolf Paw code name applies only to the surface-ship version.

Soviet Foxtrot-class submarines show a bulbous sonar bow, reportedly containing Hercules. Given the probable dimensions

of this sonar, it seems likely that the bulb contains an active transducer inside a larger-diameter MF passive transducer, like the U.S. BQR-2/BQS-4 combination. Foxtrots generally also have a sonar in their sails, indicated by the series of bright metal windows about halfway up.

Hercules was the standard Soviet hull sonar of the early 1960s, e.g., on board *Kynda*-class missile cruisers (as built) and some *Sverdlovs* (replacing Stag Hoof), and on board Kashin- and earlier class destroyers, replacing Buck Toe. Wolf Paw is the sole sonar on board Poti-class corvettes.

◆ Horse Jaw

Horse Jaw is a large LF bow sonar carried by the last 2 *Kievs* (and therefore probably by the *Tblisi* class), by the *Kirovs*, and by the *Udaloy* class. It is associated with the SS-N-14 missile and with the Horse Tail VDS. In the case of the *Kiev* class, it replaces both Moose Jaw and the MF Bull Horn.

◆ Horse Tail

This LF VDS is associated with the LF Horse Jaw hull sonar. Unlike earlier Soviet VDS fish, this is saucer-shaped. It is carried by the last 2 *Kiev*-class carriers, by the *Kirovs*, and the *Udaloy*s.

◆ Mare Tail

This VDS, the first in Soviet service, is associated with the Moose Jaw hull sonar in the *Moskva* and *Kiev* classes, and with Bull Nose in frigates and destroyers. Mare Tail is an MF type, and it was tested in 1966 on board a Petya-I trials ship. The Soviet name for this system is Vega.

The prototype of the *Moskva*-class VDS, on board a modified Petya-class corvette. (U.S. Navy)

VDS "fish" of a Krivak-class frigate. (U.S. Naval Institute)

◆ Moose Jaw

This enormous LF hull sonar was first installed on board the *Moskva*. Moose Jaw is also on board the *Kiev*. In the *Moskva*, Moose Jaw is probably associated with the FRAS-1 stand-off ASW rocket and, presumably, was intended to achieve convergence-zone capability. In the *Kiev*, Moose Jaw is, presumably, associated with SS-N-14. The successor sonar in the *Kirov* is Horse Jaw. The associated VDS is Mare Tail.

Moose Jaw is retractable (on 1 occasion, *Moskva* entered the shallow harbor at Sevastopol without retracting her sonar and severely damaged it). That, and the use of Bull Horn as a supplementary (probably self-defense) sonar in the *Kiev* class, suggests that this is a sector-scan rather than an all-around sonar. It may, therefore, be a lower-frequency derivative of the British Type 177, details of which would have been obtained by the well-publicized Soviet spy ring at Portsmouth, which operated just when Type 177 was being developed. The timing would have been about right, and the Soviets would probably have found it much easier to concentrate very high power in 1 sector than in an ODT transmission. The official Soviet model of the *Moskva* shows the sort of teardrop-shaped sonar dome that would be associated with a flat-plate transducer rather than with a cylinder of the appropriate size, and the flat plate would be much easier to retract than a full cylinder.

The Soviet name for this sonar is Orion. It was credited (by the Soviets) with a range of 40 km [about 44 kyd].

◆ Pegas (Buck Toe)

The successor to Tamir, Pegas was installed on board Soviet surface combatants from the Riga class up from 1955 onward. This searchlight sonar is probably code-named Buck Toe. In larger ships it was succeeded by the Hercules scanning sonar. Compared to Tamir, Pegas was credited with better bearing accuracy and with a maximum active range of about 5000 yd. Pegas could maintain passive contact on a cavitating submarine out to about 12,000 yd and could determine a target's depth (which was essential for using the new ballistic ASW rocket launchers then coming into service). Maximum listening speed was about 20 kt, and the sonar could automatically pass its data to the approach-and-attack computer.

◆ Perch Gill

This sonar appears mainly on board Whiskey- and Zulu-class submarines, some of which lack Pike Jaw (Feniks). Perch Gill, a higher-frequency searchlight attack sonar, is probably a submarine version of Tamir, the predecessor of Feniks.

◆ Pike Jaw

See Feniks, above.

◆ Rat Tail

A VDS for Petya-class corvettes, Rat Tail is associated with the Wolf Paw HF hull sonar. Rat Tail is a helicopter-type dipping sonar, rather than a towed body, located in a temporary installation amidships. Presumably, the sonar is that of the Hormone helicopter. The relationship with Lamb Tail/Foal Tail is not clear.

The dipping sonar of the Hormone-A helicopter operates at 14–16 kHz, with a maximum range of 4000–6000 yd.

Reportedly, the Soviet designation for the Hormone-type dipping sonar is OKA-2. It can operate passively or actively. An East German article reports maximum ranges of 5500 m in active mode and 18,500 m in passive mode.

An East German account of coastal submarine-hunting tactics by helicopters mentions an average dipping search speed of 17–20 kt, the helicopters making their dips 1.25 or 1.60 of sonar range apart. The article uses an example in which sonar range is 9150 m, so its figures may be misleading. Reportedly, 6 helicopters have 0.5 chance of finding a submarine in 1 hr in a 50 × 50-km area.

A VDS streamed by a modified Petya-I-class corvette. (U.S. Navy)

◆ Sail Plates

Presumably, Sail Plates is the array of small transducers around the sail of Foxtrot and some later classes of Soviet submarines. When first observed, these transducers were identified as torpedo-warning devices (intercept receivers).

◆ Seal Skin

This sonar appears only on board Romeo-class diesel-electric submarines and Echo-I-class nuclear attack submarines (ex-strategic-cruise-missile submarines).

◆ Shark Fin

This sonar array, reportedly MF for torpedo fire control, is found in the sails of many Soviet nuclear submarines. Typically, Shark Fin is combined with Shark Teeth, although in Echo-II Shark Fin is combined instead with Pike Jaw, Trout Cheek, and Perch Gill. Tango, which is a contemporary of this generation of nuclear submarines, is also equipped with Shark Fin/Shark Teeth.

Shark Fin first appeared on board Echo-II- and Charlie-class missile submarines. Presumably, it is required to control long-range antiship weapons, such as nuclear torpedoes and the SS-N-7 missiles of the Charlie.

◆ Shark Gill

This nuclear-submarine sonar suite was introduced in 1978 on board Victor-III-class submarines and used in later types: Delta IV, Typhoon, Oscar, Sierra, and Akula. It includes a towed array, the pod for which is visible atop the tail fins of the Victor-III, Sierra, and Akula (presumably, it is paid out from the small pipe visible at the top of the Oscar fin).

◆ Shark Teeth

This LF sonar bow array is found in many Soviet nuclear submarines. Compared to Trout Cheek, Shark Teeth is much more completely faired into the curving bow of the submarine. In a November-class nuclear submarine, Shark Teeth is combined with Sail Plate and Pike Jaw, both of the latter presumably faired into the sail. This system is probably associated with the much longer attack range provided by the first Soviet nuclear torpedoes, which, presumably, were designed in tandem with the November class. The submarines had sufficient speed to get into position to attack U.S. aircraft carriers, and the torpedo had sufficient lethal radius to make such attacks profitable even without very precise targeting data. Presumably, November was equipped with a shorter-range attack sonar, Pike Jaw, so that the submarine could also use short-range straight- or pattern-

running antiship torpedoes. Pike Jaw, in turn, lacked the range to control the much longer range antiship homing torpedoes of the 1960s; hence the advent of Shark Fin.

The standard Soviet submarine sonar suite of the 1970s included Shark Teeth and Shark Fin.

◆ Squid Arm

This Alfa-class sonar suite (including also the Mouse Roar sonar) was introduced in 1970.

◆ Steer Hide

This VDS is found in the *Kiev*, *Kashin-II*, *Sovremennyy*, and at least 1 *Mirka*-class corvette.

◆ Tamir (Stag Hoof and Stag Ear)

This Soviet sonar was a copy of British wartime searchlight sets. It operated at 24 kHz. Tamir-5N (Stag Hoof) was introduced in 1947-48 and appeared on board large surface ships up through the *Sverdlovs*. Tamir-5L, for submarines, was introduced in 1950, followed by Tamir-11 and -11M (Stag Ear) in 1952. Tamir-5N was the sonar originally carried by *Skoryy*-class destroyers. In many cases it was replaced by an improved searchlight, Pegas. Stag Ear remains in service on board many smaller combatants, such as minesweepers.

◆ Trout Cheek

This sonar is presumably the large passive array in the bows of Soviet diesel submarines from the Foxtrots on. The prototype was tested on board a pair of Whiskey-class submarines about 1958. Trout Cheek probably corresponds very broadly to the U.S. BQR-2, i.e., by reflecting the use of German wartime LF array technology. When this array first appeared, the U.S. interpretation was that the Soviets had adopted the U.S. SSK (anti-submarine submarine) mission, for which the U.S. Navy had adopted BQR-2 in the first place.

The standard Soviet submarine sonar suite of the 1960s consisted of Trout Cheek and Pike Jaw.

◆ Victor Sonar (No Code Name Known)

Soviet Victor-class submarines have a large chin sonar, first revealed publicly when a Victor-I suffered severe bow damage in a collision in the Straits of Gibraltar. Presumably, this sonar is associated with the SS-N-15 weapon, just as the big U.S. spherical bow sonar, BQS-6, is associated with SUBROC. Presumably, too, the Soviets obtained at least some details of the U.S. sonar

when the Soviets obtained details of the SUBROC system (from which they developed SS-N-15). In contrast to the U.S. system, the Soviet sonar cannot easily exploit sonar propagation paths above the submarine, e.g., the bounce path off the surface. That limitation may mean that the Soviets do not expect to fire SS-N-15 at any great depth, i.e., at any depth at which such paths would be worthwhile.

The photograph of the damaged Victor-I clearly shows a horizontal row of transducers extending across the front of the sonar, suggesting a cylindrical configuration. However, at least one account refers to a sonar sphere in this class. This account would square with the photograph if the (presumably cylindrical) row of transducers were wrapped around the sphere. In that case the sphere would probably function as an analog beam-former. The most likely technology would be that of the Luneberg lens, a microwave device that forms a directional beam from an input at a particular point on 1 side. The corresponding signals measured at points on the other side of the lens have the appropriate phases applied to them. This type of technology is used in the U.S. SLQ-32 ESM/ECM system. In a sonar application, acoustic signals would be used to modulate microwaves applied to appropriate points on the side of the lens pointed toward the submarine, and the microwave signals would pass through the lens. The lens would apply the appropriate phases. On the external side of the lens, the microwave signals would be used to drive acoustic transducers (the microwave frequency would be stripped off). As a receiver, the lens/transducer combination would operate in reverse, microwaves modulating the received acoustic signals so that they could be focused onto the appropriate points on the inner surface of the lens. The advantage of the lens (or of any other similar analog beam-former) is that it avoids considerable computation, which otherwise would be required before signals in any beam could be analyzed. On the other hand, it is limited in the number and composition of the beams it can handle and so has not been used in modern Western sonars.

◆ Wolf Paw

See Hercules above.

UNITED KINGDOM

SONARS

◆ Type 162 and 162M

"Cockchafer" bottom-profile sonars detect bottomed submarines. Type 162 sweeps a narrow beam across the seabed and detects the shadow of an object. Three quartz-strip transducers, each producing a fan beam, are mounted horizontally, flush with the hull near the bow: 1 on the keel and 1 on either side, tilted down at a 25-deg angle. The shadow is shown on a conventional chemical range recorder. Frequency is 50 kHz. Range scales are 300 and 600 yd (Type 162M has a third, 1200-yd scale). The 3 fan beams are about 3×40 deg, and range accuracy is better than 2%.

Cockchafer entered service in 1948. In 1951 it successfully located the wreck of the submarine *Affray*. Type 162 remains in British (and foreign) service and is currently manufactured by Kelvin-Hughes and by A B Precision (Poole) Ltd.

SQS-501 is the Canadian version of this sonar.

◆ Type 164B/Type 174/Type 176

Type 164, a modernized version of the wartime Type 144, was the first postwar British production sonar (Type 144 was the first sonar to be based on wartime experience). The main improvements were the following: a transmitter using a master oscillator tube; a ship's component mechanism that corrected sonar readings for ship's motion across the target track (and thus could pass the correct bearing to a Squid mortar); a modified bearing recorder (which eliminated ambiguities in the earlier type); and a sonar repeater for the helmsman. These were improvements in wartime practice. However, as described below under Type 170, the great postwar problem was that submarines

This Victor-class submarine collided with a merchant ship near the Straits of Gibraltar in October 1985. Under emergency repair, she shows the upper line of transducers of her chin sonar (just at the waterline), as well as her characteristic torpedo tube arrangement: 2 above, 4 below. (U.S. Navy)

might be so fast that they could elude searchlight sonars altogether. The interim solution, first tried in the experimental Type 160X (on board HMS *Scorpion*), was to add a second (search) transducer, forward of the main attack transducer and separately trainable because it was mounted on a second shaft. Typically, the second sonar was limited to a range recorder because it was intended to search rather than to track. This second sonar was designated Type 174; it was a second Type 164 transducer, but it lacked the HF (38.5-kHz) Q2 strip used to maintain contact at steep angles and at short ranges specifically for attack. Type 174 was retained when Type 164 was superseded by the much more powerful Type 170 attack sonar. Ultimately, Type 174 was superseded by true search sonars, Types 177 and then 184.

Types 144, 164, and 174 all operate at 14–22 kHz, with range scales of 1.5 kyd (for attack) and 3 kyd (for search). The depth-determination limit (using the Q strip) is 1500 ft (Type 164). The Q strip produces a beam 3 deg wide, extending down to a depression angle of 60 deg. The main beam is about 10×10 deg.

Type 164 entered service in 1950. It was the standard British destroyer sonar of the 1950s, and it was widely exported. It survives on board the Chilean *Almirante Williams*-class destroyers and the Ghanaian Mk 1 corvettes. Presumably, each carries a secondary Type 174 transducer.

Type 174 survives (in combination with Type 170) on board the Bangladeshi frigate *Umar Farooq* and possibly on board the Pakistani ex-missile destroyer *Babur* (see below). In other cases, Type 174 was replaced by PMS 26.

Type 174 was used as a large-ship self-protection sonar in combination with a passive-torpedo-detection set, Type 176 (now probably extinct). Type 176 operated at 20 kHz; an 18-kt ship carrying it could detect a 45-kt steam torpedo at 2500 yd (a 24-kt ship could detect the torpedo at 1500 yd, and a 30-kt ship at 500). Type 176 had a single-operator display, typically in the Operations Room (CIC). These sets survive, if at all, on board the Argentine carrier *25 de Mayo* and the Indian *Vikrant*. Because it provided omnidirectional listening, Type 184 replaced not only long-range search sets but also the large-ship defensive sets. The sonar sometimes listed as Type 174 for the Pakistani ex-missile destroyer *Babur* is probably Type 176, working in this case in combination with Type 177.

◆ Type 170B

This set was the "4 square" attack sonar associated with the Limbo mortar. The transducer was square, arranged as a diamond, the 4 beams being compared to keep the sonar pointing at the target both in bearing and in elevation. Type 170 was conceived as part of an automated underwater FCS, analogous to an automatic tracking radar. The transducer is stabilized, and depth settings for fire control are derived from the tilt angle. Frequency is 15–25 kHz. Accuracy is 0.5 deg in bearing and tilt, 5 yd in range. The maximum range and maximum depth are about 2000 yd and 1200 ft, respectively, these figures corresponding to a 1945 Admiralty policy that new (near-term) weapons and sensors should be developed to deal with fast (15-kt) diesel submarines capable of diving to 1000 ft. These figures were changed in 1950 to 25 kt and 1500 ft; the earlier figures were incorporated in Types 164, 170, and 177. The Type 170 operator scans in depth and bearing, centering the beam using a CRT display; the CRT is flanked by separate paper recorders for bearing and range, with a fire-control unit alongside the range recorder. Limbo depth settings are taken directly from the transducer's tilt angle. Type 170B can accept visual and radar data (e.g., the location of a submarine periscope). It was to have had a means of correcting for water sound profile, but that was never developed. This production version automatically passes data to the FCS (initially UCSF 1, for both Limbo and Mk 20 torpedoes). The same stabilizer controls both the sonar and the Limbo mortar.

The Type 170/Limbo FCS staff requirement was stated in 1948, preliminary trials of the "four-square" transducer having

been conducted in 1947. Production of Type 170 began in 1952, and the first production 170Bs began trials in June 1954.

A solid-state version, Type 170M, entered service in 1974. Ships already fitted with Type 170 could be converted to 170M during their normal refits, as the transducer was not changed.

A version of this sonar, Type 171, was planned for submarines, but it was canceled.

Type 170 is used to control a Squid or Limbo mortar. Many ships in which it was the primary sonar were reequipped with PMS-26 (see that entry). Surviving Type 170 sonars: Bangladesh (*Umar Farooq*), Canada (as SQS-502), Chile (ex-HMS *Achilles* has 170B. The other *Leanders* have had their Limbos removed but may retain the sonar.), India (*Leanders*, *Betwa*, and *Trishul*), Indonesia (Tribal class), Iran (Vosper Mk 5 frigates and possibly *Damavand*), Malaysia (*Rahmat* and *Hang Tuah*), Pakistan (*Leander* class), United Kingdom (*Leander*-class frigates retaining Limbo mortars).

◆ Type 177

This set was the first British scanning sonar. Unlike U.S. cylindrical-transducer types, 177 used a flat transducer to scan a sector. This use was practical because the British transducer scanned electrically rather than mechanically, using electronic delay networks. In effect, then, 177 used preformed beams similar to those of the wartime German GHG (which in turn was the basis of the U.S. postwar BQR-2).

This sonar was designed in 1949. Sector operation was acceptable because it was assumed that the targeted submarines would be limited to a sustained speed of about 15 kt (see the note on the Admiralty staff requirement under Type 170); search rate was 40 deg/min, so a dual sweep over 80 deg took 4 min (during which time a fast submarine might move 5 kyd). Although such submarines could be tracked at long range, they had very high bearing rates at short range (typically 10 deg/sec) and were lost. When the 20–25-kt nuclear submarines appeared in the late 1950s, Type 177 had to be replaced (by Type 184).

Type 177 operated at 6, 7.5, or 9 kHz. The 4-ft² transducer consisted of 12 vertical strips (10 transducers each, in pairs, each pair being driven by a separate transmitter), producing 5 beams, each 10 deg wide. When transmitting, the sonar rippled its signal across, a technique (equivalent to RDT) also used in the later Types 184 and 2001. There were four 14-deg receiving beams (A, B, C, D). Type 177 produced a sequence of pulses: 5 long (150 msec), 5 medium (20 msec, at 225 Hz above the base frequency), and 5 short (5 msec, at 225 Hz below the base frequency). The entire sequence took 875 msec, and the pulse interval depended on the range scale: 7.5 sec for 5 kyd, 15 sec for 10 kyd, 30 sec for 20 kyd. Four pings were needed to classify a target; at 20 kyd, that series of sector scans required 2 min. A dual sweep over 80 deg took 8 min (4 min at 10 kyd, 2 min at 5 kyd). The expected performance was as follows: Under good conditions (isothermal water, sea-state 1–2), a ship at 12 kt could expect to detect a submarine beam-on at 18 kyd. In somewhat worse conditions (negative temperature gradient, sea-state 2–3), the expected detection range was 8 kyd. Under poor conditions (surface layer, sea-state 4–5), the expected range was 3 kyd. The bearing accuracy was 5 deg on doppler display, 1 deg on sector-scan display.

The displays were paper range recorders for the separate beams, plus a CRT for the doppler display and a CRT for the sector-scan display.

Type 177 was accepted for service in 1957, the first tests having been conducted in 1951 using a scaled-up Type 170 transducer. This sonar was roughly comparable to the U.S. SQS-4 series. No longer in Royal Navy service, Type 177 survives on board some ex-British ships: Chile (*Condell* and *Lynch*), Indonesia (Tribal-class frigates), and Pakistan (*Babur*).

◆ Type 181

The towed asdic repeater target (TART) responds to all sonar frequencies. TART simulates a real sonar reflection. Since its position is known (it is towed), it can be used to compare a

given sonar's measurement of range with actual range. Presumably, TART's signals show the appropriate doppler shifts, and it can, therefore, be used to calibrate the doppler features of sonars since its own speed through the water (on the end of a towing cable) is known and is measurable. In theory, TART might decoy an active-pinger torpedo seeker. However, antiship torpedoes generally use passive seekers. The TART towed body generally resembles that of the Type 182 decoy. The Graseby G 733 SLUTT (Ship-Launched Underwater Transponder Target) would seem to be an expendable version of TART.

◆ Type 182

See countermeasures below.

◆ Type 183

This emergency underwater telephone operates at 8–9 kHz. Range is about 1000 yd. Type 183P was a portable version.

◆ Type 184 and 184M/Graseby G750

Type 184 was the first operational British sonar to use a cylindrical transducer, in this case 3.5 ft in diameter (3.5 ft high) of 32 staves (each consisting of 13 barium-titanate elements). Some Type 184s may have had a slightly larger transducer (4 ft × 46 in, operating at 7.5 kHz). The dome, which can accommodate Type 177 as an alternative, is 157.25 in long, 64 in in maximum width, and 61 in deep. It is retractable.

Like Type 177, Type 184 operates at 6, 7.5, and 9 kHz, producing 45-msec pulses (originally 75-msec pulses for the special doppler sector, for narrower bandwidth). As in Type 177, Type 184 probably also has a long pulse (of 150 msec) for long range. Range scales or modes (equivalent to pulse intervals) are 5, 10, and 20 kyd. Operation is very different from that of the U.S. scanning sonars. Transmission is RDT: sets of 12 staves are excited in phase, producing an 11.25-deg (10-deg vertical width) beam, and then are excited in turn to ripple the beam around in 32 steps. A full cycle takes about 1.6 sec. For all-around reception, beam-forming networks produce 8 split beams (the complexity of the networks precludes any finer division of the incoming signal). The phases of signals received in each half-beam are compared so that directional accuracy within a beam is about 1 deg. Filtering (to avoid reverberation) blanks out passive reception for part of each pulse interval: for 5 out of 7.5 sec in Scale 5, and for the first 10 sec (equivalent to a range of 8 kyd) in Scales 10 and 20 (leaving, respectively, 5 and 10 sec for passive reception). Passive targets are displayed around the edge of the PPI. At least in the original version (using 45-msec pulses), the source level was 136 dB.

The sonar also forms a 90-deg-wide doppler sector consisting of four 22.5-deg beams (bearing accuracy is about half a beamwidth, or 10 deg). This beam can be scanned over 270 deg. It uses 21 doppler filters and can handle 40-kt doppler.

There are 2 electronic markers. One is manually set to measure range and range rate, then is rate-aided for semiautomatic tracking. The other is manually set in range and bearing. Both transmit their data to a ship's FCS. The manual marker can be used to select an audio channel in any sector.

Type 184 was conceived in 1955 as a big-ship sonar, primarily for self-protection but also for future ASW ships. It was originally intended to combine Types 177 and 176 in a single transducer on a time-sharing basis. However, tests against fast submarines (HMS *Explorer* and then the USS *Nautilus*) showed that something very different was needed. Although reliable to 8000 yd, Type 177 searched too slowly and over too narrow a sector (the fast submarines cleared it too quickly). Type 184 introduced all-around scanning, simultaneous active (against submarines) and passive (for torpedo detection) operation, and tracking of multiple targets. The 90-deg search sector replaced the 40-deg sector of a Type 177 and provided a sufficient data rate. All-around scanning overcame the tracking limitations of the earlier sonar.

Compared to Type 177, 184 achieved somewhat shorter max-

imum range (because it did not revisit any particular sector as often) but searched a much wider area. It also replaced Type 176, the passive self-protection set. An 18-kt ship equipped with Type 184 could detect a 45-kt steam torpedo at 6 kyd; the detection range at 24 kt was 3 kyd, and at 30 kt was 1.5 kyd, in each case about twice Type 176's range.

As the successor to Type 177, Type 184 was designed to make maximum use of 177's components: 30% were retained, 30% were modified, and 40% were entirely new (including the transducer).

In 1985 Graseby was reportedly supplying a modification kit that replaced the existing 8-sector display with a 16-sector display for greater accuracy. Transmission was at dual frequencies.

The main innovations in the Type 184 design were the display of echo doppler and the use of fixed transmission intervals with a dual-frequency system. A CRT was adopted for greater efficiency in target recognition and tracking and as an all-around and continuous torpedo alarm. Doppler was found particularly valuable against a fast submarine.

The Graseby G750 is an export version of the solid-state Type 184M, providing data directly to a fire-control computer. It could be supplied in both LF/MF and MF/HF versions, in each case with a 32-stave array. Sales, for installation on board *Leander*-class frigates: India (6) and New Zealand (3). The Indian ships were the first 4 *Nilgiri* class and *Godavari* (and probably the *Whitby*-class frigate *Trishul*). The *Nilgiri* sets are being (or have been) replaced by Canadian Westinghouse SQS-505s (hull and VDS). The last 2 *Nilgiris* were completed with French Spherion sonars. The New Zealand G750s remain, supplemented by FM 15/2 towed arrays.

In 1989 Graseby announced a Type 184 modernization program, originally developed for the Royal Navy. It has 3 phases.

Phase 1 is based in part on G750 experience. The original 8 Type 184 channels are replaced by 16 channels (i.e., beamwidth is reduced from 45 to 22.5 deg) for better bearing accuracy and better overall performance (there is less surrounding noise in a narrower beam). More than half the tubes in the original 184 are eliminated by the introduction of solid-state electronics. All electromechanical selectors and timers are replaced by solid-state devices.

In Phase 2, 31 accurate digital filters are inserted in each of the sonar's 4 doppler beam channels; the sonar can then measure up to ±40 kt of target doppler with a resolution of 3 kt. Solid-state power amplifiers replace the original tube amplifiers, and a microprocessor-based signal-monitoring and fault-detection system (BITE) is added. In this phase the transmitter, monitor, doppler display, and hydrophone effect (passive) systems are all replaced; this completes all major work in the sonar instrument space.

Phase 3 provides 3 separate geographically stabilized memory color displays: DD (doppler display), PPI, and HE (hydrophone effect, i.e., passive). Phase 3 is applicable to existing G750 sonars. This is the phase concerned with the sonar control room.

Total installation time is 5–6 weeks.

Type 184P modernization in the Royal Navy began in 1987. By April 1989, 29 ships had received Phase 1 improvements. Phase 2 had been completed in 4 ships. The preproduction Phase 3 model was delivered in mid-1989. The Royal Navy was reported as very well satisfied with the Phase 1 and Phase 2 improvements, the sonar benefiting from much increased availability and reliability, and the operators being pleased with smooth tracking leading to better performance. However, the program is proving protracted, not because of any problem with the prime contractor or with the equipment, but because of the multiple competitions required for each contract for each phase. As a result, total program length will be about 10 yrs, and much of the savings to be expected will be lost because of the need to maintain so many of the obsolete Type 184s for much of that time.

The 184 modernization program presumably incorporates the technology being offered separately in the form of Sea Searcher (see below).

◆ Type 185/Graseby G1732

An underwater telephone (8–9 kHz), the Graseby G1732, advertised about 1976, is a modernized version for high-speed data transmission. This system may have been associated with British work on having nuclear submarines provide direct support to surface ships, the submarine acting, in effect, as a VDS and passing its data to a nearby surface ship. Reportedly, British experiments using HMS *Dreadnought* preceded U.S. interest in the direct-support mission.

Frequency is 8.9875 kHz. Data are transmitted and recorded automatically, at up to 66 words/min.

Type 185 was superseded by Type 2008.

◆ Type 186

This passive MF sonar for submarines ("Knout"), introduced in 1956, was an adapted German GHG. It was, therefore, analogous to the U.S. BQR-2. One pair of arrays was on each side of the submarine, operating at about 1 kHz. Targets were sought by circling at slow speed or by following a sinuous course. With beam steering, this system became Type 2007.

◆ Type 187

An active-passive sonar for submarines (LF to MF), Type 187 is an adapted Type 718, with an added low-power mine-detection sonar. The sonar consists of a 5-ft-wide flat transducer rotated mechanically inside a streamlined dome with a maximum diameter of 72 in (length 192 in, height 57.5 in). Using split-beam techniques, this system can achieve a bearing accuracy of about half a degree.

In the Canadian SOUP refit program, the mechanically trained transducer head was replaced by a phased array.

Type 187 trainable sonar transducer with its sonar dome removed, on board a British *Oberon*-class submarine, 1988. The individual spot transducers can just be distinguished; the sonar is trained broadside. (A. Raven)

◆ Type 189

Type 189 is a cavitation indicator.

◆ Type 193

See the Mine Warfare section under countermeasures.

◆ Type 195/2069

The standard British helicopter dipping sonar was manufactured by Plessey. Type 195 was conceived in the late 1950s, ran pre-production tests in 1964–65, and entered service in 1966. The basic design was modernized in the mid-1970s, and production (of the final 195M version) ended in 1985. This sonar was a building block of Plessey's PMS 26 and 27.

The flat-faced transducer (10.8 × 38.4 × 7.3 in, 130 lb) consists of 4 vertical staves (13 elements each) covering a 90-deg sector. The staves are excited in turn to form a sweeping beam, and a delay-line network produces 3 receiving beams, each about 30 × 4.7 deg at 10 kHz. Pulse widths are 5, 25, and 40

msec. Phase comparison within each beam makes for a bearing accuracy of 3 deg. Operating frequencies are 9.5, 10, and 10.5 kHz, and range scales are 3, 6, 9, and 12 kyd. Typically, the sonar emits 2 pings in each 90-deg sector, then trains 90 deg for a new set of transmissions (an operation requiring 3 sec). Range accuracy is 1.5% of the scale selected. Type 195 was originally designed to achieve a range of 6000 yd under average conditions (3000 yd against a submarine below the layer, or 8000 yd if both transducer and submarine were below the layer), but that assumed that the sonar was deployed from a noisy piston-engined helicopter. Performance improved considerably when quieter gas-turbine helicopters entered service. In the original form, Type 195's peak power was 6.5 kW (source level was 129 dB).

The 45-lb transducer (in a 120-lb fish) is on an 800-ft cable. On-board electronics dead-reckons between dips so that the helicopter can maintain contact as it approaches its target. A doppler display is used for initial detection. The fish includes a BT to measure the sound-velocity profile. The maximum instrumented range is 8000 yd.

Type 195 is generally carried on board a Sea King helicopter. It was apparently offered to buyers of Lynx but proved rather heavy (a Dutch order was probably canceled in favor of DUAV 4). Users are Australia (Sea King Mk 50), Argentina (7 Italian-built Sea Kings and 2 Lynxes), Canada (31 CH-124s; replaced by AQS-13), Egypt (18 Sea King Mk 47s), India (Sea King Mk 42), Pakistan (6 Sea King Mk 45s), and the United Kingdom.

Type 2069 is an upgraded 195M, capable of operating at a greater depth (1000 ft) and of being integrated with an AQS-902 acoustic processor. At present the Royal Navy is the only user of the improved Type 2069 (44 purchased).

◆ Type 197

This sonar-intercept gear (French Velox system) consisted of a hydrophone atop the sail. Claimed accuracy was a few degrees, but in service this set could reportedly determine the direction of an active sonar transmission only to within a 90-deg quadrant.

◆ Type 199

A VDS, Type 199 is the British version of the Canadian SQS-504. The Canadian sonar was based on Type 170 in a towed version of the British 100-in dome. Development began in 1956, the first prototype being completed in 1961. Type 199 entered Canadian service in 1962. Although the Admiralty bought Type 199 in 1960, it did not enter British service until 1968; and all units were gone by the late 1970s. Type 199 survives in New Zealand (the frigate *Southland*). On board the Indian *Leander*-class frigate *Nilgiri*, Type 199 and the British G750 hull sonar have been or are being replaced by the Canadian Westinghouse SQS-505 (hull and VDS).

◆ Type 718

This postwar low-frequency (2.5 kHz for slow submarine speed, 10 kHz for high submarine speed) hydrophone is designed to obtain accurate bearings. Typically mounted topside, it is a split-beam. See also Type 187 above.

◆ Type 719

This postwar azimuth scanning hydrophone for submarines was designed for torpedo detection. Type 719 consisted of a hydrophone and a parabolic reflector. Originally to have been mounted in the keel, Type 719 was eventually installed in submarine sails, pointing aft. It was introduced in the postwar streamlined "T" and *Porpoise* classes.

◆ Type 2001

This British first-generation bow sonar for nuclear submarines was developed by Plessey. Type 2001 introduced conformal-array techniques. It was characterized as a bottom-bounce (rather than convergence-zone) set. Type 2001 was succeeded by Type 2020. Type 2001 was designed specifically for the prototype sub-

marine, HMS *Dreadnought*, one of whose design missions was the direct support of surface ships. It was, therefore, considered particularly important to be able to isolate or cancel out the noise of those ships. Much of the data that follows is taken from the 1958 design study, and they are probably very close to the characteristics of the set as actually manufactured.

Type 2001 was designed for both active and passive (long- and short-range) operation over a 240-deg arc around the submarine's bow, using a horseshoe-shaped array. It was initially to have been combined with a Type 719 rearward-looking passive searchlight, but that may not have been done; Type 719 would have fed the 2001 displays. The design included provision for feeding sonar data directly to the FCS (TCSS 5) and to the AIO. Because the same array had to function in both active and passive modes simultaneously, particular attention had to be paid to avoiding interference between the 2, by choice of frequency. A study showed that the optimum active frequency was 3 kHz, and the optimum passive frequency was 2 kHz for search and 6 kHz for short-range fire control.

The array itself was a 6-ft-high horseshoe about 40 ft long, its 87 staves (14 elements/stave, for a total of 1218) tilted back at an angle of about 20 deg for streamlining. The total weight was estimated at 20–30 tons. This array produced a total of 24 beams (about 10×16 deg) for active search. Normally, the beams tilted down 20 deg to compensate for the array's shape, but they could also be tilted another 20 deg for bottom bounce (the 1958 study showed no interest in either surface bounce or CZ operation). As in the major surface-ship sonars (177 and 184), the beam was rippled from one end of the array to the other. The planned source level, limited by cavitation, was about 137 dB. The pulse length was 200 msec at 3.25 kHz at range scales of 20 nm or more, or 100 msec at 10 nm. Returning pulses would be processed with 15 doppler filters, each 8 Hz wide (equivalent to a total of ± 30 kt). To catch short-range targets, a ripple of 20-msec pulses (at 3 kHz) always followed the main long pulse. It was processed in a 40-Hz filter (the doppler for ± 10 kt). There was also a separate active attack/classification mode, using a long FM pulse (1.25 sec at 3.5–3.8 kHz). Thus, at 20 nm a full scan would require 5.5 sec plus 1.25 sec for the special FM pulse. The sonar would probably require another 0.5 sec to begin to respond to echoes, so at worst it might miss targets 5800 yd away (4800 if the FM pulse were not used).

By 1958 experience with Type 177 showed that under some circumstances splash over between beams could cause problems in the ripple transmission. Type 2001, therefore, had an alternative, lower-powered ODT (broadcast) mode, in which case any target farther out than 600 yd could be detected.

The 24 long and 24 short pulses would be displayed separately on port and starboard CRTs for initial coarse target-bearing detection [range vs. bearing [waterfall] for the short pulses, doppler for the long pulses]. In 1958 CRT technology would not support large displays, and it was suggested that Type 2001 use the contemporary RAF radar technique of automatically photographing a small CRT, developing the film, and then projecting the result about 15 sec later. This technique actually was used in AIOs and probably in early Type 2001s.

Between the main displays was an additional CRT to show the sector in which the long FM pulse was used for attack or classification. This display had to be direct because a long time delay could not be tolerated during an attack. The central part of the sector display, corresponding to perhaps 160 yd in 1000, could be expanded in 8 increments for target classification (a technique equivalent to the contemporary U.S. ASPECT). Under cruising conditions the sector display would not normally be manned, its operator relieving one of the search operators. In combat, the port or starboard operator would initially detect a target and cue the sector operator onto it.

Another problem was range estimation. Type 2001 was expected to detect some targets as much as 60 nm away, and cursors were notoriously inaccurate at much shorter ranges. The solution was a range clock, set to run at the speed of sound, that clicked off every 100-yd interval. Presumably, it set a

counter when an echo was received; this was a very early approach to automatic target detection.

Type 2001 was designed to operate passively at 1.5–2.3 kHz; 2.5 would have been better but would also have suffered from reverberations from active transmissions. For greater precision, a second passive channel, at 5.5–6.5 kHz, was provided (with the second harmonic of the main active frequency, about 6 kHz, blanked off). For passive operation, the sonar formed 47 beams, each 10 deg wide, at 5-deg intervals (in active operation only half the beams were used). The passive signals were displayed on the main initial-detection displays, and there was also an audio channel for the sector-display operator.

All beams were formed by delay lines. That made for an additional problem. Ideally, the set had to be geographically stabilized to cancel out own-ship motion. However, such stabilization required continuous changes to each set of delays, an inadmissible complication (but one relatively easily handled in a fully digital beam-former of current type). The main displays, then, were stabilized in 5-deg steps. Only the sector display (for attack) was continuously gyro-stabilized.

The prototype Type 2001, evaluated on board HMS *Verulam*, had flat panels instead of individual staves; that was probably the configuration ultimately adopted. Scaled up from the version on board this ship, the transducer almost certainly consists of 24 panels, each 2 ft wide and 6 ft 9 in high and each carrying 56 spot transducers. Type 2001 was built, then, as 24 parallel sonars. Such a design should have simplified production (transducer alignment) as well as the beam-forming problem.

Type 2001 (AA) is in the eyebrow position in *Valiant*-class SSBNs. 2001 (BC) is in the chin position (*Swiftsure* class).

◆ Type 2004

Type 2004 is a submarine hull-mounted sound velocity meter, for sonar performance prediction. Such predictors are used to help sonar operators choose optimum operating modes. They also help in the interpretation of sonar data, since the predictor can estimate ray paths.

◆ Type 2005

Type 2005 is the French DUUX 2A passive range-finder.

◆ Type 2006

Type 2006 is the U.S. AN/BQQ-3 LOFAR detector/classifier (see U.S. sonars below).

◆ Type 2007

This LF passive flank array for submarines is a replacement for Type 186. Type 186 used fixed beams, but 2007 can steer them electronically. It operates at 1–3 kHz and is used for initial detection, bearing resolution, and limited TMA. Each of 2 flank arrays has 24 hydrophones. This system can also use a towed array, and existing 2007s are being converted to towed-array use. 2007 is otherwise now leaving service.

The requirement was stated in the late 1960s, and the array was developed by British Aerospace; the first unit entered service in 1971. Later units were manufactured by Graseby Dynamics. Type 2007 was bought for Australian, Brazilian, Canadian, and Chilean *Oberons*. The addition of a TAPS processor converts Type 2007AA to Type 2007AC, with greater sensitivity and better target discrimination.

When the submarine is moving so fast that noise drowns out the flank array, the Type 2007 display can be connected to the towed array.

◆ Type 2008

This HF underwater telephone ("say again" machine) replaces Type 185. This set is also used as a short-range passive sonar. Many navies apparently use their underwater telephones this way, since they provide wide-band omnidirectional reception. Type 2008 uses 3 fixed transducers and 2 small trainable ones in the sail.

◆ Type 2009

Type 2009 (UARS: underwater acoustic recognition set) is a secure multitone-simplex communications and encoding device. It is IFF and uses G-tone codes for challenge and reply.

◆ Type 2010

Type 2010 (ACUTE) is an acoustic teletype, working with Type 2008 and coding its signals for better resistance to jamming and for automatic error detection. Reportedly, tests showed that the use of an automatic error-detecting code made for 98% accurate reception and ultimately for several-fold improvement in transmission rate and in effective range.

◆ Type 2011

Type 2011 is a noise target.

◆ Type 2012

Type 2012 is a passive sonar-classification set, presumably replacing 2006.

◆ Type 2013

Type 2013 is a bathythermograph.

◆ Type 2014

An Acoustic Ray Trace Indicator (ARTI, sonar ray path predictor), this set was intended to guide ships using VDS (Types 195 and 199) in setting sonar depth. Type 2014 is now obsolete.

The ray trace is shown on a CRT, which can be photographed for record purposes. This device was marketed as ARTI (acoustic-ray-trace indicator). It was particularly associated with Type 199 but was carried by some submarines.

◆ Type 2015

Type 2015 is an expendable bathythermograph (XBT).

◆ Type 2016/2020/2028

Type 2016, an MF hull sonar introduced in the Type 22-class frigates, was the first British sonar with substantial computer assistance. In the Falklands 2016 was credited with the ability to overcome multiple reflections and, thus, to distinguish an Argentine submarine on the bottom. The Type 184 equipping other British frigates seemed to have no such capability. On the other hand, 2016 was criticized for its lack of direct output, in the form of headphones, and thus presumably for its poor passive performance.

The replacement for 177 and 184M, Type 2016 uses 2 transmitters operating at 5.5, 6.5, and 7.5 kHz; the broad variation in frequency helps avoid intership interference. Operating modes are ODT (omnidirectional transmission) and SDT (steered directional transmission). Capabilities include automatic target detection and tracking.

The cylindrical transducer consists of 64 staves, each of 12 elements. There is also an auxiliary 12-element vertical array that can be rotated around the main transducers to monitor transmission close to the transducer so that the distant transmission characteristics can be estimated. There are 2 horizontal beams, 1 nearly horizontal and 1 dipped at 7 deg, to penetrate beneath the surface layer. The horizontal beam pattern consists of 32 pairs of beams, presumably chosen so that Type 2016 can follow targets by beam-splitting. Total transmitter power is 44 kW. The associated computer is a Ferranti FM 1600B with 64k memory.

The 6-ft-diameter array is mechanically roll-stabilized, and it can retract into the hull. The sonar uses 5 electronics cabinets for receivers (4 active, 1 passive), 2 others for transmitters, and another for T/R control circuits. The signal processor occupies 3 separate cabinets with another for computer spares.

There are 3 side-by-side consoles, each with a circular CRT, keyboard, and roller ball. Units above the main CRTs are used for communications and show readouts of ship's parameters. The left-hand display is used for classification/tracking (doppler

B-scan as well as A-scan for target details, using ASPECT). This CRT can show a blow-up of part of the surveillance display, either in B-scan or as a cut through the beam in a vertical plane. The center CRT is used for surveillance (PPI), and its data can be passed to the AIO; it is also used to monitor system performance. The right-hand console is passive (including all-around torpedo warning). It is normally used for passive target tracking (bearing-time waterfalls show target histories) and to show frequency ranges. There is also an auxiliary display, on which data can be logged and such information as bottom conditions and sound speed displayed. Normally, the operator sits at the center (surveillance) PPI, supported when necessary by an operator at the left-hand (tracking) display. The system incorporates an automatic torpedo alert to AIO.

In cruising status, the system has 1 operator at the center (PPI) console, supported when necessary by an operator at the left-hand (tracking) display.

Type 2016 was manufactured by Plessey, although Ferranti is responsible for signal processing (which uses an FM 1600B computer). Ferranti began research into computer-aided sonar in 1967, working with the AUWE: the objective was to improve the operator's detection performance and the quality of sonar data passed to the computer combat system. Work on the associated sonar began in 1971, a prototype running sea trials on board HMS *Matapan* in 1971–76. An operational prototype was tested in 1978 on board HMS *Broadsword*. A total of 34 were built for Type 22 and Batch 3 *Leander*-class frigates, for later Type 42 destroyers, and for the *Invincible*-class aircraft carriers. 2016 is to replace Type 184 on board retrofitted Type 42 destroyers. Type 2016 in turn will be replaced by Type 2050. Three of 4 Type 42 Batch 3 destroyers were completed with 2016, and it has now been back-fitted in two Batch 1/2 ships.

Type 2020, a second-generation sonar for nuclear attack submarines, is the submarine version of Type 2016. 2020 is in the *Trafalgar* class, replacing Type 2001. 2020 uses steered pre-formed beams (DIMUS). Reportedly, active frequencies are 5.5–5.7 kHz, and passive operation is at 2–16 kHz. Type 2020 is designed primarily for passive detection, including the use of bottom-bounce and CZ modes. Features include automatic tracking for reduced workload. There is a manual override.

The upgraded version of Type 2020 is designated MODEX. It uses 2 Ferranti universal raster-scan (i.e., television-like) displays for both passive and active data, replacing the earlier curvilinear PPIs. Reportedly, the universal screens make for faster operator reactions during close contact or in torpedo evasion. The original hard-copy (paper) displays are retained for mission analysis. In addition, plasma touch-panel displays replace the earlier keyboards.

The Type 2020 requirement, for *Trafalgar* class, was stated in 1976–77, Plessey receiving a contract in 1977. 2020 was tested in 1981/82, the first production delivery following in October 1982 for HMS *Tireless*.

Type 2028 was a smaller version of 2016 but was not procured.

As of 1990, a bow-mounted version of 2016 (for the *Sheffields*) is out to tender.

◆ Type 2017

Type 2017 was a spectral analyzer (now obsolete).

◆ Type 2018

Type 2018 is a submarine DEMON frequency analyzer with LOFARgram output (DIANA).

◆ Type 2019 (PARIS)

This sonar intercept gear was developed under the British/French/Dutch PARIS (Passive/Active Range-and-Intercept Sonar) program. 2019 covers up to 360 deg at 2–14 kHz. It is installed in modern submarines, including *Upholder* class (in which an active pinger is added). The project began in 1965, a prototype being built in 1968–69. Thomson-CSF was prime

contractor. The Royal Navy placed its contract in 1973, testing a prototype in 1974–75 and ordering its first sets in 1977. Type 2019 is currently being modernized.

In *Trafalgar*-class submarines, Type 2019 is located forward of the sail, in a small sonar dome on deck.

◆ Type 2021

Type 2021 is an expendable bathythermograph (XBT).

◆ Type 2022

Type 2022 is an acoustic beacon.

◆ Type 2023

This towed array for ballistic missile submarines is based on the U.S. BQR-15. 2023 uses a British array and U.S./British electronics and is retrievable, the array being stowed in the ballast tankage. The requirement was stated in the late 1960s, Plessey receiving the R&D contract early in the 1970s, roughly simultaneously with 2024. Arrays were installed during major overhauls. In the early 1980s TAPS, a towed-array broad-band processing system, was added. Reportedly, it reduces the stern null, i.e., allows the sonar to form narrower beams. This array also has a 3D heading-reference sensor (by Ameeco).

Reportedly, Type 2062 was developed as a replacement, the cost of BQR-15 wet-end spares proving very high.

◆ Type 2024

A clip-on towed array for nuclear attack submarines, 2024 is installed on board *Valiant*- and *Swiftsure*-class submarines and on board the first 2 *Trafalgars*. 2024 in turn is being replaced by Type 2026. Existing arrays are being fitted with the new broad-band TAPS processor. Because 2024 is a clip-on array, at least 1 has been lost to underwater obstructions. In the Falklands War, HMS *Conqueror* reportedly used her array to track the Argentine cruiser *Belgrano* from beyond the horizon, keeping station for 2½ days.

The contract was let in 1970, followed by preprototype tests in 1974 and service in 1975. Reportedly, 2024 uses an Ameeco wet end designed by AUWE, a Plessey beam-former, and a Scientific Atlanta waterfall display. 2024 typically uses the Type 2035 processor.

◆ Type 2025

Type 2025 is an expendable bathythermograph (XBT).

◆ Type 2026

This British/Dutch second-generation towed array for attack submarines uses a stronger cable, more sensitive hydrophones, and improved reception. 2026 has a new broad-band LF processor and an updated narrow-band processor. A photograph of the display shows 3 large CRTs, a configuration that suggests that 3 octaves are covered. Type 2026 was developed in tandem with 2031(I) to replace Type 2024. As of 1986, 5 British and 5 Dutch arrays were on order.

Marconi Underwater Systems received the R&D contract for this array in 1977–78, the Royal Navy specifying a clip-on with a stronger array. 2026 was tested in 1983–85. Meanwhile the Royal Netherlands Navy negotiated for 5 (concluded late 1985). The array was approved for service use early in 1986. Type 2026 entered British service in 1987.

Type 2026 normally employs a clip-on array attached to the port stern plane. However, recently HMS *Turbulent* tested a reelable array, the winch for which was housed in a hump visible aft, above the waterline. Presumably, the array itself was stowed in the narrow space between pressure and outer hulls. The Type 2026 processor can be used to classify signals from the intercept sonar and the Type 2008 underwater telephone.

Reportedly, the Dutch version, for the *Walrus* class, uses a Signaal display processor, a Marconi beam-former, and an Ameeco wet end.

This sonar is described officially as Integrated Sonar Phase I.

◆ Type 2027

Type 2027 is a prototype passive-ranging sonar using the 2001/2020 array.

◆ Type 2029

Type 2029 is automatic digital sonar-intercept gear.

◆ Type 2030

Type 2030 is classification equipment: Spectral Dynamics's 2-channel spectrum analyzer with waterfall display (U.S. AN/BQR-22).

◆ Type 2031

Type 2031 is the British towed-array sonar for surface ships. Unlike the U.S. Navy, the Royal Navy uses its towed-array frigates not only tactically but also for surveillance; the RN, therefore, requires greater ranges, achieved by a combination of lower frequency (presumably longer arrays) and more processing. There are 2 versions: 2031(I) for 4 frigates operates at low speed and has relatively simple processing; 2031Z, for Type 22 frigates (Batches 2 and 3) operates at a higher tow speed. All combine broad- and narrow-band processing.

Reportedly, 2031 is a 5-octave system. Type 2031Z incorporates the newer (ca. 1983) Curtis processing architecture, which drastically cuts computer requirements. The Curtis processor is a very fast special-purpose digital computer with a fixed program and over 100 Mbytes of memory. In 1987 it was reported that 2031 is normally trailed more than 1600 m astern, at speeds of 8–10 kt down to 2–3 kt; reported range is "over 100 nm," which presumably means at least 3 CZs (105 nm in the Norwegian Sea).

Reportedly, the array is 89 mm in diameter and over 500 m long, i.e., twice the length of an SQR-19 [3.5 in × 1640 ft].

The initial R&D contract was awarded to GEC Avionics in 1971/2, followed by trials on board HMS *Matapan* and *Lowestoft* in 1978/81, four 2031(I) being installed on board modified *Leanders* in 1982. A fifth was built as a spare. Thirteen 2031Z were purchased.

The associated processor was the GEC Avionics JASOND (1976), the first British digital 360-deg towed-array processor. It was first tested on board a British submarine. JASOND was based on the earlier Sonalyzer (1974), used as a 4-channel sonobuoy mission replay unit.

Type 2031Z reportedly embodies a new (Curtis-architecture) processor, developed by AUWE, which drastically reduces weight (by 60%) and power requirement (by 80%) and is also much less expensive than its predecessors. The equivalent submarine sonar is Type 2046.

Type 2031 handling gear, HMS *Phoebe*, 1990. (Leon van Ginderen)

◆ Type 2032

This add-on package to extend the capability of a submarine's bow sonar includes a special transducer and beam-former; 2032 complements Type 2020. 2032 uses 15 modified (detuned) hydrophones within the 2001/2020 bow array for LOFAR. It was first delivered in March 1989 (Ferranti).

◆ Type 2033

Hydrographic survey-ship sonar.

◆ Type 2034/2053/Sonar 3000 PLUS

Dowty's (Waverley) dual (left- and right-hand arrays) side-scan sonar has been in British service since 1976. The current version of the towed body ("towfish") is Mk 3. Sonar frequency is 110 kHz (100-msec pulse), and range scales are 75, 150, and 300 m (PRFs of 10, 5, and 2.5 pps). Over 50 units are in current use by the RN Hydrographic Service.

Sonar 3000 PLUS is a family of side-scan devices developed from 2034, and Sonar 3010 has been proposed as a mine locator (analogous to the U.S. Klein Mk 24; see the Mine Warfare section). Sonar 3010 adds a higher-frequency (300-kHz) mode for short range and high precision (37.5-m scale) and can mark a target.

Type 2053 is the British designation for Sonar 3000.

◆ Type 2035

BQR-23 processor used with the Type 2024 array (16-channel waterfall).

◆ Type 2038

This surface-ship towed array, planned as a 2031I successor, was canceled because of the success of the Curtis-architecture 2031Z.

◆ Type 2040

This sonar for new British diesel submarines (*Upholder* class) is based on the French Thomson-CSF "Argonaute" passive system. 2040 was a British/French/Dutch development of the French Eledone (DSUV 22). The Dutch system is called Octopus.

The system as a whole consists of a circular bow transducer with a separate active transmitter (usually in the sail), plus a passive sonar interceptor (PARIS, Type 2019).

There are 3 types of bow transducers, with 32, 64, or 96 staves; but only the 64-stave version is in service in the 3 navies. The 32-stave version was proposed for the abortive CA-type French export submarine. The passive mode uses 128 preset LF channels. It can track 12 targets simultaneously, and it interfaces with the submarine's FCS. The FCS uses Type 2040 data for its TMA solution.

The original Thomson-CSF system was a new passive/active commercial venture intended for the French submarine program of the late 1960s and early 1970s. The French *Agosta*-class sonar requirement was issued in 1971, Thomson-CSF offering its Eledone system and receiving an update contract (development 1971–76, tests 1975–76, approval for use 1976 as DSUV 22). Octopus was developed specifically for the Dutch *Walrus* class, and a further development won the British competition in 1982 for Batch I *Upholder*-class submarines. Octopus was ordered in 1984.

As installed in an *Upholder*, Type 2040 has a 64-stave (3-m-diameter) cylindrical passive array on the bow forward of the torpedo tubes, and a smaller-diameter cylindrical active sonar in the sail (mechanically rather than electrically trained). The bow array differs from that of the original French system in having 3, rather than 2, tiers of staves. 2040 requires 4 processing cabinets for its 4 operating modes (adaptive, active, passive, and intercept). There are also flank arrays and a towed array. Up to 12 targets can be tracked simultaneously, data from each of the 12 threat channels feeding into the automated combat system for TMA. By using combinations of the 12 channels, the sonar can determine direction to within 0.1 deg.

The display uses a color CRT to display signals from different sensors (or from different operating modes) simultaneously, for correlation and, therefore, classification. For example, the display can easily distinguish between a helicopter's sonar (which shows up only on the intercept sensor) and a ship's hull sonar (which will be accompanied by propeller sounds, visible on the combined display).

◆ Type 2041

Upholder-class passive ranger.

◆ Type 2042

Self-protection (presumably decoy) submarine system.

◆ Type 2043/2044/2045

These are elements of the Trident integrated sonar (Type 2054). Type 2043 is the active/passive bow sonar; Type 2044 is the towed array; and Type 2045 is the sonar intercept receiver. The separate Type 2043–45 designations are no longer used.

◆ Type 2046

This core processor/display for submarines' towed arrays embodies Curtis architecture (see separate entry). It is a 3-octave system. There are 4 adjacent operator positions, each with a CRT and a flat electroluminescent panel beneath it. Type 2046 has some hardware in common with 2031Z, but is even more compact; the signal processor is housed below the displays.

Compared to Type 2024, Type 2046 reportedly provides an improved narrow-band search capability; the associated towed array uses fiber optics to transmit data from array to submarine.

The Type 2046 designation has also been applied to the submarines' towed arrays themselves, the replacements for Type 2024s. As of 1987, a total of 27 had been ordered, the first having been delivered that year.

◆ Type 2047

Plessey's wide-band hard copy (pen output) analyzer covers 5 Hz–3.2 kHz and produces up to 12 LOFARgrams simultaneously. 12-channel narrow-band processor to replace 2035. Type 2047(AC) is a 16-channel processor for the 2024 array.

◆ Type 2048 (PMS 75)

Plessey's Speedscan is a display that allows a conventional Type 193M minehunting sonar to function in side-scanning mode. The transducer is trained 90 deg on the beam, and Speedscan records the echoes obtained. Its beam-former transforms these data into a map of a strip of the bottom, using 3 pings for each point in the map.

◆ Type 2050

Ferranti's bow-dome sonar for Type 23 frigates is the successor to Type 2016 and reportedly uses the same transducer but a different signal processor (although the new bow location suggests a larger and lower-frequency sonar). 2050 is credited officially with an excellent software-based ability to reject bottom echoes, for good performance over the continental shelf.

2050 is an upgraded version of the Ferranti FMS 21 export sonar. Operating at 4.5–7.5 kHz, with sixty-four 5.5-deg beams, 2050 should be capable of BB and CZ operation. Four electronic cabinets replace the 12 of 2016. The requirement included digital operation and simpler (more maintainable) electronics. Type 2050 is a fully digital sonar; the array is sampled by the pre-processor, and signals are digitized before passing into the beam-former. The sonar requires a total of 5 cabinets, including 1 for target classification and 1 for data-display handling. Type 2050 uses Curtis architecture and has the same type of console as Type 2054; it incorporates 25 M700 microprocessors.

Unsuccessful competitors were the Plessey PMS 46 export sonar and a Marconi sonar.

Trials of a hull-mounted version began in 1986 on board HMS *Jupiter*, followed by sea trials in 1987 on board HMS *Scylla*. As of 1987, a total of 17 Type 2050s were on order, the first pro-

duction unit having been delivered in mid-1987. As of mid-1989, the Royal New Zealand Navy was evaluating a version of 2050 on board HMNZS *Tui*, prior to buying the sonar for its *Leander*-class frigates.

Unit cost of Type 2050/2051 is about \$4–5 million (1990).

◆ Type 2051 (Triton)

Type 2051 is a new sonar for the modernization of diesel-electric submarines. Plessey (with Ferranti and GEC Sonics) won the contract in 1985. 2051 is a partially integrated sonar using an active/passive bow array in a new streamlined bow dome, a broad-band bow processor, 2 conformal flank arrays (2-octave narrow-band processor), an intercept sonar, and a clip-on towed array. The bow array has 32 preformed beams in a new low-noise dome. 2051 is a full upgrade rather than a simple replacement of Type 186 by Type 2007. 2051 was the first fully integrated British sonar, using 4 Ferranti multipurpose displays with plasma touch panels. 2051 was developed to compete with a system offered by Thomson-CSF. The R&D contract went to Plessey/Ferranti/GEC Sonics for an upgraded FMS 12, leading to R&D in 1982–84.

The prototype was tested in HMS *Opossum* (which had the first British GRP submarine bow); the first production set was in HMS *Otter*. Triton is the commercial name, Plessey acting as design authority. Triton 1 is the *Oberon* suite, and Triton 2 has been offered for follow-on Type 2400s. The manufacturers claim that Triton 2 is 15% less expensive than *Argonaute* and 10% less expensive than the German CSU 3-4 used for Australian *Oberon* upgrades.

Three Type 2051s, originally ordered for the Royal Navy, were provided for refits of the 3 Canadian *Oberons*, and this sonar was also offered to Malaysia (presumably for submarines that country planned to buy). The Canadian ship sets were diverted from Royal Navy production.

◆ Type 2052

This interim clip-on towed array for nuclear attack submarines is intended as an upgrade for older units; it is derived from Type 2024. This Type number has also been used for the Marconi TAPS (towed-array processing system) broad-band signal processor. Passive broad-band towed-array sonar used with 2024 for submarines lacking Type 2007 (SSNs prior to *Swiftsure* class). This is the basis of the Marconi GETAS export system.

◆ Type 2053

Waverly's hydrographic side-scan sonar has advanced digital processing (naval version of Sonar 3000); see Type 2034.

◆ Type 2054

Plessey's sonar suite (active/passive/towed passive) is for British Trident strategic submarines. The requirement was issued in 1983, proposals following in 1984; Plessey was chosen early in 1985. 2054 includes a Sub-Harpoon missile capability. Signal processing is entirely digital, the signals being transformed to digital form before being passed to the beam-former. That process may be unusual among modern sonars. This system employs a Type 2043 active/passive sonar, a Type 2044 towed array, and a Type 2045 intercept sonar. These subdesignations are no longer used.

Plessey is responsible for the bow sonar, the beam-former, and the signal processor; Marconi for the intercept sonar; and Ameeco for the towed array. There will be 5 consoles, each with two 17-in display screens and touch-sensitive plasma control panels.

The associated sonar-activated FCS is SAFS 3. The tactical data-handling system is DCC(BN).

The preproduction version of Type 2054 was completed early in 1989.

◆ Type 2057

This is a new surface-ship/submarine towed array to replace both 2031Z and 2026/2046. It is to be much longer than that of

2031Z, to operate at lower frequencies. The 2 competing teams, both of which received 18-month contracts in 1989, consist of Plessey leading GEC Avionics (Sonar Systems Division) and Ferranti (supported by the Communications Division of Dowty Marine). A winner will be chosen in 1992, and Type 2057 should enter service in 1995.

There is no announced Royal Navy program for a multiline array.

◆ Type 2058 (Soundtrak)

Type 2058 fish. (Author)

Thorn-EMI's towed sound source for acoustic ranges is proposed as a component of Vosper-Thorneycroft's Sea Serpent multi-influence towed mine-countermeasures array. The free-flooding towed body is based on that of the Type 182 decoy, and Type 2058 is towed from the Type 182 winch.

◆ Type 2059

Type 2059 is an HF sonar, developed by Edo Almondbury, used to track PAP 104 minehunting vehicles; it has also been used to track submarine rescue vehicles. The 3-in transducer is set at 22, 23.5, 25, 26, or 28 kHz, and the transponder aboard the vehicle replies at 30 kHz. The very short receiving array detects transponder-signal direction by comparing the phase differences between its receivers; the computed position of the vehicle is transmitted directly into the ship's tactical data system. Multiple frequencies allow a single Type 2059 to track 5 targets simultaneously.

◆ Type 2060

Surface-ship XBT to replace 2015.

◆ Type 2061

Waverley's single-console Curtis-architecture processor is for Polaris strategic submarines. This interim narrow-band processor is being replaced by 2046.

◆ Type 2062

The replacement for the Type 2023 SSBN towed-array sonar, Type 2062 uses a Waverley dry end based on that of Type 2031Z and an Ameeco wet end. 2062 is being replaced by Type 2046.

◆ Type 2063

Submarine self-noise monitor.

◆ Type 2064

Reportedly, minehunter tracker.

◆ Type 2065

Experimental retractable thin-line array.

◆ Type 2066

Dowty surface-ship torpedo countermeasure.

◆ Type 2067

Underwater tracking system.

◆ **Type 2068**

Gresham-CAP's sonar-environment prediction-and-display system (SEPADS) (sonar ray-path predictor) is used specifically with surface-ship towed arrays. 2068 incorporates a library of oceanographic information on a 50-Mbyte hard disk and a series of sound-propagation loss models (each taking about 1.5 sec to run) to predict ranges and to estimate the optimum array depth. The associated computer is a commercial Digital PDP-11/44, and the prediction is updated every 4 to 6 hr.

◆ **Type 2069**

See Type 195, of which 2069 is an updated version. Reportedly, it operates at much higher power at a lower frequency.

◆ **Type 2071**

Submarine noise decoy.

◆ **Type 2072**

Submarine flank-array processor.

◆ **Type 2073**

Type 2073 is an emergency underwater telephone (rescue pinger) for submarines, made by A.B. Precision (Poole), Ltd. It incorporates a 10-kHz submarine-location pinger (effective range 8000 yd), a 10-kHz communications channel, a 37.5-kHz channel for voice communication with a DSRV, a 27-kHz channel for communication with commercial submersibles, and a 43-kHz telephone channel for diver communication. Effective range: 4000 yd at 10 kHz, 2500 yd at 27 kHz, and 750 yd at 43 kHz. Type 2073 is currently in production for the Royal Navy.

◆ **Type 2074**

This fully integrated active/passive bow-array sonar, for new nuclear attack submarines, is to replace Type 2020/2027. Plessey received the development contract in February 1988. Type 2074 is derived from Type 2054. Deliveries should begin in mid-1990; as of mid-1989, contracts had been awarded for 7 units.

◆ **Type 2075**

This hull sonar for Batch 2 *Upholder*-class diesel-electric submarines (for delivery from 1991) is to replace Type 2040. The array locations would match those of Type 2040. Tenders for this contract were invited 24 August 1987, due 25 February 1988. Ferranti was awarded the contract for this system. It has a newly designed bow cylindrical array plus a transmit array, a new passive-ranging array, new intercept-array modules around the fin (which houses a new HF scanning array [see FMS 52, below] for mine detection), a stern array, standard flank arrays, and a clip-on towed array. Six of the outboard transducers are of a new Ferranti design. Each of 5 operator consoles will have 2 color screens, a trackball, and touch-sensitive plasma panel controls. The consoles will be linked by fiber-optic cables in an LAN. Each will be able to display and control any sonar function. Processing will be by a combination of 32-bit microcomputers and parallel processors (transputers), and software will be written in ADA.

The export version of Type 2075 is FIS 3 (Ferranti Integrated Submarine Sonar Suite), announced in 1989.

Type 2075 was the first Royal Navy total-sonar-suite contract offered to a single source.

◆ **Type 2076**

This projected sonar suite for the *Swiftsure* and *Trafalgar* classes is to replace Types 2001 and 2020. Competitive project-definition contracts were to be let in 1990. The Royal Navy hopes for some degree of commonality with 2078, below.

◆ **Type 2077**

The contract for this submarine obstacle-avoidance sonar was awarded to Plessey early in September 1989; it won over the Ferranti FMS 52. Type 2077 is a high-definition LPI (low prob-

ability of intercept) sonar, probably equivalent to the U.S. MIDAS of the *Los Angeles* class. As of 1989, the Plessey system had not yet been tested as a unit. However, it uses proven arrays and components, some of the latter identical to those of the Hydra selected for Swedish submarines and to those of the British Type 2074.

◆ **Type 2078**

This integrated sonar suite is being developed for the next-generation British nuclear attack submarine, SSN 20. Bids for 2078 closed on 14 September 1989, and 2 project-definition contracts were to be awarded in the spring of 1990.

◆ **Type 2093**

Type 2093 is a replacement for Type 193. See the Mine Warfare section.

◆ **Type 2095**

Type 2095 is the generic designation for the successor for the Type 195 helicopter sonar. Cormorant (see below) may be chosen as the basis for Type 2095.

◆ **Merlin Dipping Sonar (SR 6629)**

The Cardinal Points specification for the dipping sonar for the new Merlin helicopter (the British version of the Anglo-Italian EH-101) was to have been issued in February 1988, but it was not issued until about April 1989. At that time 5 months were allowed for a response, and 7 for evaluation. AQS-903 had already been selected as the Merlin sonobuoy processor, but it was no longer clear that it would also have to process sonar data. The alternatives (as of mid-1989) were HELRAS, Cormorant, HIPAS, FLASH, and Osprey. The Italians provisionally selected HELRAS for their version of EH-101 in 1984, but as of 1989 they were not yet fully committed.

◆ **SIU**

The Sonar Interface Unit federates the existing British submarine sonar suites that were designed as combinations of discrete units. The SIU allows any console to display and process data from any of the arrays. As mounted in HMS *Turbulent*, the SIU connects Types 2007AC, 2008, 2019, 2020, and 2026. This combination is presumably a standard suite.

◆ **Aal**

This experimental surface-ship/submarine towed array is being developed by Ferranti under contract to the French navy. It is being run in parallel to the British programs (1 of the 2 competitors for which is Ferranti) defining the next-generation British towed-array sonar (see Type 2057 above). Aal will be a digital array, using outboard electronics in the array proper to digitize the analog signals from the hydrophones. They are multiplexed to run along a single link back to the ship. Both electrical and fiber-optic links are to be tested. Ferranti claims that the outboard multiplexer/digitizer substantially increases array performance and makes for substantial growth potential. Although Aal is currently an experimental program, the French navy expects to buy up to 20 of these arrays for operational use.

With the formation of the Ferranti-Thomson Sintra joint venture on 31 May 1990, this is now an Anglo-French project. However, the Aal contract was awarded prior to the formation of the joint venture, and it is, therefore, listed in the British section of this book.

◆ **AS380**

Because of its high resolution, AS380 can be used both for mine countermeasures and short-range submarine detection. UDI claims that it can detect targets out to 3000 m and classify them at ranges up to 1000 m.

One was supplied in 1986 for installation on board a Swedish navy KV-107 helicopter.

An AS380E version, with electronic beam-forming, is under

development in collaboration with Marconi Underwater Systems and Marconi Maritime Applied Research Laboratories.

◆ ATAS

Active towed-array sonar, developed by British Aerospace, consists of a flex-tensional transducer towed up to 900 m astern of a ship, with a 20-m (88-mm diameter) towed-array receiver another 300 m farther aft. Transmission is omnidirectional (in the horizontal plane), with a beamwidth of 25 deg in the horizontal. The resolution of received bearings is 0.5 deg in the broadside beam.

The array is actually 3 arrays in a single fairing, so there is a triangle of transducer at each sensor point. The system automatically selects the pair with the greatest horizontal separation at any instant and, thus, has no difficulty in avoiding the right/left ambiguity of conventional (single-line) arrays.

Operating at 3 kHz, the array is 16 wavelengths long and the transducer is 2 wavelengths high.

The entire system can be streamed from a ship of 250 tons or more, at a depth as great as 200 m. Operational speed is 5–20 kt, and the array can survive towing at 30 kt.

The transmitter requires a peak power of 25 kW and is 1.2 m high, 0.7 m long, and 0.3 m wide (weight 200 kg). Frequency is 3.5 kHz. On-board electronics weigh 280 kg, and the handling system weighs 7 metric tons. The 900-m cable is 23 mm in diameter and weighs 1.5 metric tons.

Several ATAS were reportedly procured by the U.S. Navy early in 1987 to support the development of an active surveillance towed array, presumably a future SURTASS system (see the Surveillance and Control section).

ATAS was tested in the Baltic on board the Swedish mine-sweeper *Skafo*. Thomson Sintra is now collaborating with British Aerospace in this project, supplying the signal processor and a console adapted from that of the Spherion sonar.

ATAS active transducer. (Author)

◆ COMTASS

Plessey's Compact Towed-Array Sonar System is available both for surface ships and for submarines. There are 3 versions: COMTASS 1, which gives broad-band surveillance in 3 frequency bands; COMTASS 2, which adds narrow-band surveillance and classification; and COMTASS 3, which adds automatic detection. The array is 97 or 129 m long, with a diameter of 63 mm, and is towed on a 1000- or 1500-m cable (diameter 25 mm). Total wet-end weight is 2600 kg, and overall weight is

6 tons. Plessey claims that contacts can be detected at CZ range, about 30 nm.

This system was evaluated by the Royal Swedish Navy in 1986–87 on board the corvette *Malmo*, and reportedly COMTASS will be ordered for at least 8 Swedish submarines.

The COMTASS tests in Swedish waters were reportedly less than successful (the array kinked as its tower turned to avoid underwater obstacles). As of late 1990, Marconi (which now owns the former Plessey underwater-weapons division) reportedly was less than sanguine about the prospects for small-ship arrays. It was considering changing the program to emphasize the array's ability to detect and track surface targets, e.g., in an antismuggling role.

◆ Cormorant

The development of Plessey's LF helicopter dipping sonar, the first of its kind, began as a private venture in 1978. The dipping body has now (1988) completed development and can, therefore, be incorporated into a production sonar. Cormorant has been selected for evaluation by Canada, the United Kingdom, and the United States, in the last country both under a NATO Comparative Test Program and as part of the U.S. ALFS program (see below). Cormorant is the wet end of the Canadian AQS-503 (HAPS).

The sonar body is streamlined enough to be flown while trailing below a helicopter, yet in the water Cormorant is large enough to provide useful sonar beams at low frequencies. This capability is achieved by placing the stave transducers on arms that deploy outward, like gates, from the dipped body. The arms are long enough (vertically) to provide a useful degree of beam-forming in the vertical plane. As a result, in shallow water the beam can be focused more or less horizontally and, thus, can be kept clear of both the surface and the bottom, avoiding excessive scattering and reverberation. This solution cannot substitute for a large LF transducer, but Cormorant should achieve much better ranges than current small MF types.

The transducer can operate in both the active (CW and FM-slide pulses) and passive (broad-band) modes. Power is provided by transmitter modules, each of which generates 2.2 kW.

In its ALFS form, the entire system weighs only 640 lb. It

Cormorant (PMS 122) lightweight dipping sonar, with its transducer array extended. (Plessey)

operates at 1500 ft in depth (2000-ft cable), with 3 selectable frequencies and 5 selectable pulse lengths. The streamlined body sinks at 15 ft/sec (and retracts at 25 ft/sec) so that dipping time is not excessive even at great depth. Bearing accuracy reported in 1988 was 2 deg active and 5 deg passive.

Guillemot, an enlarged Cormorant (2.5 kHz rather than the 5 kHz of Cormorant), was canceled in 1990 because the smaller Cormorant achieved the performance desired from the larger array.

◆ Crayfish

Marconi Undersea Systems's private-venture line enhancer was displayed at the RNEE show in 1989. Added to a passive sonar, Crayfish extracts coherent lines and improves their signal-to-noise ratio by 10 dB before displaying them as lines on its screen; the result should be better distinction of narrow lines (submarine tonals) amidst relatively broad-band surface-ship noise. Crayfish is a 16-channel system (i.e., it can accommodate 16 beams) using the Texas Instruments TMS 320C30 general-purpose floating-point digital signal processor.

◆ Curtis Architecture

The Curtis architecture is a more efficient approach to sonar (particularly towed array) beam-forming and signal processing, developed by Dr. Tom Curtis of the ARE and applied to sonars such as Types 2031Z and Type 2046. It represents an alternative to more conventional processors such as UYS-1 and -2. As announced in 1983, the Curtis architecture was said to have reduced processor weight by 60% and processor power by 80%.

ARE work in digital beam-forming began with the large-aperture planar array tested on board HMS *Matapan* in 1968-77. The array had numerous elements, and the beam-former and signal processor required 35 minicomputers, more than one hundred 19-in cabinets. The total memory required for beam-forming was 8.5 Mbytes, carried in more than 500,000 RAM chips. New features of this system included fully electronic beam stabilization and doppler correction within an FM pulse. The *Matapan* experiment was taken to show that future active and passive systems would need throughputs of at least 250 MOPS (million operations/sec). Although the towed arrays do not have as many elements as the *Matapan* planar (2D) array, they do approach its level of complexity.

The Curtis architecture has not been described publicly, but it seems likely that the key perception was that some calculation could be avoided if, given the magnitude of the quantities involved, the results could not be particularly significant. For example, in theory, the output of every element of an array contributes to some extent to each beam. However, if the output of an element that would normally make a small contribution were itself quite small, then it may be neglected altogether and not carried forward. That in turn would eliminate later sets of calculations involving the neglected item. Such an architecture does not treat all data equally (i.e., in parallel) and, thus, requires the one published feature of the Curtis Scheme, tag-driven signal flow (each digital sample, i.e., each data point, is tagged to determine its future processing).

The ARE processors use a combination of special LSI chips and software developed for the U.S. UYS-1. The resulting modules, Control Ordered Sonar Hardware (COSH), can be combined in distributed networks to produce complete systems with throughputs of 100-300 MOPS, about 10 times that of the U.S. UYS-1. Type 2031Z uses a 250-MOPS version, and 2 twin-screen (2-operator) displays plus 1 air-cooled processing cabinet and a hard-copy printer. ARE describes the COSH modules as hardware equivalents of software macros. An executive (software) program calls up the modules in the appropriate order, a method equivalent to that of a relatively simple program using subroutines (macros).

One of the first Curtis processors was first tested on board HMS *Lowestoft*, at that time equipped with a development version (IX) of 2031I, in October 1981. As a result of these trials,

2031I was dropped in favor of 2031Z; and the next-generation surface-ship towed array, 2038, was abandoned. The test version, Type 2031Y, was installed on board HMS *Arethusa*. At £600,000, Type 2031Z cost only slightly over a quarter as much as 2031I. The other major current application of COSH technology is 2046. In that case, ARE developed the beam-former and signal processor, and Ferranti, the prime contractor, was responsible for display processing. Type 2046 uses the same terminal unit and some of the same beam-former circuit boards as 2031Z. During the Falklands War, ARE applied COSH technology on an urgent basis to augment the conventional signal processor of the nuclear submarines' Type 2024, delivering units in quantity within 6 weeks.

The current COSH LSI-technology circuit board has a throughput of 10 MOPS, approximately equivalent, reportedly, to that of the U.S. UYS-1. The 2031Z processor has a total volume of 4 m³ and weighs 2500 lb. The U.S. SQR-19/UYS-1 has a floor area of 4.65 m² and a dry-end weight of 12,900 lb. Using newer technology, ARE has been able to package a 5-octave processor in a 50-lb desktop box (ARE T56), using an IBM PC-compatible host processor. Throughput is over 250 MOPS.

Current (1989) efforts exploit the rapid improvement of electronic hardware; ARE estimates that packing density doubles every 2 yr, and that an entirely new chip technology appears every 5 yr. For example, the 4-Mbit memory chip of 1987 was a 20 million-fold increase in complexity compared to the first integrated circuits of the mid 1950s. Greater computing power can be used both for more intensive exploitation of existing arrays and also to allow for more complex future arrays (with many more elements), such as conformal ones. Longer single-line arrays will show appreciable bending, and the beam-formers will have to take their changing shapes into account. Beam-forming algorithms are being modified for a 3-4-fold improvement in bearing accuracy, the ultimate limit (set by the number of elements in the array) being a few tenths of a degree. The more powerful memory chips also make for an updated display. The current ARE desktop machines use 64k memory chips, and as of late 1989, 1-Mbit memory chips were available.

The 2 desktop machines demonstrated so far are T26 (150 MOPS), sufficient for a 2-octave towed array, and T56 (250 MOPS), for a 5-octave array. The latter is more capable than 2031Z but costs only £12,000 in a commercial-standard version (ARE estimates that a militarized version would probably cost £40,000). T56 uses a high-resolution (1536 pixel × 1280 line) monochrome display. In 1989 ARE expected future sonars (2057 and 2078) to require 3 orders of magnitude more processing power, i.e., teraflops (million million operations per second).

The new electronics should be able to cope. As of 1989, ARE had designed a 32-bit Complex Vector Processor (CVP) on a 300,000-transistor chip. Two such chips are equivalent to a complete T6-series circuit board (but operate at 10 times the speed); a complete card could have a throughput of 1400 MOPS. Such a board should be able to execute a 1024-point complex FFT in 41 microsec.

◆ Dolphin 1000-Series

Marconi's sonar processors, both broad- and narrow-band, are to upgrade submarines' existing arrays or to be installed as part of the systems of new-construction submarines.

There are 4 main processors: a broad-band processor fed by either conformal or cylindrical arrays; a broad-band line processor; a signal analyzer; and an intercept processor. The broad-band processor provides HF or LF waterfall displays (time vs. bearing, with up to 20 min shown). Several targets can be autotracked simultaneously. The broad-band line processor, which can take signals from flank, bow, or towed array, displays either the combination of these signals or else the output of separate arrays. The analyzer provides spectral data and can also apply DEMON to retrieve spectral data from broad-band noise. The intercept processor provides bearing, time, pulse parameters, and a list of intercepts.

◆ Ferranti Modular Sonars (FMS-Series)

The FMS-series was announced at RNEE 1983, and trials of the first type, FMS 12, were conducted in 1984. There are 6 series, plus a vibration-monitoring system (VIMOS):

FMS 10 Surveillance and classification (narrow-band processing) for towed or flank arrays.

FMS 20 Search and attack (active) sonars: FMS 20 (for corvette/frigate) and FMS 21 (the export version of Type 2050, for frigate/destroyer). Both use Argus M700 processors, both use FM and CW pulses, and both have passive broad-band and narrow-band capabilities for torpedo detection (torpedo alarm). Each displays target tracks and a track-history tote (alphanumeric display), and each can automatically track 40 targets simultaneously. Each also incorporates a ray-trace predictor. FMS 20 uses a 4-ft-diameter transducer with 32 preformed beams; FMS 21 uses a 6-ft transducer with 64 preformed beams. The hull arrays can be bow- or keel-mounted, and there are associated VDS designs.

FMS 30 Broad-band passive sonars. FMS 30 has a 3-ft array, and there is also an FMS 31.

FMS 40 Active intercept sonar.

FMS 50 HF active sonar (obstacle avoidance, minehunting). See FMS 52, below, and also the FMS 58 minehunting sonar.

FMS 60 Passive-ranging sonar.

◆ Ferranti FMS 12

This 2-octave narrow-band passive-sonar processor was chosen as part of the Triton (Type 2051) program (*Oberon*-class update) in 1985, to work with flank and towed arrays. The digital signal processor embodies the new Curtis architecture (see Type 2031). The reported frequency range is 10–384 Hz and 384–768 Hz. The system operates on 32 preformed beams. There is a simple multiple-beam (waterfall) display for surveillance, and a high-resolution vernier (frequency) display for classification. Self-noise can be processed out. Optional improvements are automatic target detection and classification, automatic communication with a submarine's tactical system, hard copy output, and a color display.

FMS 12 is the basis of Type 2051.

◆ FMS 13

FMS 13 is a 3-octave narrow-band passive signal processor. Both this and FMS 15 (below) use Argus M700 microprocessors and transputers for signal processing; both are capable of auto-tracking. FMS 13 is intended for submarines (the more powerful FMS 15 is intended for surface ships, which have longer arrays and, therefore, can make use of a broader total frequency range).

Although these are primarily processors, the FMS designation includes a towed-array wet end. FMS 13 is the basis of Type 2046.

◆ FMS 15

FMS 15 is a 5-octave narrow-band passive signal processor, using 32 preformed beams. Like the simpler FMS 12, FMS 15 provides both a multiple-beam waterfall display and a high-resolution (very narrow band) classification display. There is 1 operator console with 2 side-by-side screens. FMS 15/2 was ordered by the Royal New Zealand Navy for *Leander*-class updates in 1989 (for delivery in 1991). FMS 15 (8 sets) has also been sold to Korea, presumably for the new submarines.

◆ FMS 52/TG 3

This short-range, dual-frequency, high-definition sonar, for submarines, harbor surveillance, or surface ships, was announced in 1989. It had just lost out to the Plessey alternative in the Type 2077 competition. However, a version has been supplied to the German navy for the new Type 212 submarine, and FMS 52 technology is incorporated in the mine avoidance element of Type 2075. FMS 52 was itself derived from an unspecified

Royal Navy sonar, an outgrowth of TG 1, a high-definition sonar developed by the Ferranti subsidiary, USL. TG 3 is a scaled-down version of FMS 52 for ROV application, particularly in the Ferranti Integrated Mine Countermeasures System (FIMS). FMS 52 can be fin- or hull-mounted on a submarine, and it can be combined with hull-mounted side-scanning arrays derived from the Dowty 3010 (which Dowty claims can be used for under-ice topography).

Beams are electronically formed and steerable; bearing resolution is 3 deg. Each array covers up to 90 deg.

FMS 52 has been sold to both Germany (12 sets for submarines) and Korea (8 sets, probably also for submarines).

◆ GETAS

Marconi's passive towed array uses a wet end from Geophysical Company of Norway (GECO A/S). Versions for both surface ships and submarines are available, and the array can also be laid on the bottom for surveillance. GETAS is being tested for 6 months on board a Norwegian submarine; it may become part of the standard Norwegian submarine sonar suite.

◆ Plessey PMS 26/27

Sector-scanning sonars (ODT), for medium and small ships, these units are closely related to the Type 195 helicopter dipping sonar. They cover 360 deg in 4 steps and can depress their beams for MCC. The transducer is 44.5 cm wide × 99.6 cm high × 53 cm deep and weighs 100 kg. Theoretical range is 7.5 km, but effective range is about 4.5 km. PMS 26 is in a retractable dome.

MUSL (the successor to Plessey Naval Systems) currently markets a solid-state replacement called PMS 26/27 Mod 1. Operating frequencies are 9.5, 10, and 10.5 kHz; pulse widths are 250 msec and 1 sec (modes FM and CW). Range scales are 3, 6, 12, and 18 kyd. There are 4 operating modes: (i) active, (ii) active doppler, (iii) short CW pulses for short range (presumably, in addition to the pulse widths listed above), and (iv) passive. Options include passive tracking, operating at 20 kHz, an underwater-telephone mode, and an automatic interface to a CDS.

PMS 26 was marketed as a replacement for Type 164/174, which were often used in combination with a Limbo control set (170). Although PMS 26 has a maintenance-of-close-contact (MCC) feature (i.e., beam depression), it is unlikely that this sonar in itself can track in 3D or can be used to control Limbo directly. Therefore, it seems likely that Type 170 survives in ships refitted with the new set. Of 55 PMS 26s sold, 42 or 43 were reported still in service in 1987. Buyers: Denmark (*Peder Skram*- and *Nils Juel*-class frigates, fishery-protection ship *Beskæterren*, *Daphne*-class ASW craft), India (probably on board *Blackwood*-class frigates, now discarded), Indonesia (probably ex-Tribal-class frigates), Iran (destroyer *Damavand* and probably 4 Vosper Mk 5 frigates), Ireland (*Eithne* [PMS 26L]), Malaysia (probably frigates *Rahmat* and *Hang Tuah*), Mexico (probably 2, applications unknown), Nigeria (*Obuma* and Vosper Mk 3 and Mk 9 frigates), Portugal (probably the frigate *Pedro Escobar*, now discarded), Turkey (patrol boat *Girne* and probably also AB 25 class), Venezuela (probably refitted *Nueva Esparta*-class destroyers [now discarded], and 2 *Almirante Clemente*-class corvettes).

PMS 27 is the same sonar using a different hull outfit suited to ships down to 750 tons.

◆ Plessey PMS 40 Series

A new private-venture hull-sonar series, PMS 40 was announced in 1983. There are 3 versions, PMS 42, PMS 44, and PMS 46, to cover the full range of ship sizes, from patrol craft up through destroyers. PMS 42 employs a single electronics cabinet and a 27-in (diameter) transducer; PMS 44 has 2 cabinets and a 44-in transducer (corvettes and above); PMS 46 has 3 cabinets and a 78-in transducer.

These sonars are extensively automated to reduce manning, each having only a single operator. Multiple transmitting elements provide redundancy. Presumably, that redundancy means

that much of the transmitting function is concentrated in the individual staves, rather than in a centralized power source. The operator selects such pulse transmission characteristics as long/short mode (which can be interleaved) and frequency. It appears that the primary operating modes are ODT and passive, and for larger ships the beam itself can be electronically stabilized.

Simultaneous computer-aided tracking is provided for up to 10 active contacts, and there is an automatic torpedo alarm. A scanning audio channel locks onto the sources of such alarms to assist in classifying them.

PMS 46 is on board the Danish fishery protection frigates of the *Hvidbjørnen* class.

◆ Plessey PMS 56

MUSL is currently (1991) marketing this modified Cormorant as a replacement for PMS 26. Cormorant uses a series of vertical arrays of receivers with the omnidirectional transmitter below them. In PMS 26 the vertical arrays of receivers form an arc (a volumetric array) forward of the transmitter. Each vertical array carries 6 small transducers, as in Cormorant; the arrays are arranged in fore-and-aft lines (4 arrays per line), and there are 6 such lines, for a total of 24. Presumably, the operating frequency matches that of Cormorant, reportedly about 5 kHz. As in PMS 26, the system is designed for a single operator, in this case using on-screen menus to change from mode to mode. The display is a high-resolution color CRT. The operating modes are FM, CW, passive, and aural; pulse lengths are 5–1000 msec; range scales are 625–20,000 yd. Display formats are surveillance (pulse) and doppler. PMS 56 can use existing sonar domes, so, presumably, it is not too much larger than its predecessor. MUSL offers its own fixed or retractable dome as an alternative for new construction. Because it was adapted from a helicopter sonar, PMS 56 is quite small; inboard processing and display electronics weigh 120 kg altogether (with another 50 kg for the transmitter), and the hull outfit (dome) and array weigh a total of 385 kg. As in Cormorant, PMS 56 is a digital (DIMUS) sonar, sufficiently precise to support attack by lightweight torpedoes (MUSL advertises it in combination with PMW 49a, its torpedo launching system, and, presumably, Stingray torpedoes). The beams depress to maintain close contact.

In fixed-dome form this sonar is suited to ships of up to 3000 tons (speeds up to 30 kt); there is an alternative version with a retractable dome, for ships up to 1000 tons (18 kt with dome extended, 30 with dome retracted). Existing PMS 26/27 sonars can also be updated to PMS 56 standards.

PMS 56 is part of a new Hydra-series of modular sonars, some of which equip the Swedish *Sjöormen*-class submarines.

◆ Plessey Hydra

Hydra is a family of sonars using common hardware: arrays, beam-formers/signal processors, data processors, and displays, all linked by data bus. The options are:

(i) Arrays:

- Dunker (adapted helicopter LF dipping sonar)
- Lightweight Active (omnidirectional LF pinger with helicopter-type receiving staves)
- Variable Depth
- Flank
- Lightweight Passive (planar array)
- Passive (cylindrical)
- Active/Passive (cylindrical)
- Conformal
- Towed

(ii) Beam-Formers/Signal Processors

- Cabinet
- Single Shelf (in standard electronic enclosure)

Options are broad- and narrow-band, active, DEMON, aural, sonar intercept, passive ranging, mine avoidance, and underwater communications.

(iii) Data Processing

(iv) Man-Machine Interface

As examples of installations, Plessey shows a missile destroyer (similar to a British Type 42), a nuclear submarine, a diesel submarine (e.g., a Swedish unit), a midget submarine, and a patrol boat based on a *Sandown*-class minehunter hull. Each shows different Hydra elements.

The destroyer has a hull or bow array with 2 processing cabinets and a 3-operator suite of consoles.

The nuclear submarine has a large bow conformal array, an intercept array, a flank array, a mine-avoidance array (in her sail), and a towed array. It requires 10 processing cabinets (2 per array) and a 5-operator console suite.

The diesel-electric submarine has only the bow conformal array and the flank array. It has 2 shelves of processing electronics supporting a 2-operator console suite.

The midget has only a lightweight passive array (in the bow) feeding a single processing shelf and a monitor display (rather than a full-height console).

The patrol vessel has a lightweight hull active array, a dunking array, and a VDS. It uses 4 shelves of processing electronics feeding a single-monitor display.

The only announced customer is the Royal Swedish Navy: the *Sjöormen* and *Västergötland* classes are both to refit with Plessey Hydra towed arrays (129-m [423-ft] array on 457-m [1500-ft] cable) and improved hull sensors.

◆ Plessey Fiber-Optic Hydrophones

Plessey has been developing fiber-optic hydrophone arrays since about 1979. A sound wave hitting the hydrophone distorts it and thus changes the length of the optical fiber wrapped around it. Plessey claims a proprietary pulsed reflectometric interferometric technique, which multiplexes up to 50 sensors onto a single fiber driven by a single laser. Probably the laser pulse is split by being partially reflected at each sensor; that way the length distortion in each sensor can be measured separately. The array can be as much as 30 km from the laser, and sensors can be 1 m to 1 km apart. The sensor, which is 5 × 18 cm, responds equally well to signals of 5 Hz–4 kHz. Plessey advertises the optical array for seabed barriers or phased arrays and also for towed and outboard arrays.

◆ Plessey Flank Array

This submarine sonar was announced in 1989. It consists of standard modules (2.0 m long, 1.2 m high) each containing up to 12 Plessey patented large-area hydrophones embedded in a special resin fairing. Frequency range is 10 Hz–6 kHz, the upper frequency depending on beam-forming electronics and array spacing. Each hydrophone incorporates its own preamplifier and, thus, can be connected to a long cable array without loss of performance.

◆ Sea Hunter

This Graseby 10.5-kHz sonar intended for craft of over 150 tons was announced at RNEE 1989. The transducer (500-mm diameter, 560 mm high) is a lightweight 24-stave cylindrical array, and the display is a color CRT. Transmission modes are ODT and random rippled directional (RRDT), with pulse lengths of 20, 40, and 100 msec, FM modulation, and a source level of 220 dB (re 1 microPascal at 1 m). There are 12 receiver channels (i.e., beamwidth is 30 deg). Range scales are 2, 4, 8, and 16 kyd or km. Sea Hunter can auto-track up to 4 targets and can display a 5-ping history of each. Targets can also be manually tracked. Range accuracy is 1%, and bearing accuracy is within 1 deg, presumably achieved by beam switching. Sea Hunter operates over a 1-kHz audio band in passive mode, and the display incorporates an audio cursor for search and classification. The installation consists of a single display cabinet, 2 electronics cabinets, and the transducer.

◆ Sea Searcher

This new 6–9 kHz Graseby sonar was first shown at RNEE 1989. It is intended for ships of over 1500 tons and is presumably conceived as a replacement for sonars in the Type 184 class (Graseby also offers a modernization kit for Type 184). Sea Searcher uses a cylindrical 32-stave transducer. Pulse lengths are 20, 40, and 100 msec, and transmission modes are ODT and RRDT; pulse forms are FM and shaped CW. Range scales are 5, 10, 20, and 40 kyd or km. The PPI display shows 16 channels (beamwidth 22.5 deg). Up to 4 targets can be auto-tracked. Range and bearing accuracy are 1% and 1 deg, respectively. Doppler processing can handle speeds of up to 40 kt with a resolution of better than 2 kt. In passive mode the sonar has both video and audio channels. The installation consists of 7 electronic cabinets (which include the display) plus the transducer. The color CRT shows 2 or 3 alternative geographically stabilized displays, including multiple histories for all targets of interest, and speed and course of selected targets are read out numerically.

◆ Smiths Industries Hi-Scan Sonar

This high-definition scanning sonar is primarily for remotely controlled vehicles. The sonar operates at 300 kHz (600 kHz in production sonars). It transmits at HF and scans very rapidly over a limited sector to receive. The beam (2 deg wide) is scanned electronically over a 30-deg sector; range resolution is 7.5 cm. Vertical beamwidth is 7 deg, and the transducer can tilt through 90 deg. In the 600-kHz version, beam dimensions are 1.6×10 deg (but claimed resolution is better than 1 deg), the beam scanning at 15 kHz and using a 75–400 microsec pulse (source level 214 dB); PRF is 4, 8, 16, or 32 kHz. Range resolution is 5 cm. Instrumented ranges are 5, 10, 20, 40, 80, and 160 m. The transducer is a 16-element receiving array and projector, $120 \times 45 \times 60$ mm (2 kg). The display is a standard 16-color television monitor (raster scan), display information being held in a frame store and updated on a frame-by-frame basis. This scheme avoids flicker and, thus, makes the display easier to view.

Smiths Industries Hi-Scan 600 was developed to meet an MoD requirement for a mine-clearance sonar for remotely controlled underwater vehicles.

◆ SP2110

SP2110 is a GEC Avionics towed small-ship export array based on Type 2031 I and Type 2026 technology. The manufacturer claims that SP2110 will be less expensive than those earlier systems and that its modular design makes for relatively simple expansion. Basic options include DEMON (i.e., extraction of LF spectra from higher-frequency signals); narrow-band surveillance, classification, and tracking; and broad-band surveillance. Autodetection and autotracking can be provided. This system was announced in 1988.

◆ SWS 35/40

This streamer array sonar for small boats is made by Ameeco Hydrosience. The wet end is 92 mm long, carrying clustered hydrophones operating in the 25–3200-Hz range, plus 2 HF hydrophones. The array is towed on a 150-m cable. The processor forms broad-band beams using the hydrophones; and the 2 HF hydrophones (which are intended as sonar-intercept receivers, primarily against high-definition navigational sonars) have a separate display.

SWS 40 adds a vertical array that can be steered to exclude surface reflections. The vertical array produces 5 beams, over a broad frequency range (7 octaves).

Ameeco also makes a seabed horizontal array, SWS 45, intended primarily to protect offshore oil rigs. Early in 1989 it was reported that Ameeco was developing an experimental Royal Navy array using fiber optics both for data transmission and for the hydrophones proper. In theory, a fiber-optic hydrophone would detect sound by measuring the change in the length of

an optical fiber wrapped around a deformable body. The phase of a light signal sent through this fiber would vary as it stretched or contracted. This same signal could be amplified and sent back up the information-transmission cable. In theory, such information might be much less subject to electrical noise than the usual electrical signals. In addition, optical fibers should be able to carry vastly more data than conventional cables. Advances in optical computers, which are particularly well adapted to the sort of parallel processing required for ASW, might make an optical array particularly attractive. Ameeco is not alone in working on optical hydrophones, but no other projects have become public.

◆ Swimmer Detection Sonar

Plessey announced this harbor- and oil-rig-defense device at RNEE 1989. This version of the company's mirror sonar (described in greater detail in the Mine Warfare section) automatically detects both swimmers and swimmer-delivery vehicles, maintains a target velocity and track record, and provides programmable alarm levels. The sonar operates at 100 kHz and has a 1.3-deg beam scanned electronically over 40 deg (mobile installation) or 120 deg (fixed installation).

◆ Ulvertech ROV Sonars (Models 3025 and 3030)

These 2 ROV sonars, both of which use software-controlled electronic beam-forming, have been bought by the British MoD. Model 3025 is a search sonar; Model 3030 is a high-resolution target sonar (HRTS). In each, the sonar transmits over a sector, and the received signal is broken into 8 preformed beams. The transducer head moves to change sectors. Because the beam automatically scans over all 8 beams simultaneously, scanning can be much faster (the manufacturer claims 10 times faster) than for a single-beam sonar.

Model 3025 transmits at 110 kHz using a 25×12 -deg beam; the receiver breaks the reflected beam into eight 3-deg beams. Scan rate varies over 30–170 deg/sec depending on mode and range (35, 50, 100, 150, 200, 300, 400, 500 m or yd). The display is a 512×512 -pixel CRT with 16 shades of gray or color. Minimum range is 1 m, and a magnification setting gives a range resolution of 170 mm. The scanning sonar head is $250 \times 250 \times 330$ mm (20 kg). The operator controls sector width (in multiples of 25 deg) and position, display gain, transmission power, pulse length, and sonar gain.

The high-resolution Model 3030 operates at 580 kHz, forming a 5 or 10×35 deg (extending between $+5/-30$ deg) beam for transmission and eight 0.7- or 1.25-deg receiving beams. Scan rate varies over 30–170 deg/sec depending on mode and range (10, 20, 30, 40, 50, 75, 125 m or yd) selected; minimum pulse length is 50 microsec. The display is similar to that used by Model 3025. Scanning head dimensions are $230 \times 230 \times 180$ mm (13.3 kg). Target classification is achieved by the combination of a very narrow beam and a very wide dynamic range so that target highlights and shadows are visible (i.e., the 16 gray scales on the CRT).

◆ Plessey Block Floating-Point-Arithmetic Unit (BFPAU)

In April 1989 Plessey announced a new microchip specifically designed for signal processing; it is the first fruit of a British VHPIC (Very High Performance Integrated Circuit) Applications Demonstration Program. Plessey is to demonstrate the chip in two 1989 applications, a towed-array processor and an in-buoy preprocessor. In the latter application, buoys would process, filter, and distribute data autonomously, burst-transmitting to a patrolling airplane. Each buoy would use a single buoy; the surface-ship processor uses several.

The chip consists of 2 arithmetic elements and a sequencer. Each of the arithmetic elements consists of three 16-bit input registers, a 24-bit multiplier, a 48-bit accumulator, a 48-bit up-shifter, 2 rounders, a 26-bit ALU, and a 26-bit down-shifter. The 2 arithmetic elements are mounted back to back so that they can exchange data readily. The sequencer contains 128 instructions, but all need not be in the same program. It is fed with

instructions giving the initial, restart, and final steps, and also the number of loops to be executed. Plessey claims that its chip can execute 24-bit floating-point arithmetic 10 times faster than current signal processors. It incorporates a special RISC instruction set and can achieve 200 MOPS (1 GOP on a full 100 × 70-mm computer card) using 240,000 devices (1.4 micron CMOS technology). The chip itself measures 1.1 cm². The ultimate goal is 10 GOPS, a factor of 50 improvement. A typical current British sonar processor operates at 100 MOPS.

BFAU is 1 of 2 chips being developed in a joint MoD/Plessey program, financed on a 50-50 basis. The other chip, the Table Memory and Address Modifier (TMAAM), is intended to control the BFAU, scheduling data flow between RAM and the arithmetic chip. TMAAM also contains tables of transcendental functions, and it controls exponents within BFAU. Together with standard memory chips the 2 new ones will constitute a high-performance signal processor.

BFAU was designed for particularly fast beam-forming, on the grounds that beam-forming is typically 50% of the processing load of a sonar-signal processor. It is designed to implement the Curtis architecture. When design began early in 1987, it seemed that 24-bit fixed-point arithmetic would provide sufficient accuracy, but that floating-point arithmetic would make for simpler system control. The compromise solution was block floating-point arithmetic (24-bit mantissa, 8-bit exponent), which is faster than pure floating point.

Plessey also produces a series of signal-processing computer cards: a vector processor, an I/O processor, an 80386 processor, and a high-integration video generator. For example, the cards can be assembled into a spectrum analyzer accepting 48 analog inputs and processing 48 channels at up to 16-kHz bandwidth using 4k FFTs (8 selectable input bandwidths in octave steps). Integration times could vary between 1.5 and 50 sec. The video processor is based on an Intel 82786 coprocessor graphic processor chip. Each can create up to 25,000 characters/sec and can draw geometric forms at 2.5 million pixels/sec (8 bits/pixel). Two chips give a 50-MHz pixel rate. Each chip has 4 Mbytes of display memory.

UNDERWATER FIRE-CONTROL SYSTEMS

◆ TCSS 9/TDHS (DCA)

Torpedo control system (submarine)/tactical data-handling system is installed in HMS *Splendid* and later British nuclear attack submarines (DCA is the designation of the tactical data system). TCSS 9 was the first (1973) fully computerized British submarine AIO. It could manage 25 tracks simultaneously, carrying out TMA on all of them to present tactical officers with a full passive picture of nearby contacts. The displays are a pair of consoles flanking the central sonar PPI, each with a twin CRT (with light pens for operator interaction). The single Ferranti FM 1600B computer is used for TMA on 24 targets, a great improvement over manual methods that (even with a large attack team) were limited to 2 or 3 targets (and which even then took considerable time).

TCSS 9 is being phased out of service. It was originally conceived as an FCS for submarines, upgraded with a torpedo-control unit Mk 2 to control Mk 24 (Tigerfish) torpedoes. In this case the computer was used only to display target and weapons information. TDHS represented the fusion of fire control and AIO functions, the computer being used also for TMA, and the automated AIO being connected to the torpedo fire-control device.

DCA first went to sea in 1973 on board HMS *Swiftsure*.

◆ DCB

The automated submarine AIO (1978) succeeds DCA/TCSS 9, requiring fewer operators. The usual command team for a TCSS 9 submarine is 13, reduced to 8 for DCB. This system is based on 2 Ferranti FM 1600B computers. DCB has 5 displays in the submarine command center, showing waterfalls (broad-band) and LOFARgrams (narrow-band). Computer fire-control solu-

tions are displayed on 2 CRTs at the fire-control console. Weapons settings are shown in tabular form, and wire-guided torpedo feedback (tell-backs) are displayed. Dowty was prime contractor.

DCB was originally designed for the *Swiftsure* class. DCB can engage 2 targets simultaneously and can track 20. It is currently being upgraded through installation of a peripheral processor, the Gresham-CAP DCG (see below). This addition enlarges DCB's memory to 128 kbytes. There have also been considerable software improvements, reportedly 5 in the last 3 yr. DCB was originally developed to fire wire-guided torpedoes as well as air-flight missiles (single-shot or salvo); Gresham Lion is now updating DCB to fire Spearfish.

In September 1990 Ferranti was awarded a contract for F2420 computers to replace the FM1600Bs of existing DCBs. Installation requires 22 days and can be carried out during a normal maintenance period; some new peripheral devices are also added. Ferranti describes F2420 as having 6 times the processing power and 8 times the memory capacity of FM1600B.

DCB employs a 2-position AIO console and a 2-position FCS console. Each position has 2 CRTs, 1 for graphics, the other for alphanumeric. Operators interact with the system mainly through light pens. There is also an automatic contact-evaluation plotter (ACEP). DCB is essentially DCA plus an extra computer for the integrated FCS.

DCB equips all British nuclear submarines other than HMS *Swiftsure*.

◆ DCC

DCC is the automated command/control system of the British *Upholder*-class attack submarine, developed by Ferranti (with Dowty-CAP as subcontractors for consoles and fore-end hardware). Two FM 1600E computers drive the 3 consoles (1 on standby). Each of the 3 equivalent operator positions can be used for either command/control or fire control. Each console contains two 12-in circular cursive CRTs, with light pens for input. KAFS (see below) has a single 2-operator (4-CRT) console and a single FM 1600E computer, for both AIO and FCS functions. It is an export derivative of DCC, with considerable commonality with other Ferranti AIO systems. KAFS can conduct automatic TMA simultaneously on up to 35 tracks. Interaction is via light pen and keyboard, and the tactical picture can be presented either as a PPI or as a vertical display. Two or more wire-guided torpedoes can be controlled simultaneously against 2 targets. A special navigational program can be run for minelaying.

COMKAFS (DCH) (see below) is a variant, used in the RN to update existing *Oberon*-class submarines. COMKAFS is built around the Argus Compact computer.

DCC(BN) is the tactical data-handling system for British Trident submarines.

◆ DCG

An add-on processor for DCB, made by Gresham-CAP, DCG is the designation for the new Dowty-Sema SMCS and is a PDP 11/44 with an array processor intended to improve TMA capability. However, DCG is also used for simulation (for on-board training), for environmental analysis (e.g., sonar ray-path prediction), and as a command tactical aid.

Computer capacity is about 8 MFlops. The array processor is supplemented by a general purpose minicomputer to organize data and control associated devices; the latter include a high-resolution color printer. DCG incorporates a fast mass-memory to hold sonar data for long-term analysis.

◆ DCH

DCH is a replacement for TCSS 10/11 in the British *Oberon* class (Ferranti COMKAFS D). The first of 12 was delivered in 1987. DCH employs the Military Argus Compact (MAC) computer, which uses the M700-series microprocessor. It is a central-computer system using 3 multifunction, multiple high-resolution video consoles (which can be color rasters). Each console can provide weapons-control data such as target designa-

tion, weapons and tube status, weapons launch, and mid-course guidance. System options include the capability to guide more than 2 torpedoes simultaneously, an automatic plotting table, and an automatic contact-evaluation plot.

DCH was formally accepted in 1989, work having begun less than 4 yr before. In April 1990 HMS *Opossum*, the first British submarine to be fitted with the combination of DCH and the 2051 sonar, completed successful tests, including the first-ever salvo launch of wire-guided Tigerfish Mk 2 torpedoes from an *Oberon*-class submarine.

◆ SMCS

Gresham-CAP's Submarine Multiscreen Command System is to replace the existing DCB/DCC on board all future British submarines (SSN, SSK, SSBN). It uses a dual-redundant fiber-optic data bus connecting 3 or 4 multifunction consoles, a main tactical display, 2 sensor-input nodes, 2 common-service nodes, and 2 remote terminals. SMCS is a fully integrated submarine-control system, the same computers being used both for information processing and for weapons control. All consoles are identical, and all are software-configured, for maximum redundancy and flexibility. For example, in 1 role all the consoles may be devoted to sonar data; at periscope depth 1 or more may display ESM data; in another role, 1 or more may function as fire control or countermeasures consoles. SMCS is a federated system using 11 computers incorporating 80386 processors plus Transputers for parallel processing. They are linked by a high-capacity (166-Mbits/sec) fiber-optic data bus. Each fiber-optic link is duplicated; when a failure occurs, the stream of data is automatically rerouted to the intact link (the system is called self-healing). The entire system is programmed in ADA (except for OCCAM, used for parallel processing). It is intended to be able to process data not only from current sensors but also from future ones such as very long towed arrays (with many more elements than at present) and optronic periscopes. Each console incorporates a graphics input tablet and a programmable keyboard.

SMCS is the first announced dedicated military application of the Transputer, and the first naval use of the new ADA language. Gresham-CAP claims that SMCS has more than 20 times the processing power of previous conventional submarine combat systems, at lower acquisition and ownership costs (and with better than 99.9% projected availability). This sort of improvement is probably a natural and virtually universal consequence of recent developments in computer hardware, paralleling well-known civilian experience.

The common-service nodes store bulk information and carry out high-speed computation (each has 8 processing cards, each carrying 8 Transputers, for a net throughput of 50 MFLOPS).

The original specification called for a service life of 30 yr. SMCS is unusual in that it is delivered to the yard packed in containers (presumably on pallets) ready for unit installation.

Development of SMCS began with the award of a contract in December 1986 after a 3-yr competition. The first kit, for installation on board the lead Trident submarine, HMS *Vanguard*, was delivered to the Trident Tactical Weapon System Shore Development Facility (SDF) at VSEL Barrow, and completed its Part 1 Naval Weapon Harbour Trial in mid-1990 (the ship will commission in 1992). The second SMCS is to be installed as a shore trainer at Faslane. The 4-console version is to be installed on board the new *Vanguards* as well as the existing nuclear attack submarines (the oldest, however, will not be refitted with it). Presumably, it will also equip the next-generation "W" class. A 3-console version will replace DCC on board the *Upholders*. Surviving *Oberons* will not be refitted.

◆ FISCS

FISCS is the Ferranti Integrated Submarine Combat System, developed primarily for export. There is a single 6-operator console, all operator positions being identical and interchangeable.

Two wire-guided torpedoes or 2 missiles can be fired simultaneously at 1 or 2 targets; the system can be expanded to control 6 torpedoes or 4 missiles. FISCS provides sonar performance prediction and is linked directly to the submarine's bathythermograph. Oceanographic analysis is possible because the system can store so much background data.

◆ KAFS/COMKAFS

Ferranti's submarine action information and FCS was announced in 1981. KAFS stands for SSK AIO and Fire-control System, and COMKAFS is compact KAFS. KAFS was first ordered to equip Brazilian Type 209 submarines. Derived from the AIO designed for the British *Upholder* class, KAFS uses a single Ferranti FM 1600E computer (192k expandable to 256k). The prototype KAFS (1982) was a cannibalized WSA-420 surface-ship AIO/FCS console. COMKAFS D will replace TCSS 9 in the *Oberon* class.

This system was designed to handle 35 target tracks (expandable to 50), performing TMA on all of them. KAFS has 2 operator positions, the computer fitting into the bottom of the console. Each position carries 2 CRTs, a tactical display on the left and a tote (alphanumerics) display on the right; only 1 display is operated in the patrol condition. The displays are canted rather than upright so that the lengthy use of light pens will be less fatiguing.

The tactical display can switch between PPI, time-bearing (waterfall), and vertical display formats, with tactical aids including calculated CPA, rendezvous, estimated time of arrival, and angle on the bow. The tote provides 37 pages of material, including weapons-control data. The operator calls up pages by applying the light pen to a menu at the bottom of the page, and also uses the pen to designate tracks to fire control. Although most commands are made by software, some critical ones, such as the firing command, are made by special buttons and switches on the control panel.

KAFS can control 4 wire-guided torpedoes firing at 4 separate targets, and it can also fire unguided torpedoes or lay mines. In addition, the system can preheat up to 12 stowed battery-driven weapons simultaneously, monitoring their condition so that they can be loaded and fired more quickly.

◆ Series 4

The Plessey Marine combat/integrated sonar systems were announced in 1986; the name reflects the use of fourth-generation, i.e., distributed, computer architecture and data busing. Plessey claims that by using high-capacity memories and fast processors, it can radically reduce the number of different components in a typical sonar system. For example, a complete sonar suite might be built up from 10 types of electronic cards (such as a 32-bit processor and an 8-Mbyte memory), compared to about 300 different cards in Type 2020. The first Series 4 suite was Pisces 4, offered unsuccessfully for the Royal Australian Navy's new submarine.

◆ TIOS

Tactical Information Organization, Submarine, by Ferranti/Vickers/Gresham-Lion, was developed in parallel with DCB and exported to Brazil (for *Oberons*) and to Israel (for the 3 Vickers 540s). TIOS was an early example of the use of a digital fire-control computer for some AIO tasks, such as TMA, applied to 1 or 2 targets.

TIOS-B is fitted to Brazilian *Oberons*. It is based on the Ferranti FM 1600B.

TIOS-C is for IKL 500/1000-ton submarines, based on the Ferranti FM 1600B.

TIOS-D is based on the Ferranti FM 1600D.

TIOS-E uses the FM 1600E computer but differs from KAFS by using privately developed software; and -E has 1 rather than 2 CRTs at each of the 3 operator stations, the same display showing both graphics and alphanumerics.

UNITED STATES

HELICOPTER SONARS

◆ AQS-13

An AQS-13 transducer suspended from a Sea King helicopter. (U.S. Navy)

The standard U.S. dipping sonar is employed primarily on carrier-based inner-zone ASW (SH-3) helicopters. AQS-13 is manufactured by Bendix and is a development of the AQS-10 of 1955.

The original AQS-13 was an MF sonar (9.25–10.75 kHz, operating at 5 kW, with 3.5- or 35-msec pulses and with range scales of 1, 3, 5, 8, 12, or 20 kyd). The typical pulse was 180 deg wide, and the sonar scanned on reception. The dip cycle, from transducer launch to recovery, was 2–3 min; and with the helicopter hovering 50 ft up, the transducer was 450 ft below the surface. Typical range was 4000 yd, and installed weight was 775 lb. AQS-13B (625 lb) had 16 preformed beams; 200 lb was saved by using hybrid microcircuits, and a single 360-deg omnidirectional ping was adopted to speed scanning. Built-in test equipment was also added. AQS-13C added a sonobuoy interface.

Sonar pulse width is 35 msec.

AQS-13E added APS (adaptive processing sonar mode) for better performance either in shallow water (reverberation limited) or in deep but noisy water (wide-band background limited) to achieve improvements of 20 and 13 dB, respectively. The usual rectangular sonar pulse, which has a wide frequency spectrum, is replaced by a cosine-squared 200-msec pulse, which has a relatively narrow spectrum and which, therefore, can more easily be separated from the surrounding noise and reverberation by FFT techniques. The longer pulse also improves target strength since it more nearly matches the acoustic length of a typical submarine. The necessary computation is done by a specialized sonar-data computer (SDC), which also processes sonobuoy data and MAD data. When the sonar operates in this mode, the usual spiral deflection system of the PPI display is not used because considerable processing intervenes between echo reception and display. The SDC places blips on the CRT to indicate computed target range and bearing; it is also responsible for refreshing the CRT display so that it does not fade.

AQS-13F was originally a lighter version (615 lb) with a longer cable (1500 ft) and higher power, saving weight by reducing all data to digital form. Two prototypes failed their U.S. tests partly because greater pressure badly distorted the beam patterns at depth. The West German navy persisted with a modified version, AQS-18. Recently the AQS-13F designation has been revived for the dipping sonar of the new SH-60F helicopter.

All versions of AQS-13 provide for voice communications;

An SH-60F carrier inner-zone ASW helicopter dips its AQS-13 sonar. (Sikorsky)

-13A added keyed (coded) communications as well, for greater range.

AQS-13 is the most widely used Western dipping sonar. Current platforms are the SH-3/Sea King (including some built under license in Italy), Agusta-Bell 204 and 212 (ASW versions), Lynx (version for Portugal), and some versions of the Sikorsky S-70/SH-60. It is also being marketed for use on board the SH-2G (which carries only sonobuoys in its U.S. version). All of these helicopters except the AB 204 are single-package, carrying both sonar and torpedoes. AB 204s operate in pairs, 1 with the sonar, 1 with the 2 homing torpedoes. Some AB 212s and 204s carry only antishipping missiles. As of 1990, current naval users of these helicopters with AQS-13 sonars are the following:

Sea King (SH-3): Brazil (8), Canada (31 of 44 CH 124As delivered), Iran (7), Italy (25), Japan (71 of 167 delivered; some are SAR aircraft), Peru (9), Spain (10), and the United States (145). AQS-13E is the current U.S. version on SH-3Hs. German Sea Kings carry AQS-18 sonars. The Spanish Sea Kings are to be fitted with new sonars.

AB204/212: Greece (16), Iran (7), Iraq (5), Italy (27 AB212s, 12 AB204Bs for training), Peru (6), Spain (11, plus 4 for ESM), Turkey (9 AB212s, 3 AB212s), Venezuela (6).

S-70/SH-60: Taiwan (10 S-70s), U.S. Navy (175 SH-60F inner-zone ASW helicopters carry AQS-13F; some may also be installed on board LAMPS-III helicopters). AQS-13 has been offered to the other major S-70 naval user, the Royal Australian Navy.

SH-2G: A sale to Portugal was canceled. As of late 1990, it seemed likely that helicopters of this type would be sold to Argentina to equip the MEKO 140 frigates, which currently operate only Alouette-IIIs.

It is not certain whether all naval AB212s and AB204s have dipping sonars; like Lynxes, some may be limited to weapons delivery, using data links and MAD (the only other important light ASW helicopters, Alouette-IIIs, HD500s, and Wasps, are so limited).

◆ AQS-14

See the Mine Warfare section under countermeasures.

◆ AQS-18

This Bendix helicopter dipping sonar was developed from the abortive AQS-13F specifically for the West German navy, for Lynx and Sea King helicopters. AQS-18 weighs 600 lb (194 lb

for the fish alone), including a 450-m cable (allowing operation down to 440 m), operating at 9.23, 10, and 10.77 kHz (3.5- and 35-msec CW pulses, 200- and 700-msec FM pulses, range scales the same as AQS-13). Source level is 217 dB. Modes include passive and MTI. Like AQS-13F, AQS-18 uses a separate transmitter and receiver. A lead-acid battery pack is carried in the sonar "fish," but there is no capacitor to store energy between pings. Instead, the helicopter recharges the battery between transmission cycles. The power level is reportedly twice that of the original AQS-13B, and the high-speed winch (22 ft/sec average) limits the dip cycle to no more than that of the earlier sonar, although the depth can be much greater.

These data are for the current AQS-18(V) version, which is available with both 1000- and 1500-ft cables.

◆ ALFS (Airborne Low-Frequency Sonar)

The flextensional transducer (projector) of the Sanders-GEC dipping sonar. (GEC)

The dipping body of the Sanders-GEC LF helicopter sonar. It is the only 1 of the ALFS alternatives not to use extending arms for more directional reception. (GEC)

ALFS is a Naval Air Systems Command project for a next-generation helicopter dipping sonar, to replace the existing AQS-13 series. The new sonar will be installed on board SH-60F carrier inner-zone helicopters (which are replacing the existing SH-3) and, on board future LAMPS helicopters. The weight target is 700 lb, and the associated signal processor is UYS-2. Proposals have been submitted by Allied Signal (Bendix), Gould/Plessey, Martin Marietta (with Diagnostic/Retrieval Systems and Breeze Eastern), Sanders, and Thomson Sintra/Hughes. The Allied Signal, Martin Marietta, and Sanders systems are described separately in the 3 entries immediately below. Thomson Sintra/Hughes offered the French FLASH (Folding Light Acoustic System for Helicopters). See the French section for details.

The Gould-Plessey proposal is a development of the Cormorant LF helicopter dipper that Plessey has developed as a private venture since 1978. See the Plessey Cormorant entry above for details of the proposed towed body. The Gould-Plessey ALFS would achieve very long sonar ranges through a combination of LF and great depth (1500 ft, with 2000 ft available as an option). A fast winch would maintain a quick dip cycle (deploy to depth and recover to fly at trail in 180 sec). This ALFS would concurrently process active sonar and helicopter-deployed sonobuoy data. Cormorant has been accepted for the demonstration phase of the Canadian HAPS project, for the new Canadian ASW helicopter (NSA, or New Shipborne Aircraft).

◆ HELRAS

HELRASt is Bendix's (now Allied Ocean Systems) LF/long-range sonar developed specifically for the Anglo-Italian EH-101 helicopter. Like Cormorant and the Martin Marietta ALFS entry, HELRAS employs a series of stave transducers on extendable vertical arms. The projector is a stacked array of 8 or 10 LF (presumably flex-tensional) transducers, 16.3 or 20.5 ft long. It extends vertically in the water; in the air, the projector is folded inside the sonar fish, the individual transducers stacking closely 1 above the other. Above the projector is a receiving array consisting of vertical staves on extending arms. When unfolded, the dimensions are 9.2-ft diameter and 4.2-ft height. The entire fish weighs either 380 or 410 lb (depending on the number of active transducers) and is 16 in in diameter and 53 or 56 in long. Total system weight, including a lightweight reeling machine, is 662 or 692 lb, depending on the number of active transducers. This weight is light enough for HELRAS to be accommodated on board an SH-60 or NH-90 (NATO Lynx successor) helicopter. Accommodation on board the SH-60 makes HELRAS a candidate for the future LAMPS or inner-zone CV helicopter.

The long array of active transducers produces a beam omnidirectional in the horizontal plane but narrowly defined in the vertical so that, for example, it can avoid multipath in relatively shallow water by grazing both bottom and surface at a very shallow angle (and at a great distance). VLF makes for long potential range; Bendix claims that HELRAS's range is about 7 times the conventional dipping sonar's range, which implies CZ performance. Given such long sonar range (and the blank zone that range implies), Bendix proposes to fuse all other available sensor data (e.g., radar and MAD) with the active and passive data picked up by HELRAS. Bendix also claims that the necessary signal processor is powerful enough to process 16 active or passive sonobuoys simultaneously.

Compared to the Plessey Cormorant, which was probably the first such LF extending-array sonar, the chief differences shown by HELRAS seem to be the much lower frequency and the very long transmitting array (to focus the beam in the vertical plane).

HELRAS flew for the first time in December 1987 on board an Italian Navy SH-3D.

The ALFS alternatives were all tested in 1989 (by March, all but HIPAS had been tried at Lake Seneca and at the AUTEC Atlantic test range). By mid-year an RFP was expected by September. However, it had not yet been issued by April 1990 (it was then expected in the near future). That probably meant no selection until late 1990 or early 1991. The decision to place the sonar on board both the SH-60B (LAMPS III) and the SH-60F

An Italian Sea King deploys the Allied Signal (Bendix) HELRAS long-range dipping sonar. (British Aerospace)

Allied-Systems's HELRAS low-frequency helicopter sonar. (FIAR)

means that it must be compatible with both the standard processors, UYS-1 and UYS-2.

◆ HIPAS

Martin Marietta's High-Performance Active Sonar is a competitor for ALFS. HIPAS uses a 5-arm array in umbrella shape, with a total of 80 transducers, with a diameter of 2 m. Total weight is 540 lb.

HIPAS has also been offered for the Canadian NSA competition and for the British EH-101 helicopter; for the latter application Martin Marietta is teamed with Dowty Maritime Systems.

◆ Sanders Advanced Dipping Sonar (Osprey)

This private-venture sonar was announced in 1988, and the prototype was tested in July. It can operate at 4 frequencies, with diverse pulse lengths, types, and shapes, and can also provide broad-band passive capabilities, acoustic intercepts, and fathometer readings. This sonar can operate at depths of 1500 ft

or more, with a dip cycle of 180 sec, trail-to-trail, and a duty cycle of 10%. Total system weight is 650 lb. Reportedly this sonar operates at about 3 kHz, using a DICASS-like cylindrical array of flex-tensional transducers. Sanders's system is the only ALFS competitor that does not employ a fold-out array.

Processing would be by the standard U.S. UYS-1 (as in LAMPS-III helicopters) or by British GEC AQS-934, which has been selected for the Anglo-Italian EH-101 helicopter.

The Sanders dipping sonar and a Thomson Sintra reeler were demonstrated on board a LAMPS III helicopter in October 1988. The transducer is about 50 in long and weighs about 160 lb.

SUBMARINE AND SURFACE-SHIP SONARS

◆ BQG-4 (PUFFS)

This passive-ranging device for submarines measures range by the curvature of the wave front of the detected sound, comparing times of arrival. The typical installation consists of 3 vertical transducers: bow, amidships, and aft; and range accuracy depends on the ratio between the range and the length of the installation. The original concept was for 3 equally spaced 6-ft (vertical) hydrophones along a 250-ft baseline, operating at 200 Hz–8 kHz, to get a range accurate to within 2% against a snorkeling submarine at 10–15 kyd.

Feasibility studies [at the Naval Ordnance Laboratory, White Oak] began in 1953 as the Passive Fire-Control Feasibility Study (PUFFS). An experimental system was installed on board the USS *Blenny* in 1956, a full prototype following in 1958. It could continuously and simultaneously display all targets within range, achieving a range accuracy of 95% and a bearing accuracy of 0.5 deg at 15,000 yd. Test installations for the nuclear *Tullibee* and *Thresher* (the prototype of all later U.S. fast nuclear attack submarines) were authorized in March 1958, and in June 1959 further prototypes were planned for ballistic missile submarines (SSBNs 608 and 609). However, the rather large PUFFS vertical hydrophone arrays were not compatible with the new streamlined submarine hull forms. The compromise solution was to fit 4 point hydrophones (slower submarines used 6 hydrophones per subarray) in a parallelogram, 2 topside and 2 bottomside. The prototype installed on board the *Thresher* (BQG-2) was defeated by self-noise; it could track noisy targets only to 4000–5000 yd, and then only with the ship extremely quiet.

The solution (BQG-2A) was to install 10 hydrophones in each of 6 subarrays (3 on each side in free-flooding spaces, and all on each side in a straight line), each beam-formed and electronically steered. The 2 after subarrays were mounted on the tips of the horizontal fins, and they could act as a PUFFS pair to obtain bearings on a target within 10 deg of the stern. This performance was actually demonstrated on board the *Thresher* when she was moored at Portsmouth, but her loss precluded an at-sea evaluation. This system was tested on board the USS *Barb* in 1964, but it was not widely installed; PUFFS was limited, in the end, to diesel-electric and to slow nuclear submarines. The idea of the 2D subarray (to defeat self-noise without imposing an impossible streamlining penalty) survived in the form of MicroPUFFS (see below) and then WAA (see BQG-5, below).

The submarine *Wahoo* shows 3 vertical PUFFS hydrophones. MicroPUFFS and WAA use 2D hull arrays instead. (U.S. Navy)

The surviving version, BQG-4A, is a modified -4 with built-in-test equipment and improved sensitivity, reliability, and maintainability.

In U.S. service, PUFFS was associated with the now-extinct Mk 45 nuclear torpedo. The torpedo had no seeker, and the firing platform had to detonate the torpedo at the appropriate range. TMA using a single sonar was not precise enough, but PUFFS could provide a good enough range. Adoption of Mk 45 was actually predicated on the success of the PUFFS tests.

A few of these devices remain in service, mainly on board submarines transferred abroad by the United States. Sperry manufactures a Micro-PUFFS for installation on board modern diesel submarines (see separate entry below). The current Martin Marietta wide-aperture array (WAA) is a lineal descendant.

◆ BQG-5/WAA (Wide-Aperture Array)

An official model of the new *Seawolf* submarine clearly shows the 3 WAA arrays on her side. (U.S. Navy)

WAA is the successor, in effect, to PUFFS and Micro-PUFFS, consisting of 3 large flat arrays on each side of a submarine. Larger array size should enable both lower-frequency operation and directivity both in depth and in azimuth, so that WAA should be able to exploit bottom- and surface-bounce paths and the CZ propagation path. The concept was first tested on board the experimental submarine *Baya* in FY71 and on board USS *Barb* in January–April 1980, presumably as part of Micro-PUFFS. By 1980 WAA was considered an essential element of any post-*Los Angeles*-type submarine. For example, in January 1977, the then secretary of defense described WAA as capable of providing bearing and range data “out to the limits of present weapons capabilities.” The current manufacturer is Martin Marietta, and WAA was tested on board the submarine *Augusta* about 1985. WAA will be fitted as a stand-alone system in *Los Angeles*-class submarines beginning with those authorized in FY89, and some will be backfitted to earlier ships. WAA will also be part of the BSY-2 system of the new *Seawolf* class.

In the past, WAA has sometimes been called RAPLOC (rapid passive localization), the “rapid” differentiating it from the much slower TMA.

As an indication of its complexity: the WAA employs 404 hydrophones per subarray (6 in all), compared to 10 per subarray in BQG-2A. Its electronics require 8 standard cabinets. The *Augusta* (SSN 710) was the trials ship.

As of early 1988, 2 BQG-5s were planned for FY89, and the total program consisted of 9 BQG-5s (plus units integrated into BSY-2 for the new *Seawolf* class).

Proposals that WAA be installed on board existing *Los Angeles*-class submarines have been scaled back because the array exceeds the very thin remaining weight margin of these ships. In June 1990 the Naval Underwater Systems Center (NUSC) announced an RFP for a demonstration low-cost fiber-optic planar array (LCPA). Two 49-element subarrays would be built in the course of a 28-month contract. As of early July, a formal RFP was expected in August 1990. The LCPA technology might ultimately be used on board an improved *Seawolf*, or it might come within the remaining weight margin of some of the *Los Angeles* class.

◆ BQH-4

Tuba II is a passive system sometimes carried by submarines collecting acoustic intelligence. About 1975 some publicity was

given to the use of *Sturgeon*-class submarines for intelligence gathering in waters near the Soviet coast, and that probably referred at least in part to the use of Tuba. Although not designed for any tactical role, Tuba was historically significant because it incorporated the first major U.S. towed array. SQR-14/15, the surface surveillance arrays, were Tubas towed by surface ships (initially *Dealey*-class frigates, in the Mediterranean, in 1969–70). The original Tuba probably used a Hughes array (for example, Hughes proposed using towed arrays for ocean surveillance as early as February 1962).

Tuba II (1971) used a combination of a retractable LF towed array on a 2600-ft cable, the submarine's own MF array (in passive mode), and its own HF subsystem in a special sonar dome. The towed array consisted of 3 subarrays (50 hydrophones each), 3 in $\times$ 258 ft, effective between 10 Hz and 20 kHz. The environmental sensors and the hydrophones modulate 52 telemetry transmitters, which are frequency-division multiplexed onto a single coaxial cable connection leading their data into the submarine. BQH-4 also used a mechanically steerable array for directional data; it consisted of 18 lead-zirconate hydrophones in a hood-shaped housing on a pedestal. All acoustic data collected were sorted and recorded on magnetic tape (by a BQH-5 recorder) for later laboratory reduction and analysis. TB-16 (of BQG-5) is a modified Tuba II array.

EDO manufactured the individual hydrophones in the Tuba array (2 in diameter $\times$ 8 in lead zirconate in a tube filled with air and elastomer).

The contract for this equipment dates from about 1969. It is unlikely that Tuba II is still used in anything like its original form, but the need for acoustic intelligence persists, and something like Tuba presumably remains in service. A Tuba III (BQH-6) program was terminated in FY78, reportedly because of cost and schedule slippage. Raytheon built 3 prototypes, and 8 production systems were planned under the FY76 budget. At that time the unit cost of a Tuba was \$937,500, slightly under half probably going for the array.

Tuba itself could not be directly adapted to any tactical role since its array design was intended more to achieve very high accuracy (in terms of sound pressure) over a broad frequency band than to achieve much directionality or directional accuracy.

Unlike the early U.S. submarine tactical towed arrays, Tuba's was retractable, probably specifically so that the submarine carrying it could operate safely in shallow water. The submarine arrays were clip-ons, the submarines having permanent inboard electronics but not permanent arrays, on the theory that fewer arrays than submarines could be purchased. Losses and damage to arrays led to the choice to shift back to retractable arrays.

◆ BQQ-5

The current U.S. standard submarine sonar suite is a digital version of the earlier BQQ-2. It is, in effect, the submarine equivalent of SQS-53, just as BQQ-2 was the submarine equivalent of SQS-26. The main improvement is DIMUS, which permits the submarine to track many targets simultaneously (pre-DIMUS spherical sonars had only 2 commutators and, therefore, could form only 2 beams simultaneously). BQQ-5 includes the BQS-13 DNA (DIMUS narrow-band accelerated active search) and BQS-14 transmitters. Compared to BQQ-2, BQQ-5 has better displays, DIMUS, improved active search, passive classification, an on-line performance monitor, and automatic fault location for quicker repair. For passive classification it uses a chin array that replaces the BQR-7 of the earlier BQQ-2. Concept formulation began in January 1969, and elements of the system were tested on board the *Pogy* (SSN 647). The prototype system was installed on board the *Philadelphia* (SSN 690). BQQ-5 was approved for service use in April 1979; an improvement program began in FY80.

BQQ-5/Mk 117 was adopted because earlier submarine FCSs were limited by inadequate sonar bearing input, by the need to plot manually for TMA, by the use of analog-digital interfaces between computer and analyzer, and by inadequate display and

retention of target information. Typical TMA range errors (10–15%) were considered unacceptable, and they could be refined only by active transmissions that would alert a target. The projected (1969) BQQ-5/MK 117, essentially an improved Mk 113 supported by a central computer complex, was expected to conduct 2 TMA simultaneously, using several TMA programs and thus eliminating the need for a manual plot. This expectation proved somewhat premature. In 1969 it was estimated that the new system would be 3 times as effective as previous ones against a standard target (a *Skipjack*).

The 2 hull arrays are the bow sphere (1241 TR-155E/BQ hydrophones) and the chin array (104 DT-276 hydrophones); later versions add a TB-16/BQ or TB-23 towed array. BQQ-5C requires 57 electronic cabinets and weighs a total of 32,000 lb. Its software comprises 311 kwords. Power requirement is 76 kW for passive operation and 566 kW for active. Active operation is at about 3.5 kHz (i.e., as in SQS-26/53), and the bow sphere operates passively at 0.5–5 kHz.

Versions:

BQQ-5 Baseline *Los Angeles*-class sonar system, using the BQS-13 sonar sphere and chin and towed passive arrays. Main components are: CP-1122 passive broad-band sonar signal processor, CP-1123 active sonar signal processor (omni, sector search, active tracker, and audio processors for each beam received from the beamformer), CP-1124 signal-classification processor, CP-1125 postclassification signal processor, J-3107 beam interface-spectrum analyzer, CV-3010 passive beam-former, CV-3011 active beam-former, CV-3035 passive beam-former, 3 control-display consoles (OJ-274), 1 performance-monitoring and fault-location console (OH-275), and 1 analog-video display (IP-1124). This version lacks a towed array; presumably, the 2 passive beam-formers operate at different frequency ranges. The chin array is for narrow-band classification (it lacks a beam-former). The active processor (CP-1123) integrates, stabilizes, and normalizes each beam received from the active beam-former. It also continuously detects 3 or 6 contiguous beams, using split beam inputs from an analog compensator to provide right/left and up/down indication and to obtain a range rate. The operator can listen to target echoes from the analog compensators, active beam-former, or active tracker processor. The passive processor (CP-1124) conditions, filters, and spectrally analyzes signals from the beam-former; its output in turn goes to a UYK-7 computer and to a classification post-processor before display. Filtered tracking data goes to the UYK-7 for automatic tracking. The CV-3035 passive beam-former uses delay-line time compression to form 25 port and 25 starboard beams as well as 2 noise beams, using signals from a BQR-7 keel array or a BQH-4 towed array. Beam steering and array selection are done at the beam-former interface unit and spectrum analyzer, which also processes the detection and tracker beams. IP-1124 uses a 10 × 10-in CRT to show any of 6 alternative presentations. IP-1125 (see below) is similar but has a 48-message projection readout switch matrix (PRASMA) instead of a 24-message PRASMA. IP-1417 is similar to IP-1125. OJ-274 is a sonar display carrying 2 CRTs, for PBB, active, DIFAR-like, or classification displays (UYK-7 outputs) selected by the operator, who also sets the system operating mode. It is controlled by a joystick. OJ-431 and -432 (BQQ-5A) are similar but somewhat larger. Later versions of BQQ-5 have later analog-video display consoles, and they lack any direct equivalent to J-3107.

BQQ-5A has improved computer capacity (in the form of an additional UYK-7) and a towed-array broad-band processor (ICC/TABP). There are 3 control consoles (OJ-431 or OJ-432) and a separate fault-monitoring console (OJ-435) and 2 analog-video displays (IP-1325 and -1417). The (V)1 version (BQS-13 sonar sphere, CP-1359 broad-band passive processor, CP-1362 active-signal processor, CP-1365 signal-classifier processor, CV-3010A passive beam-former, CV-3011A active beam-former, CV-3527 passive beam-former-processor, OJ-431 console) is for the *Los Angeles* class. (V)2 (main components as (V)1 but only 1 analog-video display, IP-1325) is for the *Sturgeon* class. (V)3 (BQS-11

sonar sphere, CP-1360 broad-band passive processor, CP-1363 active sonar signal processor, CP-1366 signal-classifier processor, CV-3521A passive beam-former, CV-3522A active beam-former, CV-3528 passive beam-former-processor, OJ-432 console, 1 IP-1326 analog-video display) is for the *Permit* class. All but some examples of the (V)3 version include a control and a remote indicator for the WLR-9 sonar intercept receiver. This sonar uses a dual-bay UYK-7 rather than the single-bay computer of BQQ-5. The interface between the beam-former and the array is changed from analog to digital, and the beam count from the beam-former is increased from 16 to 24. In addition to processing broad-band data from outside the submarine, CP-1359 and -1360 steer a pair of adjacent passive sonar beams to suppress the effect of own-ship noise. The active beam-former (CV-3011) forms a total of 600 beams, a total of 60 azimuth beams (to cover 360 deg) at each of 10 depression or elevation angles between +19 and -53 deg (for beam dimensions of 6 × 7.2 deg); it also generates the pulse waveforms for transmission. CV-3522 is similar to CV-3011 in output.

BQQ-5B has the improved control display console (ICDC, OJ-462 for (V)1 and (V)2, OJ-463 for (V)3). There is only a single analog-video display (IP-1325 in (V)1 and (V)2, -1326 in (V)3). BQQ-5B incorporates SHAB, a steerable hull-array beam-former for the chin classification array. This version is less expensive than BQQ-5A. As in -5A, the (V)1 version is for the *Los Angeles* class, the (V)2 version is for the *Sturgeon* class, and the (V)3 version is for the *Permit* class.

BQQ-5C is the major current improved version; it is an upgraded -5B, with expanded DIFAR reception (multiple interface unit/digital spectrum analyzer with 3 UYK-44 computers in 1 cabinet). BQQ-5C(V) passed operational evaluation in June 1984. The (V)1 version is for the *Los Angeles* class, and the (V)2 version is for the *Sturgeon* class. Both use the BQS-13 sonar sphere. The new passive broad-band signal processor is CP-1556 or CP-1362 (1356 only in (V)2), the new passive beam-former is CV-3770, the new passive beam-former-processor is CV-3771, and the new standard console is OJ-544 (BQQ-5C uses 4 rather than the 3 of earlier versions). The active beam-former is unchanged. (V)2 uses the same components but may have fewer than 4 control consoles. BQQ-5C introduces a separate UYS-1 spectrum analyzer (not in all (V)2s). It employs a new analog-video display unit, IP-1440 (IP-1441 in SSNs 688–99). The (V)2 version has 0 or 1 such display units.

BQQ-5D incorporates the thin-line array (TB-23) and some BSY-1 technology. Successful trials of the array were conducted in FY85. BQQ-5D completed technical evaluation in October 1988; it was operationally evaluated in November 1988 and certified in May 1989. The (V)1 version is for the *Los Angeles* class, and the (V)2 version is for the *Sturgeon* class. BQQ-5D introduces a multi-array signal beam-former and conditioner. It also incorporates a new spectrum analyzer.

BQQ-5E will incorporate TARP, a new thin-line array (TB-12X) for passive ranging. The BQQ-5E contract was awarded in December 1988. System design is focused on the localization process. BSY-1 technology in this system includes sonar for under-ice operation and mine avoidance (MIDAS, BQS-24). Technical evaluation is expected in October 1992.

The current attack-submarine version is BQQ-5E(V)3. The full-scale development contract was awarded during the first quarter of FY89, and the final hardware specification for BQQ-5E was issued during the first quarter of FY90. Future planned improvements include dual towed-array processing (presumably for a combination of TB-16D and TB-12X, as in BSY-2), lower-frequency active operation (in conjunction with the array or arrays), and a color display for the ICDC.

BQQ-5E(V)4 is a passive-only version for *Ohio*-class submarines. Work on integrating BQQ-5E and CCS Mk 2 into Trident submarines began under the FY88 program, reflecting a decision to backfit ships with complete systems rather than make incremental improvements.

BQQ-5 is associated with the WLR-9 acoustic intercept receiver, sometimes referred to as AERP (active emission receiver).

BQQ-5 procurement in recent years: 4 in FY83, 8 in FY84, 9 in FY85, 9 in FY86, 8 in FY87, 2 in FY88, 9 in FY89. This includes replacement of existing BQQ-2 systems. Existing BQQ-5s will be brought up to -5D standard.

The earlier BQQ-2 is virtually extinct. For details, see the first edition of this book.

◆ BQQ-6

The integrated sonar for Trident-missile submarines differs from BQQ-5 primarily by lacking any active element in the bow transducer. There are also a towed array and 2 flank arrays (total 100 transducers). The bow sphere includes 944 transducers. There is also an HF array consisting of 3 line hydrophones on a tracking pedestal. BQQ-6 requires 33 electronic cabinets and 430 kwords of software. About 73% of BQQ-6 components are common with BQQ-5.

Late Trident submarines will be equipped with BQR-5E(V)4, a version of BQQ-5E incorporating the thin line array but, like BQQ-6, without any active elements.

◆ BQQ-8

Rockwell's device integrates multiple passive SSBN sonars, both hull and towed arrays (BQR-2/21, BQR-7, and BQR-15), to form spherical sonar coverage. It employs multiple signal-processing techniques, automatically alerts when contacts with selectable characteristics appear, and automatically localizes and performs TMA for up to 30 separate and simultaneous contacts. All sonar data are remotely displayed in the submarine attack center, and BQQ-8 also provides a continuous equipment status display. All contact data are recorded on tape and also on hard-copy paper. There is a dual independent interface providing contact bearing data to the submarine FCS. BQQ-8 also provides geosit and target-true-motion displays (which can also show the likely results of alternative own-ship maneuvers). It incorporates a sonar performance predictor and can display own-ship and threat sonar detection-performance profiles.

Compared to its predecessors, BQQ-8 offers significantly better beam-forming using programmable beam-formers (which can take account of local acoustic conditions). It offers better search and signal-processing techniques, with integrated contact motion analysis (using several arrays together). Unlike its nondigital predecessors, it can track numerous targets simultaneously, and it introduces interactive displays. It can operate in a degraded mode and has its own performance-monitoring and fault-location element. The associated computer is UYK-20. BQQ-8 employs 3 sonar data processors and 2 spectrum analyzers, none of them standard components. There are 3 sonar-operator display consoles and 1 remote sonar-display console.

BQQ-8 was developed under a 1977 contract, and the data above date from 1980.

◆ BQQ-9

Rockwell International's towed-array signal processor can operate either as a stand-alone system or as an auxiliary to a federated submarine combat system. Rockwell claims that its advanced software and data-processing techniques allow an operator easy access to all system capabilities, with minimum training. The result, according to the company, is increased passive detection range. BQQ-9 incorporates built-in test equipment, and as of 1984 the system had passed all of its sea trials and operational evaluations. The current U.S. application is to SSBN (pre-Ohio) towed arrays.

BQQ-9 is equivalent to BQQ-8, for BQR-7E and BQR-15 sonars. It is built around a UYK-20A computer and a spectrum analyzer and has a single sonar-operator display console and no remote console. BQQ-9 uses the same memory set and the same sonar operator console as BQQ-8, but the sonars are used as separate entities (in BQQ-8, their hydrophones feed directly into the data processors and consoles of the BQQ-8 system).

◆ BQR-2B/21

BQR-2 was the passive sonar of early U.S. postwar fast attack submarines, and in its BQR-21 form it equips pre-Ohio-class strategic submarines. BQR-2B survives on board some ex-U.S. diesel submarines. The array consists of 48 staves (43-in line hydrophones) in a 68-in circle. The hydrophones of BQR-2B and -2C are lead-zirconate-titanate DT-168Bs with a nominal operating frequency of 300 Hz–15 kHz. Signals are filtered to limit them to the 0.5–15-kHz band, and twenty-four 18×30 -deg (at 5 kHz) beams are formed, the sonar using 12 left and 12 right beams for target following by BDI. BQR-2B originally had no bearing-time (waterfall) indicator, but that feature became standard in the -2E version. Bearing-time information is recorded for the 0.7–1.4-kHz band, and the BDI was accurate to within about 0.1 deg. Modes: MTB (maintain true bearing), GTT (generate target track), ATF (automatic target following), and automatic on-target slewing. There were 2 consoles (stacks) for simultaneous acquisition and processing of multiple targets and independent, continuous, recorder scanning. Sweep rates were manual or 4 rpm for each beam (recorder beam 1 or 10 rpm).

About 1960 BQR-2B was credited with a range of 15–20 nm against a snorkeling Guppy in the deep Atlantic; it was estimated that a quiet platform would be able to increase this range to 50 nm.

BQR-21 is a solid-state, passive, narrow-band, DIMUS sonar using the existing BQR-2 array. It equips U.S. strategic submarines prior to the Ohio class. BQR-21 has 96 preformed detection beams. There are 2 parallel processing subsystems, digital and analog. The linear analog beam may be trained manually or set into ATF to track as in BQR-2; the sonar has a bearing deviation indicator (BDI) as a manual-tracking aid. The cursor of the linear analog beam is presented on the digital displays. The digital subsystem converts the hydrophone signals into digital form, sums and delays them to form the 96 equally spaced preformed beams providing 360-deg coverage. Signals from each beam are averaged over 3 different periods (long, intermediate, and short), and these data are continuously available for display on 2 of the 3 CRTs. The CRTs can also display combinations of short and intermediate or long time-averaged data. The remaining CRT displays system operation modes and quantities of interest such as fire-control data. There are also 4 channels of digital ATF, so BQR-21 can track a total of 5 targets simultaneously, accurately enough for weapons delivery. The array consists of 48 DT-532/BQR-21 or DT-303/BQR-2D hydrophones arranged in a cylinder. Compared to BQR-2, BQR-21 enjoys reduced self-noise, partly through the installation of an array baffle. The sonar data processor is CP-1146(1)/BQR-21, and the display console is OJ-213/BQR-21. The system requires a total of 6–10 electronic cabinets and weighs 2100 lb.

BQR-21 equipped 13 pre-Permit-class nuclear attack submarines, now extinct. BQR-21 also works with the BQR-15 towed array and the BQR-19 receiver set and with BQQ-9. The Honeywell West Covina division received the development contract in June 1972, with sea trials of the first development model following in 1974. Procurement ended in FY82, a total of 66 having been purchased (59 tactical units, 8 trainers, and 1 configuration control unit). A planned SPAD (Signal Processing and Display) project to make fuller use of the signal-gathering ability of the array was canceled in 1974.

◆ BQR-3

This directional hydrophone occupies a small deck sonar dome on board many former U.S. submarines. BQR-3 is a trainable 5-ft line array with a 22-deg beam (but with sum/difference bearing-deviation indication for accurate direction). Typical range on a snorkeling submarine was given in 1956 as 18,000 yd.

◆ BQR-7

These conformal passive arrays (52 hydrophone groups, each of 3 hydrophones, covering a 270-deg arc) are on board pre-Ohio-

class strategic submarines. The hydrophones are lead-zirconate-titanate DT-276 or -276A (2.88 in diameter $\times$ 9.4 in). In its original form, the 50 Hz–5 kHz array was scanned mechanically at 1 or 20 rpm. Late versions (certainly BQR-7E, the final version) use DIMUS processing. The associated bearing-time (waterfall) recorder operates in the 0.5–2-kHz band. Overall system accuracy is about 1 deg, but sometimes with a 3-deg offset to take signal integration time into account. The associated bearing-deviation indicator is accurate enough for passive fire control. The array runs back about 45 ft from the submarine's bow.

In 1960 it was estimated that, on board a quiet submarine, a BQR-7 would be able to detect a snorkeling Guppy at 75 nm.

This and BQR-2/21 are the passive hull sonars of U.S. strategic submarines prior to the *Ohio* class. BQR-7 is integrated with the BQR-15 towed array by the BQQ-8 or BQQ-9 described below.

◆ BQR-15

BQR-15 was the first operational U.S. submarine towed-array sonar, on board SSBN 608- and 616-class ballistic-missile submarines. It also worked with the BQQ-3A(V) and BQQ-3B(V) passive classification system associated with the now-extinct BQQ-2 attack-submarine sonar. The short (about 120 ft) 3.5-in array carries 42 hydrophones, and the inboard electronics require 9 cabinets. The large array diameter is due in part to the use of a relatively simple technology, twisted pairs to carry the hydrophone outputs. Total weight (probably only of the array proper) is 950 lb. In addition to submarine signatures, BQR-15 can receive underwater telephone signals (from UQC-1 and WQC-2). BQR-15 was introduced largely to give strategic submarines the ability to detect targets on aft bearings, hidden in the baffles of the bow sonars. BQR-15 incorporates the BQR-23 signal processor. It is associated with the new BQQ-9 processor.

The JMSDF tested this array on board the submarine *Okishio* in 1988–89, to integrate it with ZQQ-5 or -5B.

◆ BQR-19 (Top Hat)

Raytheon's mast-mounted short-range navigational sonar for SSBNs is designed for evasion while surfacing. Its array is a 24-stave cylinder (DT-374/BQR-19 hydrophones), and inboard electronics consists of 3 cabinets, weighing a total of 1000 lb.

◆ BQR-20A/22/22A

Spectral Dynamics's signal processor for improved narrow-band detection and classification is based on the SQQ-23 passive receiver, with added passive-classification equipment. It is found on board all U.S. pre-*Ohio* strategic submarines as well as *Los Angeles* and earlier attack submarines; it is also in British service. Work began in the late 1960s; the BQR-20 contract dates from 1971, and BQR-22 from 1974. The parent firm, Scientific Atlanta, has proposed that BQR-20 be replaced by the more capable BQR-23. BQR-22 is similar. It can be connected to a dual-channel hard-copy (LOFARgram) recorder. BQR-22A can be used as a dual-channel system and adds a remote range-rate indicator. BQR-20 and the improved BQR-22 require 1–5 electronic cabinets, weighing a total of 500 lb.

BQR-20A is the SQQ-23A passive signal processor. It entered service as such in 1975.

◆ BQR-23

BQR-23 is a towed-array signal processor manufactured by Scientific Atlanta (originally by Spectral Dynamics), used with the BQR-15 and -25 arrays and as part of BQQ-5. It provides at least 64 channels of data simultaneously in real time, with a visual display. Sonar signals are classified by LOFAR analysis.

The original BQR-23 contract was awarded in 1974. Versions: BQR-23, -23A, -23A(V)1 through (V)6.

◆ BQR-24

BQR-24 is a signal processor and beam-former added to BQS-11, -12, and -13 sonars on board SSN 594/637-class submarines as

an alternative to installation of the full BQQ-5. In effect it is the first stage of conversion from BQQ-2 to BQQ-5. It is described here as an indication of the sort of capability improvement BQQ-5 entails. The earlier BQQ-2 formed beams in analog fashion. The wiring from the individual sonar transducer elements was led to equivalent elements in a pair of small spheres. Commutators moved over the surfaces of the spheres to form beams, picking up signals from the sphere elements with the appropriate relative phases. In this sonar (as in BQQ-5) the mechanical commutators and their small analog spheres are eliminated. They are replaced by a digital beam-former, for full DIMUS operation. BQR-24 provides the earlier spherical bow sonars with a preformed-beam, passive, broad-band, detection capability (DIMUS); a high-resolution, wide-frequency-range, narrow-band, spectral analysis and display capability (digital LOFAR); a frequency-line tracker capability; improved TMA capability; computation and display of acoustic propagation paths, ray-path trace and associated environmental data, and self-contained test and training capability. BQR-24 consists of a signal-data processor, a passive DIMUS beam-former, a recorder, and 2 monitors; total weight is 2100 lb. BQR-24 was approved for service use in 1974, and 11 were bought under the FY76 program.

◆ BQR-25 (STASS)

This was the original stand-alone Submarine Towed-Array Sonar system, predating the TB series integrated with BQQ-5 and -6. The clip-on "wet end" was made by Gould. BQR-25 consists of a beam-former and a 298-ft (2–2.4-in diameter) DT582/BQR acoustic array towed on an 800-ft (1-in cable). The 550-lb array consists of 4 LF hydrophone modules, 1 stabilization module, and 2 VIMs (150 and 300 lb). The signal processor is BQR-20A, BQR-22, or BQR-23. BQR-25 is used on board some SSN 594/637-class submarines and was previously on board SSBN 598-class strategic submarines; in 1981 it was on board 18 SSNs and 3 SSBNs. Inboard electronics consists of 3 cabinets, weighing a total of 200 lb.

◆ BQS-4

The successor to SQS-4 for submarines, BQS-4 consists of 7 vertically stacked cylindrical transducers inside a passive sonar (BQR-2C) that acts as receiver. Vertical stacking permits beam movement in the vertical plane. BQS-4 operates at 7 kHz, and typical range is 6–8 kyd. BQS-4 is found in older U.S. diesel and nuclear submarines.

◆ BQS-13

The bow-sphere sonar of the BQQ-5 system, this DIMUS narrow-band accelerated-search (DNA) sonar superseded the mechanically scanned unit (BQS-6 and successors) of the earlier BQQ-2. The effect of DIMUS was to greatly increase the number of targets that the sonar could track; BQS-6 was limited because it had 2 commutators. As an approximate measure of BQS-13 performance, BQS-6 transmitted at about 3.5 kHz (i.e., like SQS-26/53) and listened at 1–2.8 kHz. Rated output was 75 kW, and sphere diameter was 15 ft.

◆ BQS-14/15

Under-ice and mine-avoidance sonars, these HF sets are part of BQQ-2, -5, and -6.

Hazeltine's BQS-14 was on board 22 *Sturgeon*-class submarines in 1981. It employs a cylindrical transducer with 30 dual staves, as well as a projector (TR-215/BQS), an HF transducer (TR-217), and 7 LF transducers (TR-216). Internal electronics occupy 6 cabinets, and the system as a whole weighs 2200 lb. BQS-15, the under-ice sonar of the *Los Angeles* class, consists of 3 line projectors, tracking pedestals, 2 HF transducers (TR-282), 4 LF transducers (TR-281), and 4 cabinets of inboard electronics, for a total of 3300 lb.

◆ BQS-()

This is a new submarine sonar with significantly better mine-hunting and under-ice-navigation capability. No details have been published.

◆ BQS-24 (MIDAS)

This HF minehunting and under-ice-navigation sonar for *Los Angeles* and *Ohio* classes is part of BQQ-5E. Specifications were finalized in FY89, and development began in FY90. Full-scale engineering development is scheduled for FY91, with a full-scale development award due in October 1991. The MIDAS concept had already been tested on board the *Richard B. Russell* about 1986; MIDAS probably occupied the large dome mounted aft at that time. Released paintings of the new *Seawolf* show a sonar window in the appropriate position at the upper forward part of the sail. MIDAS, Mine Detection and Avoidance Sonar, is sometimes linked with SADS, Submarine Active Detection Sonar, as SADS/MIDAS.

◆ BSY-1 (SUBACS)

The submarine integrated combat system replaces BQQ-5 in the last *Los Angeles*-class submarines. It was originally designated BYS-1 and apparently redesignated as the result of a typographical error; BSY-1 is now pronounced "busy-one." It appears to have been conceived as a submarine equivalent of the SYS series of systems on board AAW ships and also of the SQQ-89 on board newer ASW ships: a system that would automatically detect targets on a variety of arrays and meld these data (obtained in various frequency ranges) into a single usable tactical picture. One advantage of such detection would be the ability to range passively on a target detected simultaneously (in different frequency ranges) by several arrays, e.g., by a towed and a flank array. As in SQQ-89, the minimum required for integration is that adjoining consoles be able to show the output of any array, for comparison and correlation. That in turn requires that sonar data be carried by a data bus available to each console. As in

SQQ-89, once passive target data have been fed into the central computer system, multiple targets can be tracked automatically. In BSY-1, unlike its predecessor (BQQ-5/Mk 117), there is sufficient computer power to allow the operators considerable interaction with the evolving computed TMA solutions. Given that degree of interaction, operators are much more willing to forego the paper tracking previously demanded (and, as it often turned out, needed) as a check on the computer.

BSY-1 incorporates a new Combat Control System (CCS Mk 1), which replaces the Mk 117 of earlier submarines. The arrays match those of BQQ-5, but the sphere uses new transducers (TR-217/218 for the sphere). BSY-1 also incorporates WAA (BQG-5) and the thin-line towed array.

IBM was responsible for overall system design, with Hughes developing combat-system displays, Raytheon the CCS and the WAA, and Rockwell the own-ship data-set group. The 2 basic elements of the system were a multipurpose console incorporating a new densely packaged electronic card, and the high-capacity fiber-optic data bus tying the consoles together. A submarine would have 11 such consoles arranged side by side, but only 4 would be required for operation. It would be unnecessary to perform maintenance during a patrol; any console that failed could be taken out of line and replaced by 1 of the others. The adoption of the multipurpose consoles replaced the separate FCS of the past with a CCS embedded in system software.

In practice the dense packaging proved much more difficult than had been expected, and the data bus also encountered difficulties. BSY-1 had to be recast. It now employs a variety of different consoles: 4 control-display units, 2 different multipurpose units, 4 weapons-control consoles (3 Mk 81 Mod 3, 1 Mk 81 Mod 2), 1 command launch-control console, and 4 weapons launch-control consoles (1 vertical). There are 3 tactical data processors and 1 UYK-7 computer. BSY-1 incorporates 2 graphic plotters (Mk 23 Mod 0), 2 computer plotters, and 1 Mk 19 Mod 20 (see the Mk 101 FCS for a description of the original Mk 19). There are 2 signal conditioners, 1 for the bow sphere and 1 for multi-arrays (WAA and towed array, presumably). There is also a console for acoustic support (presumably, for the intercept receiver or receivers).

As of 1985, the program had been split into 3 versions:

SUBACS Basic, for FY83 submarines (scheduled for delivery

BSY-1 configuration, showing both the bow sphere and the chin array (the latter is not highlighted). There is also a towed array. (IBM)

1987): distributed acoustic processing, UYK-44 computers, thin-line towed array, and SADS/MIDAS active sonar for submarine and mine detection.

SUBACS A (FY86 submarines for delivery 1989) added an enhanced modular signal processor (EMSP), distributed combat control, a piloting and combat system (PACS), a combat-system display console (CSDC), and common displays. SUBACS A employs a new bus interface unit and is an application of VHSIC technology. The term PACS suggests some measure of automatic maneuvering, presumably for torpedo evasion or perhaps for faster and more precise TMA.

SUBACS B (FY89 submarine, the new *Seawolf* class) added the WAA and improved ESM and external countermeasures (presumably antitorpedo decoys).

In fact, as noted, this program could not be met and had to be split between BSY-1 (which IBM retained) and BSY-2 (which went to GE).

The first BSY-1 was delivered in July 1987, for installation on board the attack submarine *San Juan* (SSN 751). BSY-1 represents an improvement in passive sonar capability and in some weapons control. A further post-completion upgrade, for the *San Juan* and the next 4 *Los Angeles*-class submarines, will be installation of new UYK-43 computers, new software, active sonar improvements, under-ice capability, and new weapons capability (presumably Sea Lance). This 2-phase approach was chosen when the SUBACS program was restructured in May 1985. From SSN 756 on, submarines will be completed with the full BSY-1 suite.

BSY-1 uses distributed processing to support a combat-control subsystem and an acoustic subsystem. This integrates BQQ-5, SADS/MIDAS (see below), the thin-line array (TB-23), and CCS Mk 1 (Mk 117 plus OTH-T). The system will initially use the improved control-display consoles (ICDC) and Mk 81 WCC (weapons-control console) of the BQQ-5/CCS Mk 1 system, the UYK-7(V) computer of BQQ-5/CCS Mk 1, tri-advanced signal processors (TRIASPs), and the active emission-receiver processor (sonar-intercept receiver) of BQQ-5. New features are the weapons-launch system (WLS), the common beam-former cabinet (CBC), and a modified plotter Mk 19.

IBM describes BSY-1 as the first military application of distributed architecture on a large scale. BSY-1 employs 1 UYK-7 and 1 UYK-43, supported by 2 UYK-44 minicomputers; presumably the retention of the older UYK-7 reflects commonality (in some software) with earlier *Los Angeles*-class systems. There are also 5 linear beam-formers, 2 digital (DIMUS) beam-formers, and 6 advanced signal processors (in the form of 2 TRIASPs). Overall, the system has 30 MCOPS in raw general-purpose computing power, supported by 60 Mbytes of on-line RAM storage and 400 Mbytes of disk storage. The computer power required for signal processing dwarfs general-purpose power: 120 MCOPS of signal processing, 800 MCOPS of linear beam-forming (for towed arrays, presumably), and 2 GCOPS (giga-COPS) of DIMUS beam-forming. All of this power requires about 4,519,000 lines of instruction code. Total weight is 32 tons, and total power requirement (aside from the transmitter) is 142 kW. The system occupies 117 units with 11.5 miles of wiring. Presumably, the enormous amount of wiring reflects the failure of the optical-fiber data bus originally planned.

Improvements over BQQ-5 include much better fault detection and a greatly reduced number of logic cards.

BSY-1 is to be upgraded with a new CCS Mk 2, a program awarded to Raytheon/General Dynamics in September 1988. See below.

The BSY-1 Operational Requirement (OR) was issued on 17 April 1980. As of November 1988, a total of 21 BSY-1 were on order or had been delivered (20 for submarines, 1 as a trainer). FY88 deliveries were for SSN 752 and 754. FY89 deliveries: 753, 755-57. FY90 deliveries: 758, 759-62. FY91: the program is completed with SSNs 763-69. The first full-function model was delivered in February 1989 for the *Miami* (755). SSN 751 will be the first of the first 4 BSY-1 to be retrofitted to full-function standard. Techeval and opeval were scheduled for 1990.

This was the first U.S. submarine sonar system formally to integrate sonar and fire-control functions; in this sense it is analogous to SQQ-89/Mk 116.

Unit cost is \$43 million.

◆ BSY-2

BSY-2 is the combat system of the new *Seawolf*-class submarine. The program was split from BSY-1 when the latter encountered severe problems in 1985-86. BSY-2 retains the original goal of largely distributed processing, with multifunction consoles (MCCs) and combat-system display consoles (CSDCs), a horizontal plotter (HP), and a tactical-situation display (TACSIT). A published drawing (1989) shows 6 ship data displays and 11 consoles, 3 of them for the CCS. Software is to be written in ADA.

The major system sensors are a large spherical bow array (LSA, spread over the surface of the bow), an LF bow array inside the bow (LFBA), an active hemispherical array (AHA) below the LFBA (using a transmit group, TG), an HF array (HFA) in the sail (for SADS/MIDAS), the WAA (BQG-5), a long thin-line (TB-12X) towed array, and a shorter TB-16D array. The long thin array is associated with TARP, the towed-array range processor. The same system processes all 7 arrays to form a coherent tactical picture. As in earlier integrated sonars, passive targets are detected primarily by automatic line integration (when the strength of a line exceeds a threshold, the target is detected and inserted into the system). BSY-2 differs from its predecessors in the number of lines and frequency ranges it can surveil simultaneously. All sonar output flows into array processors for signal conditioning and beam-forming. Outputs go into signal processors (UYS-2s) and also into the workstations/functional processors. The latter also receive processed signal data. The workstations are connected with the weapons launch system by a flexnet data bus, and they also feed into the combat system's display consoles. There is no central computer. The system as a whole comprises 61 enclosures, and it requires a total of 570 kW and a maximum of 157 gal/min of cooling water.

General Electric is the prime contractor; the company received the BSY-2 full-scale development (FSD) contract in March 1988. Librascope is responsible for multifunction displays, and Martin Marietta makes the WAA.

The first unit is scheduled for delivery in May 1995. As of December 1989, there was some fear that the initial unit would be 12-16 months late, largely because GE might not be able to train enough ADA programmers quickly enough. The navy's approach has been to develop the software in modules (threads), so that the initial *Seawolf* will have at least the minimum required capability. Since the feared limitation is in software rather than hardware, later upgrading to full capability should be simple and inexpensive.

BSY-2 uses about two hundred 68030 microprocessors. It is broken down into 4 subgroups: acoustics, command/control, weapons, and display. The system is made highly redundant through the use of common hardware running different software. In the weapons section, each of the 4 processors has a designated backup. In each of the other groups there are 2 or 3 spares. Thus, each cluster can shift to other processors within itself as not all are used simultaneously. If necessary, any function can be shifted to processors within another cluster (other functions are slowed or stopped). The loss of functions is prioritized.

◆ QBE-3

This 18-25-kHz searchlight sonar, with a typical range of 1 kyd (max indicated range 5 kyd), was standard aboard U.S. 83-ft coast guard cutters transferred abroad. It reportedly survives at least in the Turkish navy. QBE is a converted passive sonar in a fish-type retractable dome, using a 15-in-diameter transducer. In the U.S. World War II system of designations, QB denoted a sonar with a rochelle-salt transducer.

◆ QCU-2

This World War II searchlight sonar is still in use in a few U.S.-built ships of that period and in some small patrol craft transferred postwar. Frequency is 17–27 kHz (centered on 25 kHz). Range scales are 1, 2, 4, and 6 kyd (associated pulse lengths 25, 75, 75, and 200 yd, respectively). In the U.S. World War II system of designations, QC denoted a sonar with a magnetostrictive transducer.

Current installations: Greece (*Cannon*-class frigates), Italy (*Albatros*-class corvettes), Portugal (*Joao Coutinho* class), Spain (P311-class patrol boats), Thailand (PC 461 class). This sonar was also supplied to foreign navies on board ex-U.S. 95-ft coast guard cutters and their PGM derivatives. QCU-1 was standard on board the PGM 39 and PGM 53 classes. This sonar may also survive on board other ex-U.S. warships. SQS-17 was, in effect, the successor sonar. On board PGMs, however, it was limited to a few special ASW units for the Iranian and Turkish navies.

◆ SQQ-14

See the Mine Warfare section under countermeasures.

◆ SQQ-23

See SQS-23 below.

◆ SQQ-25

This high-definition 3-D sonar is found on board the submarine rescue ships *Ortolan* and *Pigeon*. SQQ-25 uses a 7-kHz chirp. Active range is 2500 yd; passive, 1000 yd.

◆ SQQ-28

The LAMPS-III shipboard processor is the successor to SQS-54. SQQ-28 was later extended to LAMPS-I support, for *Perry*-class frigates assigned to Naval Reserve units. SQQ-28 can process all buoys up to and including VLAD (SSQ-77).

◆ SQQ-30

See the Mine Warfare section under countermeasures.

◆ SQQ-32

See the Mine Warfare section under countermeasures.

◆ SQQ-34

This is a CV-ASW module, part of a carrier's CDS. It is a semi-automated system, the primary source of external data to the battle group ASW commander. It also provides all information for the carrier's own ASW aircraft (S-3, SH-3, and SH-60F). This system was originally the CV-Tactical Support Center and was renamed in 1979.

◆ SQQ-35

See the Mine Warfare section under countermeasures.

◆ SQQ-89

General Electric's integrated surface-ship sonar and fire-control suite is analogous to the submariners' BQQ and BSY series. Each version includes an on-board trainer, SQQ-89T(V). The first ship fitted with SQQ-89 was the *Spruance*-class destroyer *Moosebrugger*, which also had the prototype SQR-19 towed array (1985); she was followed in 1987 by *Fife*, *Fletcher*, and *Spruance*, 5 more ships following in 1988. The first FFG 7-class frigate to receive the new system was *Curtis* (1985), followed in 1986 by *Elrod* and *Simpson* and then by 5 ships in each of 1987 and 1988. From the *San Jacinto* (CG 56) on, newly completed Aegis cruisers will have SQQ-89 as initial equipment.

SQQ-89 was conceived under the ASW Combat System Integration (ASW-CSI) project, to handle the much larger number of passive contacts provided by the modernized SQS-26 (SQS-53) sonar and the towed array. Nothing short of a computer could keep track of several passive targets, conducting several TMA analyses simultaneously, so existing manual ASW

CDSs had to be replaced. The track-keeping computer is part of the Mk 116 Mod 5 or later FCS embedded in SQQ-89 (the *Perry*-class version lacks the Mk 116, but instead uses a weapons alternate processor [WAP] as its track-keeping computer). SQQ-89 also includes SIMAS (UYQ-25), which helps estimate the effective range of the passive sensors. The sensor side of SQQ-89 was originally developed as SIADS (sensor integration and display sharing); a shore test site was established at NUSC New London in 1980.

Presumably, SQQ-89 supersedes the experimental Mk 119 digital surface-ship underwater FCS, which employed submarine consoles (such as Mk 81), and which was installed at NUSC San Diego about 1980.

SQQ-89 is the latest and by far the most successful of several attempts to produce an ASW equivalent to the highly automated AAW-oriented CDSs; it might be considered an ASW equivalent to Aegis. It requires about twice as many lines of source code as does the Aegis system, mainly for the multiple-target TMA.

All versions of SQQ-89 employ SQR-19 towed arrays and LAMPS III helicopters (SQQ-28) as their passive sensors; most versions also incorporate SQS-53B/C sonars. The display consoles are OJ-452/UYQ-21s. The combination acts as a sort of underwater equivalent to NTDS. Operators at the OJ-452 (UYQ-21) displays detect the targets (i.e., decide when passive sensors are showing real targets) and enter them into system memory. The Mk 116 (Mod 5 or later) computer (WAP in a *Perry*-class frigate) compiles what amounts to a full tactical picture and conducts the multiple simultaneous TMA. Mk 116 in turn inserts target data into the ship's NTDS system.

The sonar supervisor has some of the role of the track supervisor in NTDS but generally does not have a dedicated console (only versions now in development provide the supervisor with a dedicated console, and there is some disagreement as to whether that is a wise development).

Mk 116 also receives data (particularly ESM and radar data) from the ship's NTDS. These data can be used to eliminate nonsubmarine contacts, or to identify potential surface targets (which can be detected by their sound emissions, beyond the visual or radar horizon). Mk 116 automatically inserts its contact data into NTDS, which in turn can pass targets for Harpoon targeting.

Sonar data are fed through (and controlled by) UYK-20 computers and 1 (*Perry* class), 2 (1 master, 1 slave), or 3 OL-190/UYQ-21 acoustic-data converters, each of which can support 2 OJ-452/UYQ-21 acoustic-display consoles. Each sensor subsystem uses 1 or more UYS-1 spectrum analyzers. SQQ-89 includes the UYS-1 processor of LAMPS data (the other sonars include their own processors). Any UYQ-21 console can display data from any of the sonars. For example, an operator can switch between an SQR-19 display showing a CZ contact and an SQQ-28 display showing a LAMPS helicopter prosecuting that contact. Each UYQ-21 shows only 1 sensor at a time; it is provided with 2 screens so that different frequency ranges (or bearing-time and frequency-time) can be displayed at the same time. Any 2 sensor outputs, then, can be displayed side by side (on 2 UYQ-21 consoles) for visual correlation by a sonar supervisor. For example, a passive (SQR-19) and an active (SQS-53) picture of the same contact can be shown side by side. In the version using Mk 116 Mod 7, an acoustic sensor console can also be used to replace the Mk 116 display.

Side-by-side comparison was impossible in earlier systems, which relied on paper LOFARgrams and lacked any electronic memory. SQQ-89 achieves its high performance because several operators can see the same displays together; a total of 7–9 people work the ASW problem together. Moreover, the system uses LAMPS III as a sensor, fully equivalent to the 1 or 2 hull sensors because the data link has such a wide bandwidth and, thus, can transmit sonobuoy data so fully.

In a typical version, a (V)3, 3 of the UYQ-21 consoles are lined up together, separated from the fourth by an equipment rack

SSQQ-89(V)2, the version for frigates, without a large hull sonar. (GE)

AN/SQQ-89(V)4 SURFACE ASW COMBAT SYSTEM

USD-19

SQQ-89(V)4, the fully integrated version of the system, in which the Mk 116 element is nearly vestigial. (GE)

containing a control indicator, a time code/control box, a data terminal set (UYQ-69), and a pair of audio amplifiers. The 2 acoustic-display converters are at the ends of the row of display consoles. The 3 consoles working together might be divided into 2 for SQS-53 and 1 for SQR-19, with the fourth also used for SQR-19. Presumably, 1 of the SQS-53 consoles would be switched to SQQ-28 when a helicopter was launched to prosecute a contact.

SQQ-89 was originally a combination of multipurpose sensor displays weakly integrated with a track-keeping computer in a modified Mk 116 FCS. Only in the later versions, (V)4 and above, is the distinction between sensors and fire control eliminated (as in Aegis).

Each sensor has its own embedded UYS-1 and UYQ-21 separate from SQQ-89. These UYQ-21s are for the *sensor* operators; they are equivalent to the radar repeaters. The SQQ-89 UYQ-21s are for target detectors inserting targets into the combat system, a very different role.

The latest improvement to the SQQ-89 series is the insertion of an acoustic video processor (AVP) into the lower drawer of the UYQ-21 to provide better graphics. This is display, not signal processing, technology.

The SQQ-89 unit cost was \$27–28 million (FY90). R&D began in FY76, with interface definition in FY78. Concept formulation was completed in FY79, and full-scale development in FY81. Initial operational tests were conducted on board the *Moosebrugger* in FY84, and the first production model was installed in FY86; full-scale procurement began in FY87. Design of the version using the UYK-43B computer was completed during FY86.

Versions:

Prior to (V)6, destroyers and frigates all have SQQ-28(V)2; cruisers and Aegis destroyers have SQR-28(V)3. SQQ-89(V)5 and later all have SQQ-28(V)9, a version that shares a UYK-44 computer with the SQR-19 array; the computer is called a signal-data processing unit (SDPU). All versions from A(V)3 onward use UYQ-25A(V)2; only (V)2 and (V)3 use UYK-20 for SIMAS (the others use the non-Mil-Std 9020C version). Versions of SQQ-89 differ in the versions of Mk 116 around which they are built. As of November 1990, plans called for installations on board 19 CG 47, 39 DDG 59, 30 DD 963, and 51 FFG 7 class units; there are apparently no plans for installations on board DDG 993-class ships. Numbers already certified (number in process in parentheses): CG 47, 11 (2); DD 963, 13 (5); and FFG 7, 26 (2). There are also 8 stand-alone SQQ-28s that will become part of SQQ-89s when other subsystems are installed. UYQ-25A(V)2 installations at present: 13 for the CG 47 class, 12 for the DD 963 class, and 21 for the FFG 7 class.

(V)1 for DD 965, 980, and 992 uses Mk 116 Mod 5 with SQR-19(V)3, SQS-53B(V)1, and UYQ-25A(V)2. There are 4 OJ-452(V)8/UYQ-21(V) consoles in the sonar-control space, with an OJ-452(V)11/UYQ-21(V) in CIC near the weapons-control panel (Mk 329). Two of the OJ-452s in sonar control flank a computer unit including a USQ-69. In this version, sensor data are fed into a group of 4 OJ-452/UYQ-21s fed by 2 OL-190/UYQ-21 acoustic-data converters: 3 adjacent display consoles plus a running spare and a data terminal (USQ-69). The system employs 2 UYS-1 spectrum analyzers, 1 of them connected directly to SIMAS. This version incorporates 4 UYK-20 computers, 3 for the spectrum analyzers and 1 for the signal conditioner and receiver (feeding into a UYH-2 disk memory set). The 3 UYK-20s feed into the SQQ-89 acoustic-display converter. The associated Mk 116 Mod 5 uses an additional OJ-452/UYQ-21 display and a 3-bay UYK-7 computer. First installation was in the *Moosebrunner* (DD 980).

(V)2 is the version without any integrated SQS-53 or Mk 116. There are 2 subvariants: (V)2 CG for CG 54 and CG 55 only, with SQR-19(V)1 and UYQ-25; and (V)2 FFG for FFGs 7-9, 11-13, 15, 28, 29, 32, 33, 36, 38-43, 45-49, 53, and 55-61, with SQR-19(V)2 or -19A(V)2 and UYQ-25A(V)2. In the CG version, 2 OJ-452(V)9/UYQ-21(V)s, for ASO and ASO-ALT (acoustic-sensor operator and acoustic-sensor operator/alternative), flank a computer console carrying the USQ-69. The relevant consoles in CIC are 2 OJ-194(V)4/UYA-4(V)s, for the underwater-battery supervisor (UBS) and for the ASW air supervisor (ASAS), and the standard horizontal console (OJ-197/UYA-4) for the surface-warfare coordinator (SSWC). In the FFG version, sonar control includes a similar pair of OJ-452(V)8/UYQ-21s flanking a console carrying USQ-69, plus an SQS-56 console, tape recorders, and a UYQ-25A and a UYK-20X(V). CIC includes the training console and another UYQ-25A. This version uses a weapons alternate processor (WAP, in effect replacing Mk 116). First installation was in the *Curts*.

(V)3 with Mk 116 Mod 6 has 2 variants: (V)3 CG for CGs 56-64, with SQR-19(V)1 or -19A(V)1, SQS-53B(V)2, and UYQ-25 or -25A(V)2; and (V)3 DD for DDs 963-964, 966-968, 970, 971, 973, 975, 981, and 991, with SQR-19(V)3/A(V)3, SQS-53B(V)1, and UYQ-25 or -25A(V)2. A(V)3 for CG 65 only uses Mk 116 Mod 7 with SQR-19B(V)3, SQS-53B(V)2, and UYK-25A(V)2. The CG version has 5 OJ-452(V)s in a row, 2 of them flanking the USQ-69 console. CIC contains an OJ-452(V)10, 2 OJ-194(V)4s, and the usual horizontal OJ-197 console. The destroyer version has 4 OJ-452(V)8s in sonar control and an OJ-452(V)11 (with the Mk 329 panel) in CIC. A(V)3 is the first version with a UYK-43 computer (instead of UYK-7). First installation was in the *San Jacinto* (CG 56). This version is very similar to (V)1.

(V)4 for DDG 51 (the *Arleigh Burke*) only uses Mk 116 Mod 7 with SQR-19B(V)3 and SQS-53C(V)1. Sonar control contains 5 OJ-452(V)9s, 2 USQ-69s, and the UYQ-25A(V)2; CIC contains an OJ-452(V)9 (for the ATS/FCO) and 2 OJ-451(V)s (for the ASWC and the ASAC). This version has 3 acoustic-data converters, serving 6 OJ-452s: 4 for the acoustic operators, 1 for the sonar supervisor (SS), and 1 for the ASW-control system operator (ASWCSO). In addition, the system is connected to 2 OJ-451/UYQ-21s in CIC, for the ASW evaluator (ASWE) and the fire-control operator (FCO); they are connected via a fourth acoustic-data converter. The computer is UYK-43(V)7: 1 for the weapons-control system (WCS), 1 for command and display (C&D), and 1 for the Mk 116 Mod 7. Mk 116 Mod 7 uses nearly 215,000 lines of computer program code. The UYQ-21 display formats include NTDS-style PPI as well as bearing/frequency analysis and TMA.

(V)5 with Mk 116 Mod 8 is for DDs 966-968, 970, 971, 973, 975, and 980-982; it uses SQR-19(V)3 or -19A(V)3 and SQS-53B(V)1. Ships are to be upgraded to this standard after FY90. The equipment in CIC and in sonar control corresponds to that in the (V)3 destroyer version. The computer is UYK-43(V)8.

(V)6 uses Mk 116 Mod 7 or (for DD) Mod 7/VLS. There are 3 variants, (V)6 CG for CGs 68-73 and (V)6 DDG for DDGs 52-58, both with SQR-19B(V)1 and SQS-53C(V)1; and (V)6 DD for DDs 978 and 985-988, with SQR-19B(V)3 and SQS-53C(V)2. The equipment configuration matches that of (V)3 (for destroyers and cruisers) and (V)4 (for Aegis destroyers). The computer is UYK-43(V)7.

(V)7 with Mk 116 Mod 7 is for CGs 66-67, with SQR-19B(V)1 and SQS-53B(V)2. The equipment configuration matches that of the (V)3 cruiser version. The computer is UYK-43(V)7.

(V)8 with Mk 116 Mod 8 for VLS ships and Mod 9 for non-VLS ships is for DDs 969, 972, 974, 976, 977, 979, 982, 983, and 997, with SQR-19B(V)3 and SQS-53B(V)1. The equipment configuration matches that of the (V)3 destroyer version. The main computer is UYK-43(V)8 and (V)9. A projected A(V)8 version has OJ-653/AVP instead of OJ-452 displays and also has a UYK-43(V)9 computer.

(V)9 for FFGs 14, 20, 30, 31, 34, 37, 50-52, and 54 lacks any version of Mk 116. It works with SQR-19B(V)2. The equipment configuration matches that of the (V)2 frigate version.

(V)10 is the future projected version for the DD 963-class and later Aegis destroyers, with OJ-653/AVP instead of OJ-452 displays. The main processor is UYK-43(V)7.

(V)11 is the future projected FFG version, with OJ-653/AVP instead of OJ-452 displays.

◆ SQQ-89I (SQY-1)

SQQ-89I, i.e., SQQ-89 Improved, is the next-generation surface-ship sonar system, incorporating the new technology of an LF active source and a multiline towed-array receiver. The TOR was issued in February 1985, and the OR that December. The system uses the UYS-2 processor and the OJ-535/AVP display.

FY89 efforts included classification algorithms, systolic adaptive processing/beam-forming techniques and evaluation of competing *Perry*-class SQQ-89I FFG technical proposals. The FY90 program included fabrication of advanced development models of low-cost towed arrays and the development of an advanced model of a sonar optical signal processor.

There are 2 parallel versions, an austere type for convoy escorts (i.e., for the *Perry* class), and an advanced version for Battle Group Escorts (BGE), i.e., CG 47/DDG 51/DDG 993/DD 963. The program is phased in blocks. Block 1 is essentially a software upgrade; Blocks 2 and 3 are the hardware upgrades.

For the *Perry* class, Block 1 provides all the improvements needed to satisfy the OR, except for the active upgrade. Block 1 for the BGE consists of upgrades based on mature computer algorithms already, in some cases, in use in air or submarine systems. *Perry*-class Block 1 installations should begin in FY90.

Block 2 is the *Perry*-class active upgrade. The experimental frigate *Glover* has been modified with an active LF emitter in her bow dome (installed FY88 and tested FY89). Competitive design-definition contracts were awarded in FY88, and FSED should begin in FY90. The first *Perry*-class Block 1 system should be delivered in the second quarter of FY93 (i.e., early 1993), and operational and technical evaluation should be completed in the first quarter of FY94 (late 1993). Production Block 2 deliveries should begin in the third quarter of FY97.

Block 3 is the active upgrade to the BGE. As in the case of the frigate, FSED should begin in FY90. As of early 1989, first Block 1 (BGE) production deliveries were scheduled for the first quarter of FY96, with Block 3 (BGE) following in the third quarter of FY98.

Efforts beyond Block 3 will be devoted to the development and evaluation of multistatic sonar (see also BGMSS).

As of 1990, there was speculation that SQQ-89I would be limited, at least at first, to only a few ships. There was some suggestion that it might be installed only on board FFG 7s and future air-capable battle-group escorts, on the theory that early DDG 51s, which cannot operate helicopters, cannot fully ex-

plot it. The 2 competitors were GE and Westinghouse, but in the spring of 1990 GE was dropped because it was unresponsive and its costs were too high.

The Westinghouse team includes Bendix, Honeywell, Link-CAE, Norden, and Singer-Librascope.

SQQ-89I was redesignated SQY-1 late in 1990.

See also SSATS, below.

◆ SQR-13

PADLOC (Passive-Active Detection and Localization), the first U.S. multi-array (and microcircuit) system, uses 2 arrays in separate domes. SQR-13 is incorporated in SQQ-23. PADLOC is a technique rather than a specific device; it was first tested using an SQS-29 and a submarine-type BQR-2B on board the destroyer *Glennon* in 1959, and PADLOC variants were proposed for use with SQS-26 during the 1960s.

◆ SQR-14/15

These very long range towed arrays are for surveillance. SQR-14 was designated the interim towed-array surveillance system (ITASS). SQR-15 was an improved version, intended as a backup to SOSUS. Instead, the U.S. Navy procured a longer-range SURTASS system. Both SQR-14 and -15 were produced by Gould. They are similar to, but not interchangeable with, BQR-15. Compared to SQR-18/19, SQR-14/15 use much longer arrays and operate at either much lower frequencies or with much narrower beamwidths.

The first SQR-14 was produced under the FY68 program. Tests were run in the early 1970s, and systems upgraded to SQR-15 configuration in 1974. SQR-14 was manufactured by Chesapeake Instrument Co. Six operational SQR-14As were bought under the FY72 program, after 1969 tests with a Tuba array. This 480-ft array could be towed by a destroyer, a frigate, a minesweeper, or a chartered commercial ship. Further versions were proposed: SQR-14B (1200 ft) for strategic and broad-area surveillance, and SQR-14C (525 ft) for surface escort. They all used 3-in-diameter modules, and all were speed-limited. SQR-15 was bought instead of SQR-14B, and SQR-18/19 in place of SQR-14C. There was also a proposed interim towed-array system, ITASS (3 in × 490 ft low-cost array, with better self-noise characteristics, but cumbersome handling gear, ca. 1973). SQR-14 is no longer in service.

Gould bought Chesapeake Instrument in 1975 and manufactured 6 SQR-15s (the last under the FY78 program) and 1 trainer. The first were aboard FFs 1037 and 1038 in 1975, and then 6 were carried by FF 1040-class frigates. One unit was lost in 1983 (when a Soviet Victor-III-class submarine cut through the tow cable with her propeller). The arrays were removed from their original platforms in 1983/84 and moved onto new ones (*Spruance*-class destroyers, 3 on each coast). SQR-15 electronics are carried in a van, for cross-decking. The OA-8705/SQR-15 array consists of 1 DT-541 (3 in × 29 ft) and 4 DT-540 (each 3 in × 29 ft, consisting of 6 ceramic elements) hydrophones, plus pressure transducers, 2 VIMs, and a drogue.

SQR-16 was an unsuccessful improved version of SQR-15, using a Gould wet end; only 1 was made.

◆ SQR-17

This family of shipboard sonar processors evolved from the SQS-54 LAMPS-I processor. SQR-17(V)1 is a 4-channel sonobuoy processor for the LAMPS-I, working with LOFAR, active, and BT buoys. SQR-17 can also process data from buoys dropped over the side of a ship, and also from a towed array (SQR-18). Acoustic data are displayed in either A- or B-scan and also in standard hard-copy form (e.g., LOFARgrams). The standard main console has 3 screens, a central 19-in acoustic-data display (for LOFARgrams) flanked by two 9-in screens for menu prompts, selection of operating mode, and monitoring of the status of multiple sensors. SQR-17(V)2 is an upgraded version to process towed-array data via an interface kit. The latter includes a digital multiplexer encoder/decoder (DMED) that converts the 32 channels of towed-array data, plus own-ship course,

speed, and track bearing, into high-density digital format for tape recording. SQR-17(V)3 adds frequency domain adaptive line enhancement (FDALE), an adaptive filter that makes weak lines more detectable within broad-band noise. FDALE was the first adaptive line enhancer in a fleet ASW processor. All of these systems were followed by SQR-17A(V)1 and (V)2, which add more sophisticated sonobuoy capabilities: 8 LOFAR channels or 2 DIFAR/DICASS channels. These versions can process VLAD array buoy data. Adaptive line-enhancement software is embedded in the system, which can also conduct TMA (MATE/MLE).

Subsystems are the SKR-4 link receiver, AKT-22 link, ARR-75 sonobuoy receiver, and UYS-1 processor. In 1988 this system was being modified to include a torpedo-warning capability.

These systems, which equip every LAMPS ship, are all manufactured by Diagnostic Retrieval Systems (DRS), Inc.

As of about 1989, 97 SQR-17s had been procured for shipboard use, and 16 were being procured for Mobile Inshore Undersea Warfare units. SQR-17 is to be modified for torpedo warning.

◆ SQR-18

The interim escort towed-array surveillance system (IETASS) was developed under the escort towed-array sensor (ETAS) program. SQR-18 was conceived as a simpler alternative to

SQR-18 broad-band display, with waterfall (for target motion in bearing) at right. (EDO)

SQR-18 LOFAR and ALI display. (EDO)

SQR-14/15. Work began under the FY68 program. One Patterson experimental array (PEA) was bought in FY72, leading to a specific operational requirement in FY73. IETASS was tested on board *Knox*-class frigates and a minesweeper, leading to the ETAS (program established FY75) and then to the TACTASS (tactical towed-array sonar) programs. Contracts for 2 IETASSs were awarded in August 1974. In FY80, 12 were retrofitted into *Knox*-class frigates, 4 more following in FY81.

The original SQR-18 was towed at depths of up to 366 m, at the end of a 1706-m cable. SQR-18A was the original production version, towed from an SQS-35 fish at the end of a 1524-m cable. SQR-18A(V)1 is an improved version deployed on board *Knox*-class frigates, towed from their SQS-35 VDS fishes on a 730-m cable. A modified version, SQR-18A(V)2, which does not require a sonar fish, uses a special depressor and a 5300-ft cable. SQR-18A(V)2 is towed by those *Knox*-class frigates that were never fitted with VDSs and by some *Perry*-class frigates. SQR-18(V)2 uses the same array-handling system, OK-410, as does SQR-19. The array itself consists of 32 vibration-isolated hydrophones (8 modular hydrophone sections), with preamplifiers in the fish; it is 730 ft long and 3.25 in in diameter. SQR-18 is towed at depths up to 366 m on a 1706-m cable.

SQR-18A(V)2 can use an EDO-developed short-scope tow, an alternative to a critical-angle tow requiring much less towing cable. The longer critical-angle tow is generally needed to isolate the noise of the towing ship from the array. However, EDO developed an own-ship noise canceler that can subtract the measured self-noise of the towing ship from the output of the array. The array is held down by a special depressor, a low-drag winged body with a V-tail and trailing-edge flaps on the tail fins, weighing 265 lb. The array passes through the depressor shell, for easy handling. This device was tested at sea in July 1981 on board the research vessel *Athena*, a former fast motor gunboat, at up to 34 kt, and then on board the surface-effect craft JEFF-A in August 1981 (at over 40 kt).

Late in 1981 the upgraded SQR-18A entered service. The 800-ft array consists of an 8-module acoustic aperture, vibration-isolation modules, a tow cable, and a rope drogue. The upgraded version enjoys better flow-noise damping, is more rugged, and suffers from less self-noise. Given the modular design of the array, 1 section can be replaced if it fails (a ship can carry spare modules); formerly, the entire array had to be replaced.

SQR-18As have been fitted with EDO's ALICE (adaptive line canceler and enhancer), consisting of an SQR-18A embedded post-beam-former interference canceler (EPIC) and an SQR-17 adaptive line enhancer (ALE). EPIC cancels a companion ship's sound so that submarines can be detected when a towed-array ship is escorting a very noisy ship. The engineering-development model was completed in February 1982.

SQR-18 entered service only 5 yr after initial demonstration and suffered from unreliability. Compared to the original SQR-18, SRQ-18A, the production version, has a low-noise array, an interference canceler, and an improved tracker. Production began in 1978, and an improvement program began in April 1981. The Dutch (2) and Japanese (6) navies have bought this system.

Produced by EDO, and also now manufactured by Gould, SQR-18 was initially to have been replaced altogether by the superior SQR-19; but development continued as insurance against any problems in the -19 program, and the -18 is now an alternative standard.

SQR-18 was first tested on board USS *Moinester* in 1975; -18A was tested in 1978. The initial results were that -18 was effective (but unreliable) in the first CZ, and that -18A corrected the demonstrated deficiencies. Only 2 SQR-18s were built, virtually all arrays being SQR-18A.

The newest projected version, SQR-18A(V)3, will use the EDO AMSP parallel processor.

Unlike SQR-19, SQR-18A has never used a standard nomenclature beam-former or processor. Instead it uses a 2-screen Diagnostic/Retrieval unit related to SQR-17. Inboard electronics consist of a signal conditioner, a digitizer, and a signal processor, for both narrow- and broad-band. SQR-18A can operate

in both broad- and narrow-band simultaneously, tracking by means of an automatically stabilized tracker beam and automatic target-following circuits. All processed data are stored electronically; the system does not use LOFARgrams. Each display can show up to 4 LOFAR channels; the results of signal measurement (frequency and amplitude of tonals, harmonic ratio, and tag frequencies) are shown as alphanumerics.

◆ SQR-19

SQR-19 is the current standard U.S. Navy tactical towed array, generally installed as part of the SQQ-89 suite. Development was protracted, largely because of early failures in the processor (the "dry end"). SQR-19 automates many of the detection, classification, and contact-management functions performed manually in SQR-15 and -18. These features permit 2 operators and the sonar supervisor to detect contacts reliably even in high-density acoustic environments. Unlike SQR-18, SQR-19 does not require a fish or other depressor.

The 800-ft array is towed on a 5600-ft (3.25-in diameter) cable, at depths as great as 1200 ft, to achieve ranges that cover multiple CZs. This is a lengthened version of the original 490-ft (1700-lb) array, modified after experience in 1983 showed that it was necessary to go to much lower frequencies to meet the silencing of new Soviet submarines. The acoustic aperture was doubled in length (to 16 modules), and a fourth aperture (8 VLF modules) added. The other 3 apertures, which are nested, con-

Typical towed-array handling gear (OK-410/AN/SQR-19). (Gould)

The tube running down one side of the submarine *Olympia* houses a towed array; there is no space within the single hull for anything so massive. Such stowage in turn limits the maximum length of the array. (U.S. Navy)

sist of 8 acoustic modules (4 LF, 2 MF, 2 HF), each of which, about 40 ft long, consists of 48 equally spaced hydrophones. In addition to the acoustic aperture, the array includes separate heading, depth, and temperature modules (HDTMs) monitoring ambient water conditions and a telemetry drive module (TDM); and the array proper is isolated from the tow cable by 3 vibration-isolation modules. There is also a drogue. Each hydrophone module contains its own amplifier, and the data are multiplexed for transmission, by the towing cable, up to the towing ship.

SQR-19 uses 2 UYS-1 processors (spectrum analyzers) and 2 OJ-452/UYQ-21 standard displays; typically its 2 display consoles are embedded in an SQQ-89. They are separated by an equipment rack holding a data terminal set (USQ-69) and a system control panel. A typical SQR-19 also incorporates 4 UYK-20 computers (later versions presumably have UYK-44s instead). Signals from the array pass through a standard signal conditioner and receiver, and the output of the 2 UYS-1 processors passes through an OL-190/UYQ-21 signal data processor (acoustic data converter) for display on the consoles.

Embedded programs filter data to reduce them to manageable proportions and provide computer-aided detection (presumably based on automatic line integration), visual alerts, optimum search display formats, special classification display formats, and special data-processing techniques. The 3 basic display formats are search, classification, and true bearing. The search format is a bearing-time record (waterfall) with some auxiliary frequency data (integrated lines). The classification display is a series of LOFARgrams. The true-bearing display is a series of bearing-vs.-time tracks, based on bearing cuts.

The system continuously monitors its own performance and can be reconfigured around failed elements without being taken out of service. Consequently, it has an estimated availability of 0.993 (which means all but 3.5 hr out of a typical 210 days during a year), with an MTBF better than 600 hr, a maximum fault-detection time of 1 min, and an MTTR of less than 20 min. The array itself is modular, for quick replacement of faulty elements, and it has an MTBF of better than 2000 hr.

The engineering-development contract for SQR-19 was awarded in December 1977, the first ship installation (DD 980) following in November 1981. The array was evaluated in November and December 1982, and approval for limited production was granted in March 1983. Full-scale production was approved on 26 December 1984 after the army had demonstrated a 2000-hr MTBF. SQR-19(2X), a lengthened array to detect lower-frequency tonals, was tested in FY87.

Versions:

- (V)1 two OJ-452(V)9 consoles, one OL-190(V)5
- (V)2 two OJ-452(V)8 consoles, one OL-190(V)4
- (V)3 two OJ-452(V)8 consoles, one OL-190(V)5

General Electric makes the onboard electronics ("dry end") and is responsible for system integration. Martin Marietta makes the "wet end" (array and handling gear) (Gould, the original manufacturer, sold its towed-array division in 1989). NUSC Newport is responsible for overall technical development.

◆ SQS-4/SQS-29 through -32/SQS-39 through -42/SQS-43 through -46/SQS-49 through -52

SQS-4, essentially a scaled-up version of the wartime QHB, was the first major U.S. LF sonar. The earliest type operated at 14 kHz with 3 alternative pulse widths: 6 msec (50 kW), 30 msec (30 kW), and 80 msec (5, later 10, kW). This version became Mod 4; later lower-frequency versions were Mod 1 (8 kHz), Mod 2 (10 kHz), and Mod 3 (12 kHz). The nominal range, against a submarine in the layer (and from a 15-kt destroyer), was 5500 yd (Mods 1 and 2) or 4500 yd (Mods 3 and 4). A target below the layer could be detected at about 1500 yd, and contact could generally be held out to 7500 yd (2500 yd below the layer). The range scales were originally 1, 2, and 5 kyd, but the demonstrated long-range performance led to recalibration (to 2/4/6/8 kyd, and then 1/2.5/5/10/15 kyd). The 48-stave transducer

(9 elements each) was scaled up from that of the earlier QHB (25.5 kHz) to produce beams of similar width (15×15 deg).

SQS-4 scans at 150 cycles/sec (900 rpm), compared to about 29 cycles/sec (1750 rpm) in the earlier QHB. This high scanning rate is achieved by scanning a rotor (with 16 contacts) at 3000 rpm; the outputs of each group of 8 staves go to separate left/right beam-forming networks. The outputs of the 2 networks differ in phase, and this difference can be used for target tracking, a technique called SSI (sector scan indicator). The staves are driven by 3 transmitter power amplifier cabinets (in groups of 16). Because of differences in wavelength, Mods 1 and 2 use a larger transducer than Mods 3 and 4; the transducer fits in a 145-in dome (a 100-in dome for Mods 3 and 4). There are 2 receiving channels, 1 video (on a PPI that can function in either ship-centered or target-centered format) and 1 audio. Later versions have 2 video channels. The video channel is considered preferable for tracking, the audio for target classification. Each channel requires its own scanner because the audio channel must be pointed at a target detected by video.

SQS-4 originally operated only in ODT mode; an RDT mode was added later in the 4 Mods. There are 2 modes: (i) search and (ii) maintenance of close contact (MCC), i.e., depressed beam mode (to keep contact on an approaching submarine). The outer 4 stave elements have search windings only; the next 2 above and below the center have both search and MCC windings; and the center element has 1 search and 2 MCC windings. In the MCC mode, the upper 3 MCC windings are energized. The lower 3 MCC windings are used for depth-finding. The sonar can transmit in either search, MCC, or depth-finding mode and can receive in search or MCC mode. The combination of 2 MCC circuits is DMCC (dual MCC).

An associated device, SQR-8 (tested in 1955) used the MCC/DMCC windings to measure the target's depth. It introduced a variable delay between the outputs of the lower stave elements (via their MCC windings). Each delay corresponded to an elevation angle (as in a phased-array radar), and the reception beam was scanned vertically between $+7.5$ and -45 deg. Given the target's depression angle and slant range as measured by the basic sonar, SQR-8 computed the target's depth automatically. The display was a quadrant of a spiral-scan PPI similar to the main video display.

MCAR (multiple-channel aural reception) was a modification for broader-beam reception to improve the capability against fast targets (3 beams 7.5 deg apart instead of the single 10 -deg receiving beam).

SQS-29 through -33 were modified SQS-4 Mods 1 through 4, respectively, with RDT and passive-search capability. Pulse lengths were 2, 7, 30, or 120 msec (4–50 kW), and range scales were 1, 2.5, 5, 10, 15, and 30 kyd. The effect of RDT was to increase the source level (by 1 account, from 117 to 133 dB) and thus to increase the range against a submarine in the layer by about 50%. Typical nominal ranges (for targets in the layer) were 7500 yd for SQS-29/30 and 6500 yd for SQS-31/32. SQS-29 could detect a target below the layer at about 2100 yd. In the RDT mode, the beam sweep could be set to cover 30 – 300 deg, oriented around the ship's bow. Later SQS-4 series sonars were modified for tribeam transmission with higher power; the nominal range was then 8000 yd. This series introduced ASPECT (acoustic short-pulse echo-classification technique: a burst of short steered pulses gives an indication of a target's shape) and built-in test equipment. In the passive mode, the outer $\frac{2}{3}$ of the PPI was used, and the sweep recycled at the rate used for the 5-kyd scale. For ASPECT, a transmit-beam control and programmer-recorder were added; the returned echoes were printed on a recorder chart. SQR-8 was eventually removed from most sonars of this type. At least some sonars in this series (mainly SQS-31 and -32) were modified for operation with SQA-10 VDS; the hull and VDS transducer could operate alternatively off the same stack. The VDS fish accommodated a full-size (48-stave) SQS-31 or -32 transducer or a half-size SQS-29 or -30 transducer.

SQS-39 through -42 were modifications of SQS-29/32 with

steered directional transmission (SDT) and MARK (maintainability and reliability kit). MARK entailed changes in the audio-frequency amplifier (preamp), the control indicator, the receiver-scanner, and the sonar transmitter cabinets. The maximum power was increased to 2.8 kW per channel (for a total of 134.4 kW).

SQS-43 through -46 were SQS-29B/C through -32B/C modified with MARK and SDT and capable of operating a VDS off the same sonar stack.

SQS-49 through -52 were SQS-4 Mods 1 through 4 with MARK.

SQS-4 was first tested in 1951, and it entered fleet service in 1954; 250 were made. The VDS version was first studied in 1960-61. Some SQS-4s were installed on board submarines, and many SQS-4s and modified versions were transferred to Allied navies. SQS-4 was made by Sangamo Electric; the later versions (SQS-39, -43, and -49 series) were modified by Philco-Ford.

SQS-5, an abortive alternative developed by EDO, was the basis of the Canadian SQS-503. SQS-5 introduced tribem transmission for faster search (than conventional RDT), operated at 7-15 kHz (pulse widths of 5, 14, 35 [60 kW], and 100 msec), and scanned at 100 cycles/sec (6000 cycles/min). The range scales were 2, 4, 6, and 8 kyd. This sonar was first tested in 1955.

SQS-4 sonars in the Taiwanese navy (and probably in others) have been replaced by Krupp-Atlas DSQS-21s. Sonars of this type reportedly survive in the following navies: Brazil (SQS-31 and -44 in FRAM II destroyers), Chile (SQS-40 in FRAM II destroyers), Greece (SQS-4 and -29 in FRAM II and *Fletcher*-class destroyers), Iran (SQS-29 in FRAM II destroyers, Italy (SQS-39 in the cruiser *Caio Duilio* and in *Impavido*-class destroyers), South Korea (SQS-29 series in FRAM II destroyers, SQS-4 in the surviving *Fletcher*), Turkey (SQS-29 in FRAM II *Sumner*-class destroyers and probably on board the *Robert H. Smith*-class destroyer minelayer), and Uruguay (SQS-29 on board the former *Dealey*, now *18 de Julio*). In many of these cases the identification of the sonar is by series rather than by precise type.

◆ SQS-10/11

These sonars were modernized postwar versions of the late-war QHB scanning sonar, the first scanning sonar in U.S. service. One QHB may survive; all known examples of this series are SQS-11s. SQS-10 was initially designated QHB-3; it was, in effect, a higher-frequency (20-kHz) SQS-4. SQS-11 was a 25.5-kHz equivalent. SQS-10 produced 6- (50 kW), 30- (10 kW), and 80- (3 kW) msec pulses, scanning at 150 cycles/sec with a 19-deg beam (range scales, respectively, were 1000, 3000, and 6000 yd). SQS-10A had a capacitor to provide a peak power of 30 kW at a pulse width of 35 msec. Alternative pulse widths: 7, 35, 100 msec. SQS-11A was analogous to -10A, also with the boost capacitor. Typical SQS-11A performance was 1600 yd/800 yd for targets in/below the layer (probability of detection 0.25) at 15 kt, and 1300/800 yd at 18 kt. These sonars were specified for U.S. destroyers and frigates in the mid-1950s, to replace QHBs installed from about 1950 on. SQS-4 was generally used instead.

SQS-11 seems to have been revived in the late 1960s, presumably in modernized form. From then into the 1970s it was installed on board the Japanese target-service ship *Azuma*, the Thai *Cannon*-class escort *Pin Klao*, and the Turkish *Berk*-class frigates. The Canadian *St. Laurent* group of destroyers all originally had SQS-10 or SQS-10/11 short-range scanning sonars in addition to their longer-range SQS-503s and their SQS-502 attack and -501 bottom-search sonars. SQS-10/11's range corresponded roughly to that of SQS-502. These sonars survive on board the *St. Laurents* and Improved *St. Laurents* (modified *Restigouches*). These ships also have the SQS-504 VDS. These ships were to have been fitted with SQS-505, but that has not yet been done.

◆ SQS-17

A scanning sonar for small ships, SQS-17 was conceived in 1954 as a searchlight sonar to replace QCU for ships such as the 173-ft PC. Although the U.S. Navy used only a few (possibly

only 2), SQS-17 was widely exported (see below) and was manufactured under license in France. SQS-17 was the first modern sonar manufactured in France, and experience with it led directly to the modern French scanning sonars. It operated at 12, 13, and 14 kHz with 16-, 35-, and 60-msec pulses (peak power of 1-6, 22, or 30 kW; source level of 134 dB) and used a 24-stave, 19-in-diameter array (originally using crystal transducers) comparable in size to that of SQS-31 (with a 100-in dome). SQS-17 was simpler than the SQS-4 series; the transducer elements were packaged together in such a way that the beam could not be elevated electronically. SQS-17 was an ODT sonar, although an RDT version was tested about 1957-58. The beam-former rotor tapped 8 staves, rather than 16 as in SQS-4. The scan rate was about 3500 rpm. SQS-17 was developed by EDO, and SQS-35 was conceived as an SQS-17 transducer in an SQA-13 VDS fish. Versions: SQS-17A and -17B which differed slightly in frequency.

Applications include: Chile (PC 1638 class), France (*Commandante Rivière* class, some of which were transferred to Uruguay), Iran (PF 103-class corvettes), Philippines (*Cannon*-class escorts and *Auk*-class corvettes), Portugal (*Commandante Rivière* class), Taiwan (*Auk*-class corvettes), Thailand (*Tacoma*-class frigates and PF 103-class corvettes), and Turkey (PC 1638 and PGM 71 classes). This sonar was installed on board Iranian PGM 71-class gunboats (now lost) and was probably installed on board exported World War II-era PCs modernized in the 1960s with fixed Mk 32 tubes.

◆ SQS-23/SQ-23/PAIR/PADLOC

SQS-23 was the LF replacement for SQS-4, associated with the ASROC stand-off weapon. SQS-23 was first installed in 1958 both in FRAM-I destroyers and in new construction, and it was also built under license in Italy and in Japan.

SQS-23 was the "reliable 10,000 yd sonar" specified for ASROC ships designed in the late 1950s. It is currently credited with a maximum range of 14-15 kyd under ideal conditions; the LORA version has a limited CZ capability (probably only in the Mediterranean).

Base frequencies are 4.5, 5, and 5.5 kHz; and the operating frequency can be varied around a base frequency to limit inter-

SQS-23 installed as a bow dome, USS *Barry*, 1959. This ship was the test installation. (U.S. Naval Institute)

ship interference. Pulse lengths are 2 (later 5), 30, and 120 msec, with range scales of 1, 2.5, 5, 10, 20, and 40 kyd. The mechanical commutator scans at 150 cycles/sec. The cylindrical array consists of 48 staves, each containing 2 transducers, for a total of 96 channels; and the sonar beam can be depressed electronically. In the long-pulse, wide-sector RDT mode, SQS-23H transmits 60 kW for 4.3 sec. Current versions employ both fixed-frequency and FM-slide pulses.

A typical SQS-23 source level (in the initial version of the sonar) was 244 dB.

Signal modes: ODT, RDT, SDT (9.25-deg beam, on a bearing chosen by the sonar operator, using a separate transmit scanner, for target tracking), MCC (broadened vertical beam, used with any other mode except handkey), and handkey (uses 4 staves about 90 deg apart, for underwater CW communication). Typical operating modes are search (RDT), search-analyze (long-pulse SDT beam on operator's chosen bearing), attack-RDT (operator controls width of pulse sector and slaves sector bearing to CRT tracking cursor; this mode allows target tracking but allows operator to observe a broad area around the target); and attack-SDT (for the late phase of an attack, when the operator concentrates on the target).

Numerous SQS-23s have been modernized by the addition of Raytheon's solid-state transmitters (SSTs); see the entry for the Raytheon DE 1191 below.

The major reliability/maintainability improvement program was TRAM, for test, reliability, and maintenance. The transmitter was split into parallel A (stave elements 1, 2, 3, 8, and 9) and B (stave elements 4, 5, 6, 7, and 10) groups. Each transmitter cabinet drives 8 (out of a total of 48) staves. PME (performance monitoring equipment, an 83-track tape recorder) has been added.

There were also performance improvement programs:

—MIP, modest improvement program, reducing CRT clutter caused by background reverberation and providing an FM transmission mode.

—LORA, long-range addition, largely by self-noise reduction (e.g., a rubber dome) to give SQS-23 a CZ/BB capability (presumably in the Mediterranean) for Atlantic Fleet ships only.

Versions:

SQS-23 Original version operating at 5 kHz only, using 6 electronic cabinets (with 6 audio-frequency amplifiers AM-2077/SQS-23) for 96 channels. Special features, compared to earlier sonars, were RDT and electronic control of beam elevation and depression. One audio and 1 video channel. The transducer was TR-144. SQS-23 was equipped for dual MCC and depth determination (by electronic beam depression and elevation). There are 2 scanners: fast (738.8 rpm) and slow (54 or 13.5 rpm). These figures seem to apply to all versions of SQS-23 through -23C. Later scanners were redesigned for better reliability and maintainability and, presumably, also for the much higher scanning speed indicated above.

SQS-23A This version introduced multiple operating frequencies (4.5, 5.0, 5.5 kHz). Each operating frequency could be varied over ± 250 Hz. This version used piezoelectric rather than magnetostrictive transducer elements, and it incorporated automatic power-level control.

SQS-23B This version reverted to fixed-frequency (5 kHz) operation but introduced a steered beam transmission (SDT) mode in addition to RDT. It, therefore, needed a new oscillator-programmer (O-956/SQS-23B in place of O-844/SQS-23A and O-576/SQS-23).

SQS-23D Center frequencies 4.55, 5.05, and 5.55 kHz (380-Hz bandwidth in each case), with 48 channels. Modes: CW and 400-Hz FM slide (chirp) with 5-, 30-, and 120-msec pulses. 150-Hz video scanning rate. This version incorporated training, reliability, and maintainability improvements as described above. This version and its successors are capable of rotating-beam steered-directional transmission (TRAM). As in earlier versions, it uses 6 power amplifiers for its 6 cabinets

(AM-2077B). The oscillator-programmer is O-956B/SQS-23B. SQS-23D is SQS-23 with TRAM.

SQS-23E Characteristics match those of SQS-23D above, but the oscillator-programmer is O-956C. SQS-23E is SQS-23A with TRAM.

SQS-23F is SQS-23B with TRAM.

SQS-23G is SQS-23C with TRAM.

SQS-23H Characteristics match those of SQS-23D above, but this version employs a solid-state transmitter. Transmission is accomplished by 3 solid-state cabinets in place of 21 vacuum-tube cabinets and 10 motor generators. The transmitter uses solid-state linear amplifiers and has automatic fault localization. There are only 48 channels because each is capable of powering a complete stave (it took 2 channels per stave in earlier versions). The transducer is designated TR-225 (SQS-23D and -23E used a transducer assembly, not a transducer proper). The oscillator-programmer is O-956B, as in -23D. There are only 2 audio-frequency amplifiers (in this case, AM-6740/SQ) with 3 power-distribution transformers (rather than 6 amplifiers operating in parallel).

SQS-23J/K/L Solid-state versions comparable with SQS-23H. SQS-23J uses O-956C; -23K and -23L use O-956D.

SQQ-23 (PAIR, performance and integration refit) is a modified version that incorporates passive tracking by a second transducer and PADLOC (passive-active detection and localization). Compared to SQS-23, PAIR adds a second operator console, as well as built-in test equipment. Output is 160 kW for 160 msec in ODT mode and 60 kW for 5.6 sec in RDT mode at 4.3–5.7 kHz, using 48 channels (1 per stave rather than 2 per stave, as in SQS-23). SQQ-23A uses simplified solid-state equipment (3 solid-state cabinets for transmission rather than 21 vacuum-tube cabinets and 10 motor generators). SQQ-23 uses a rubber rather than a steel dome for better sonar transmission.

SQQ-23A has 2 separate domes, 60 ft apart, which give a 60-ft baseline for triangulation of noise sources. SQQ-23A was evaluated in FY71 and entered service in FY73. This version applies to the *C. F. Adams* and *Mahan* classes.

SQQ-23B (*Leahy* class, *Bainbridge*, and *Long Beach*) has a single dome in which the 2 transducers are 4 ft apart. Targets are detected by correlogram, as in PUFFS (BQG-4) and micro-PUFFS (see separate entry). The broadside coverage is about 60 deg. SQQ-23B was evaluated in FY77 and entered service in FY80.

All active U.S. SQS-23s were converted to SQQ-23; the last active example was an SQS-23H on board the *Tatnall* (DDG 19), which was scheduled for conversion to SQQ-23A under the FY89 program. SQS-23D survives on board *Forrest Sherman*-class gun destroyers in reserve. SQQ-23 is limited to U.S. ships; all foreign examples of the sonar are SQS-23s.

Current users (many with DE 1191 solid-state transmitters) are Australia (the *Adams* class: SQS-23F), Brazil (2 FRAM Is), Greece (SQS-23D on 6 FRAM Is, SQS-23 on 1 FRAM II DDR), Italy (SQS-23G in the *Vittorio Veneto*, SQS-23 in the *Andrea Doria*), Japan (SQS-23 in the *Amatzukaze*, the *Takatsuki* class, the *Yamgumo* class [some as OQS-3], and the auxiliaries *Akizuki* and *Teruzuki*; as OQS-3 in the *Haruna* and *Chikugo* classes), Korea (5 FRAM Is), Mexico (2 FRAM Is), Pakistan (SQS-23D in 4 FRAM Is), Spain (4 FRAM Is, replaced in 5 *Baleares*), Taiwan (12 FRAM Is, 2 *Gearing* FRAM IIs [DE 1191]), and Turkey (2 ex-*Carpenter*-class ships, 7 FRAM Is, 1 *Gearing* FRAM II).

◆ SQS-26/53

SQS-26 was the culmination of U.S. LF sonar development, operating at about 3.5 kHz. It receives at 1.5–4 kHz, in 4 bands (7 channels). Power output is 192 kW. Like the earlier and higher-frequency SQS-4 and SQS-23, SQS-26 scans its beam using a mechanical commutator, so it can track only 1 target at

Installation of an SQS-53 sonar dome. (U.S. Navy)

a time. The transducer is about 16 ft in diameter and 5½ ft high and weighs about 60,000 lb; the sonar dome is generally described as comparable in size to a 60-ft personnel boat. Each of 72 transducer staves consists of 8 elements, and the beam can be electronically elevated and depressed, both for stabilization and for BB and CZ operation. The sonar forms 72 beams (5 deg wide).

SQS-53 is the solid-state successor to SQS-26, using 1 version of the SQS-26 transducer. SQS-53 and SQS-26 are the current standard U.S. long-range sonars, the only active surface-ship types credited with BB and CZ capability (in the Atlantic as well as in the Mediterranean).

Feasibility studies began in 1955, and the prototype XN-1 model was installed in 1961; the engineering-development model (XN-2) was delivered for installation in the USS *Wilkinson* in November 1961, and the pilot production models were delivered in August 1962, for the *Bronstein* class. Three parallel versions were built: -26AX by General Electric, -26BX by EDO, and -26CX by General Electric. The contract for 12 SQS-26AXs was let in 1961. The contract to EDO for 16 SQS-26BXs followed in 1963, and a contract to GE for SQS-26CX followed in October 1964 (the first SQS-26CX entered service on board the *Knox* in 1969). SQS-26CX became the production standard. The AX and BX sonars were not altogether successful, and a series of major modifications was approved in January 1965. CX deliveries began in December 1967, and General Electric modified existing -26AX sonars to -26AXR standard. The sonar itself was approved for service use only in November 1968, after considerable difficulties, and for some years SQS-26 was not credited with being able to achieve its theoretical performance (SQS-23 often did better in service).

Major improvements included much higher power, a rubber (rather than steel) sonar dome, and more reliable electronics. By the mid-1970s, SQS-26 was reliably achieving the BB and CZ performance for which it had been designed.

The rubber dome was a very significant improvement, later extended to other sonars, such as SQS-23. A steel dome limits sonar performance by passing machinery and hull vibrational noise to sonar; by corroding (corrosion creates flow noise); by vibrating (flow causes the plating to vibrate); and by attenuating signals (through plating and structural framing). BuShips let a contract to B. F. Goodrich in June 1963 for the design, manufacture, and test of a prototype rubber window dome (steel dome, rubber window, SDRW). At that time it was the largest molded rubber part ever built: 36 ft long, 20.5 ft wide, 8 ft high, 9.2 tons. The prototype was installed on board the USS *Willis A. Lee* early in 1965 and tested for 2 yr. A follow-up contract for DE (later FF) 1040, DEG-1, and DE (FF) 1052/1078 domes

was let in June 1967, and the domes were approved for service use in September 1968. By late 1969 both Goodrich and Good-year were qualified producers, Goodrich winning the first production contract in June 1970. The dome is a wire-reinforced membrane, whose shape is maintained by internal pressurization. The first production dome was installed on board the USS *Bradley* (FF 1041), beginning in December 1971.

All SQS-26/53 sonars either have been or are being modified to incorporate Probe Alert. The Probe Alert modification provides 1-way acoustic communication to submerged submarines having Probe Alert receiving equipment. Under this mode, the sonar system is dedicated to the projection of encoded signals into the water. Probe Alert entails modifications to the A-scan console, the sequential timer, and the transmitter control unit. It was first delivered in 1986.

Probe Alert is the latest of several attempts to use SQS-26/53 for underwater communication.

Versions:

SQS-26AXR in CGN 35 (*Truxtun*), FF 1037 class, FF 1040/FFG 1 class, and FF 1098 (*Glover*). This modification restores the sonar power supply to its original configuration. It has 3 consoles (surface channel, A-scan, and target tracking) and 2 sonar-signal processors (for coded and CW signals). The transducer is TR-198. The first 2 were installed on board the USS *Garcia* and *Brumby*. The transducer in this version was TR-198.

SQS-26BX is in all *Belknap* class except *Belknap*, also in some FF 1040/FFG 1-class frigates. This is a DIMUS sonar with a beam-former. It has only a target-tracking console and 1 signal processor. The transducer is TR-203, consisting of 576 individual elements. Each element is 5.75 in × 23 in (8 × 8-in face) and weighs 50.5 lb.

SQS-26CX is in all *Knox* (FF 1052) -class frigates and in *California*-class cruisers and was the basis for SQS-53. It has 3 consoles (but different units than in -26AXR). The transducer is TR-313 (there was also an earlier TR-227A). TR-313 has 576 elements and is 16 ft diameter × 5 ft 9 in and weighs 60,000 lb; it has 576 barium-titanate elements. It is fixed in a ship's hull, but the modified TR-313A is mounted on a turntable capable of limited rotation. Like -26AXR, -26CX has 2 sonar-signal processors.

SQS-53A in *Belknap*, *Virginia*-class cruisers, and *Spruance* class. This sonar is a solid-state version of SQS-26CX (it uses the same transducer) with better signal processing (using a UYS-1 signal processor, UYK-20 computers, and UYQ-21 displays). It has a digital interface with the Mk 116 FCS. As in -26AXR and -26CX, there are 3 consoles (surface channel, A-scan, and target tracking) and 2 signal processors. Delivery began in October 1972.

SQS-53B Phase I of SQS-53 improvement program, for the *Spruance*, *Ticonderoga*, and, potentially, the *Kidd* class. Analog controls and displays of SQS-53A are replaced by standard navy digital components to permit integration with SQQ-89. This version provides the capability to detect, localize, and track submarines at long range in both active and passive modes. It incorporates multiple-target tracking and classification aids and reduces manning by 60%. Improvements include: reduced insidious degradation (to detect calibration and alignment drift in the display subsystem, which could occur without the operator's knowledge), improved data association (for detection, classification, and tracking of simultaneous multiple active and passive contacts), dedicated passive LOFAR (eliminates dependency on SQR-17 or -18 by providing a UYS-1 signal processor), improved reliability and maintainability, and improved fault location. SQS-53B introduces digitized broad-band (Unit 31) in place of an earlier analog device that was very unreliable.

SQS-53B (and probably earlier versions as well) is capable of ODT and variable-depression operation (3 modes of receiver processing: search, tracking, and SSI/TDI). It has 3 receiving modes: PPI, preformed beams, and SSI/TDI. The sonar can op-

erate in passive narrow-band and broad-band modes. Inboard electronics: 2 OJ-452(V)4/UYQ-21(V), 1 OL-190 signal processor, and 1 UYS-1 (analyzer-detecting set). As in earlier versions, there are separate signal processors for pulse and coded (FM slide) signals. The (V)1 version has OJ-452(V)8 consoles, the (V)2 version has OJ-452(V)9 consoles. This version uses a UYQ-69 digital display, and it is controlled by a UYK-20 computer. SQS-53B was technically evaluated on board the USS *Moosebrugger* (DD 980) in August and September 1982, and an associated narrow-band passive capability was successfully demonstrated in November 1982. The first new-construction installation is on board the *San Jacinto* (CG 56). Another was installed on board the USS *Spruance*, and SQS-53B will be retrofitted to other *Spruances* and earlier *Ticonderoga*-class missile cruisers during their regular overhauls. The initial (quick-reaction) SQS-53 improvement program began in 1975; it included the installation of wide-band elements under the FY78 program as well as SIMAS (UYQ-25). The formal SQS-53 improvement program (IP) began in September 1977, to ensure commonality with SQQ-28 and SQR-19. Hughes received a contract for 2 EDMs in June 1979, 1 for a land-based test site (FY81) and the other for a *Spruance*-class destroyer (FY82). Claimed reliability: 200-hr MTBF (the goal was 500 hr) and 30-min MTTR.

SQS-53C Phase II of the SQS-53 improvement program, first tested on board the USS *Stump* (DD 978): the engineering-development model was installed in August 1986, and the full-production model was tested March–October 1987. Characteristics include: improved active performance (partly because of higher power), multiple-target capability, automatic target tracking, and quick reaction time. *Arleigh Burke* (DDG 51)-class destroyers will be completed with SQS-53Cs, and these sonars will later be installed on board *Spruance*-class destroyers and *Ticonderoga*-class cruisers. Compared to SQS-53B, -53C has half the space and weight devoted to shipboard electronics, largely thanks to the use of SEM cards. The remaining 1960s electronic technology of the -53B is replaced by new standard digital equipment. SQS-53C uses UYS-1 to process both active and passive signals, UYK-44 to control the sonar and display, and UYQ-21 as its display. The transducer has greater power output and a wider bandwidth, with 1 amplifier per transducer element. The beam is stabilized in all active modes.

Reportedly, SQS-53C has a stealthy active mode. Presumably, that is similar in concept to stealthy radar operation (as SPS-503) secured by long-time pulse compression, i.e., by spreading the pulse over a wider range of frequencies (hence the significance of the sonar's wider bandwidth).

Versions: (V)1, (V)2, (V)3. They may use a modified transducer.

The standard displays of sonar data in the SQQ-89 system (in which SQS-53C is embedded) are being improved by the insertion of 2 Advanced Video Processors (manufactured by Diagnostic/Retrieval Systems) in each OJ-452/UYQ-21 display cabinet.

The unit cost of an SQS-53B was \$6.3 million in FY87, compared to \$3.4 million for SQS-53C.

◆ SQS-35/36/38

The standard U.S. independent VDS, found on board some *Knox*-class frigates, is now significant primarily as the depressor for SQR-18 towed arrays. SQS-35 operates at 13 kHz, with a peak power of 30 kW, and uses 12 preformed RDT beams and a total of 24 reception beams (the transducer has 24 staves). SQS-35V is a solid-state version.

This sonar, developed by EDO under a 1966 contract, was derived from SQS-17. SQS-35(J) is a version license-built in Japan (by NEC).

SQS-36 is a hull-mounted equivalent of SQS-35. SQS-38, which equips U.S. *Hamilton*-class coast guard cutters, is a solid-state version. It operates at 11.9, 13, and 14.1 kHz and has an MCC mode, the last 2 (lowest of 9) transducers on each of its

SQS-35 VDS fish. (U.S. Navy)

24 staves being depressed to turn the beam down when desired. Nominal range is 12,000 yd.

Current users:

SQS-35: Japanese *Shirane* class, *Takatsuki*-class destroyers, and *Minekumo*; 5 *Chikugo*-class escorts; Spanish *Baleares* class.

SQS-36: Italian *Pietro de Cristofaro* class (with SQS-35 IVDS), Japanese submarines (as SQS-36J), Norwegian *Oslo* and *Sleipner* classes (being replaced by French *Spherion*).

◆ SQS-54

The shipboard processor for the LAMPS-I helicopter (1969) is built by Diagnostic Retrieval Systems, Inc. The helicopter itself carries no sonobuoy processor, acting merely as a sonobuoy and torpedo-dropping platform and as a relay for acoustic data. Thus, the helicopter's effective range depends, not on its fuel capacity, but on its ability to transmit data back by digital link to the deploying or controlling ship. LAMPS-I ships, therefore, have characteristic data-link antennas as high as possible, for maximum range. SQS-54 evolved into SQR-17(V)1 (see above).

◆ SQS-55

This is a special HF (100-kHz) sonar developed and used by the Naval Coastal Systems Laboratory, Panama City, to track underwater objects at short range. It is a high-precision, short-range DIMUS sonar, using an acoustic lens to form an array of sixty 2×10 -deg beams. Pulse width is 1 or 2 msec; range scales are 300 and 600 m. Nominal power is quite high, 218 dB. SQS-55 probably dates from 1972.

◆ SQS-56 (DE-1160B)

The hull-mounted direct-path sonar of the *Perry* class is built by Raytheon. SQQ-23 was originally chosen for these ships. Then the Canadian SQS-505, whose performance was not much worse but whose cost was much less, was chosen. SQS-56 was conceived as private-venture, a solid-state duct sonar whose weight, performance, size, and cost would roughly match those of SQS-505. Engineering design was completed in October 1977. Production began in 1979, following tests in 1975 and then in 1978. An upgrade program is currently being formulated.

The sonar is entirely digital in both active and passive modes. Operation is at 5.6, 7.5, and 8.4 kHz (36 kW).

DE-1160B is the export version. DE-1160C provides more power (with an extra electronic cabinet). Spain has upgraded her DE-1160Bs to 1160C standards. DE-1164 is the corresponding VDS, which can be trailed at depths as great as 600 ft.

Spain designates the sonar being installed in the *Baleares*

SQS-56 transducer and its sonar dome.

class as SQS-56LF rather than DE-1160LF. It is being produced largely by Inisels, under license.

◆ SQS-58

See Raytheon's DE-1167 below.

◆ LAMPS

The U.S. Light Airborne Multi-Purpose System is carried by a helicopter. LAMPS is listed here because it is conceived as a direct extension of a surface ship, rather than as a stand-alone device. LAMPS was conceived primarily as a means of acquiring and then attacking CZ contacts. A ship cannot fire a weapon directly at such contacts because the CZ is too broad. LAMPS was, therefore, conceived as the Light Airborne ASW Vehicle (LAAV); it gained the multipurpose designation because its tasks soon extended to assistance in OTH-T and ASMD. However, it is primarily an ASW sensor.

In the case of LAMPS I (the SH-2F Seasprite helicopter), which is intended to operate within 50 nm of a ship (for about 1 hr), the acquisition sensors, the sonobuoys, read out their data directly to the ship, which commands the helicopter into position to attack. The requirement for shipboard processing amounts to a limitation to line-of-sight operation, i.e., first CZ. A LAMPS I helicopter monitors 4 sonobuoys simultaneously (it carries a total of 15), using a single ARR-75 receiver. It also carries an LN-66 radar, and the shipboard sonobuoy processor is SQS-54.

An SH-60B LAMPS III helicopter. The sonobuoy rack is on the side, above the empty torpedo rack, and the flat ESM arrays are in the nose. (Sikorsky)

LAMPS I is the redetection/prosecution sensor associated with the SQR-18A towed array.

LAMPS III (there was no LAMPS II), the SH-60B, carries its own sonobuoy processor (UYS-1) and, thus, can operate beyond the ship's line of sight, out to the second and third CZ (nominal radius of action is beyond 100 nm, with 2½-hr endurance). However, it, too, is intended primarily for direct operation from a ship's CIC, its sensors controlled by an acoustic-sensor operator (ASO) in the sonar room; a remote-radar operator (REMRO) in CIC (who receives the helicopter's radar output via data link, and who can directly control radar range and operating mode); an EW operator (EWO) in CIC; and the air-tactical control officer (ATACO). The helicopter carries a pilot; an airborne tactical officer (ATO), who takes over from the ATACO as directed (e.g., when the helicopter passes out of radio range); and a sensor operator (SO). The line-of-sight data link is duplexed for voice and digital data, with low sidelobes for ECCM.

LAMPS III carries 25 buoys (though 12 would be used on a typical mission), 2 ARR-75 receivers, and an APS-124 radar. LAMPS III is the redetection/prosecution sensor associated with the SQR-19 towed array.

In each case, the usual final attack sensor is an ASQ-81(V)2 MAD, whose output is read out on board the helicopter. LAMPS I can also use active buoys for final attack data; it carries a paper range recorder sufficient for 2 SSQ-47 omnidirectional buoys or, presumably, 1 SSQ-62 DICASS. The LAMPS I sonobuoy chart recorder (RO-114) is controlled by an ASA-26B box. Range limitations at low chart speed (1 hr for recording) are 50 yd mini-

The small radome on the lower mast platform of this Spanish *Perry*-class frigate (mast at right) houses the directional data link for her LAMPS III helicopter. LAMPS I uses a vertical omnidirectional antenna. (S. Terzibaschitsch)

mum and 15,000 maximum; at high chart speed (30 min), 50 and 7500 yd. In the SH-60B, the chart recorder, which is an attack aid, is replaced by a general-purpose UYS-1.

As modified for operations in the Persian Gulf, LAMPS I helicopters were fitted with AAQ-16 FLIRs, ALQ-144 IR jammers, ALE-39 decoy dispensers, and door-mounted M60 machine guns.

Both LAMPS types are subject to upgrade programs. The current LAMPS I upgrade (SH-2G) provides an on-board sonobuoy processor (UYS-503), a secure ship-to-helicopter or helicopter-to-helicopter data link, a 99-channel sonobuoy receiver, and a 1553B bus. The current data link is AKT-22(V)7. The ASN-150 tactical system can display acoustic, radar, MAD, FLIR, or tactical (PPI) data. Because the helicopter is fitted with a data bus, sensors can be installed in modular fashion. For example, the bus can accommodate a FLIR. In trials, it has also supported a Cormorant dipping sonar and, reportedly, a classified British minehunting system tried out in the Persian Gulf. The current ESM system is ALR-66(V)3.

The LAMPS III Block I upgrade (1987, beginning with Lot 9) includes provision for the Penguin missile and the Mk 50 torpedo, a 99-channel sonobuoy receiver (to replace the current 31-channel unit), the ARC-182 radio, and a 5-channel GPS receiver. The helicopter will also be able to receive and display images from Standoff Land Attack (SLAM) missiles, to guide them farther beyond the launching ship's horizon. A new 1553B bus supplements the existing 1553A.

Development of a Block II upgrade should begin in 1991. It will include the airborne LF sonar (ALFS) and an ISAR modification to the existing APS-124 radar. The UYS-2 processor will replace the current UYS-1. Block II will also include a secure UHF burst tactical exchange link, to transfer data either to a ship or to a LAMPS I or LAMPS III helicopter relieving a helicopter on station. Presumably, the new link will offer greater security, greater flexibility (helicopter-to-helicopter as well as helicopter-to-ship), and more bandwidth (to transmit ISAR images).

Ships are being fitted with a "I/III Switch" that allows them to operate or to monitor either type of LAMPS helicopter.

LAMPS III incorporates an acoustic target tracker (ATT) developed by IBM to automate the manual tracking process of the past. Past sonobuoy tracking was based on bearing fixes generated by pairs of buoys and on the tacit assumption that the submarine was not maneuvering. IBM's goal was to reduce localization time and the operator's localization work load by 50%, and also to provide a real-time solution even if the submarine maneuvered.

In the manual system, contacts are manually updated as the submarine runs through the buoy field (ideally, down a lane of buoys). The bearings are converted into fixes that then become a course and speed determined by least-squares fit. Because the LAMPS III system was automated, IBM could add doppler information from the buoys, measuring a submarine's radial speed relative to them. The tracker maintains a real-time estimate of a target's position by filtering both frequency and bearing measurements from the buoys; there is no least-squares fit and, therefore, no need to assume straight-line motion. The algorithm begins with a crude estimate of submarine location based on bearings. Once that has been made, data are fed into parallel bearing and frequency trackers, which feed the target tracker.

Tests showed that the automated tracker could reach a consistent target-location solution very quickly, reaching attack criteria about twice as fast as the least-squares tracker and compensating automatically for the target's maneuvers. Often the least-squares tracker took as much as 10 min merely to come within 90 deg of the target's course, whereas the automated tracker could come within 15 deg in that time.

◆ AIS

Acoustic intercept system is a transient processor proposed in 1990 for all U.S. antisubmarine aircraft. Current airborne signal processors are intended to detect steady sounds by spectral anal-

ysis; AIS would seek transients such as the sounds of sudden maneuvers, sudden releases of steam, or torpedo ejection. This capability already exists on board submarines. In the case of aircraft it requires a second processor, which may add unacceptable weight. Funds were appropriated in the FY88/89 budget, and a draft RFP was issued; as of April 1990, a formal RFP was expected in May or June. The likely competitors are IBM/Allied Signal/AAC, Norden/Magnavox, and possibly Control Data.

◆ ALOFTS/LFAS

EDO's experimental Active Low-Frequency Towed Sonar was first tested in 1983. It is interesting as a harbinger of future LF systems. EDO used a standard 13/7-kHz fish carrying a flexensional transducer, and a multiline towed array was used as receiver. The system was tried on board a Second Fleet ship (using a single-line array) about 1984, then revived by NUSC New London in 1986 (with the 3-line array).

The projected Low-Frequency Array Sonar would be a production version of ALOFTS, perhaps using a larger fish, suitable for ships such as *Knox*-class frigates. A drawing of this system was displayed at the U.S. Navy League show in 1989.

See also SSATS/LFA/RMES below, and SQQ-89.

◆ BGMSS

EDO's Battle Group Multi-Static Sonar is a NUSC New London program. A drawing of the active element, a towed vertical body

Long-range active sonars must operate at low frequencies. One approach is to use a separate towed array or arrays as receivers, as in BGMSS (an experimental towed body is shown). The EDO/NUSC active low-frequency towed sonar (ALOFTS) is shown, with its cover removed. It uses flexensional transducers. The experimental system on board the USS *Glover*, LFAS (low-frequency active sonar), has used both a billboard active hull transducer and an EDO fish similar to that of ALOFTS (which has a lower source level but can be maneuvered into a more favorable position acoustically). In both cases the receiver was a multiline towed array, 3 SQR-18 arrays in vertical formation. At-sea tests began in 1988. One major discovery was that the array could be streamed and recovered easily without tangling. (EDO)

carrying an array of flextensional transducers, was displayed at the U.S. Navy League show in 1989. This type of system is one way of overcoming Soviet silencing.

An RFP was issued in January 1991. At that time the reported bidders were GE, Lockheed, Martin Marietta, Raytheon, TRW, and Westinghouse. Hughes was reportedly bidding only on the receiving system. The RFP may have called for only a combination of a pinger and a receiver suited to multiple receiver configurations because this system reportedly involved not only surface ships but also airplanes laying sonobuoy fields, as well as submarines. For the airplane, the passive buoys would act as receivers for echoes from a separate pinger. A submarine might receive echoes from a remote pinger, perhaps 1 on board a UUV and would share much the same processing problem. BGMSS has been called "son of SQY-1," a name that might imply the use of a receiver far from the pinger (SQY-1 would use a pinger plus an array receiver towed by the ship doing the pinging).

◆ SADS/MIDAS

SADS (Submarine Active Detection System) and MIDAS (Mine Detection and Avoidance System) are portions of the BSY-1 sonar suite.

SADS is reportedly an upgrade to the transmitter of the spherical bow sonar, to burn through jamming and other countermeasures. Reportedly, it and other current U.S. sonars employ both chirps (stepped frequency-variation) and continuously variable frequency pulses (slides) for a combination of target discrimination and reduced probability of interception. Such frequency variation within a pulse would be effective only in an environment free of multipath transmission, i.e., at long ranges. These waveforms offer much the same advantages as pulse compression in radar. SADS also integrates the spherical sonar with other special-purpose active sonars such as those used for ice and mine avoidance. Reportedly, too, SQS-53 shares some of the advanced waveforms and the power advantage of the SADS sonar.

Presumably, MIDAS is a relatively high frequency active minehunting sonar. To the extent that it is integrated with the bow sphere (and to the extent that the latter can operate over a wide range of frequencies), the sphere may act as a receiver for the secondary HF transmitter.

◆ SIMAS (UYQ-25)

Sonar In-Situ Mode Assessment System, a sonar performance predictor (essentially a very sophisticated ray-tracer) incorporated in SQS-53 and SQQ-89. It is particularly valuable for passive operation since it provides an operator with an estimate of CZ range and also with likely signal strength from various CZs (as well as from alternative signal paths, such as bottom or surface bounce). SIMAS is embedded (rather than separate) in SQQ-89(V)4 and later versions.

The original UYQ-25 of 1978 used a UYK-20X(V) computer, a USQ-69 data terminal, and a teleprinter. It was programmed by magnetic tape and weighed 1165 lb. The current UYQ-25A (1986) uses a DTC I desk-top computer (HP 9020) with 16- and 55-Mbyte disk drives and 0 or 1 spectrum analyzers (HP 3582A), a streaming tape drive (HP 9144A), a Thinkjet printer, and a color graphics terminal (HP 2627A). The same computer runs the Fleet Mission Program library. UYQ-25A(V)1 includes the spectrum analyzer and is used for SQR-18A(V) acoustic predictions and equipment-mode selection. UYQ-25A(V)2, for SQR-19 (part of SQQ-89), has no spectrum analyzer. UYQ-25A(V)3, with no spectrum analyzer, is for SQR-18(V).

◆ Optical Towed Array (AOTA)

In July 1989 Litton was awarded a navy contract to develop an all-optical towed array, i.e., one using optical fibers as its transducers. Acoustic signals cause minute changes in the length of the fibers and can be detected by interferometry. In theory, an all-optical array should support many more elements since different detectors can operate at many slightly different optical

frequencies (wavelengths). The results can be passed through an optical computer. If the signals from the different transducers are at different wavelengths, then the same processor may be able to handle them simultaneously. The program calls for a proof-of-concept array for laboratory and then sea tests, with delivery to the navy for an at-sea demonstration in a second phase. The entire contract is to be completed late in 1990. Litton developed the fiber-optic acoustic sensors and the all-optical telemetry involved. In this project, Litton is teamed with Bendix Oceanics.

◆ SMLTA

The Submarine Multi-Line Towed Array, now under development, is intended as successor to the very long single-line array (TB-12X/TB-29). Presumably SMLTA corresponds to the new surface-ship multiline arrays. SMLTA seems to have been first displayed in late 1990.

◆ SSATS/LFA/RMES

Surface-ship advanced tactical sonar is a generic term for the next-generation U.S. surface-ship sonar. It will probably be an active/passive suite, consisting of a multiline towed array (for greater gain/discrimination) and an LF transmitter, probably in the hull; there will probably also be a hull receiving array. The towed array will be the primary receiver for the LF pinger. For a time this sonar, under preliminary design by Martin Marietta, was associated with the U.S. FFX next-generation escort project.

LFA is the LF active test array, installed in FY88 in the bow of the *Glover*, a 3-line SQR-18 being used for reception. This system was later described as an FY88 new start, in collaboration with Britain, which will furnish a test ship and the instrumentation. The goal is a shallow-water (presumably continental-shelf) capability. Canada may join this program.

RMES is the Gould reconfigurable multiline towed-array evaluation system (contract awarded April 1987), a means of testing future towed-array configurations. Parallel lines of arrays provide increased gain without the geometric distortion associated with a single very long array and can also help solve the left-right ambiguity problem. However, it is not clear that these arrays can easily be handled at sea: hence the need for a test device.

Gould is supplying both the wet end (including a tow body) and the shipboard processor/beam-former.

See also SQQ-89 (improved).

◆ SURTASS (UQQ-2)

See the Surveillance and Control section.

◆ TARP

Towed-Array Range Processor is a term that apparently applies both to a form of signal processing and to a new long array used for passive ranging. In principle, an array either can be used as 1 leg of a triangulation device (the hull or bow array forming the other) or can be divided into elements and those elements used for triangulation. During FY87 a TARP model (presumably a processor using an existing array) was developed for at-sea testing, and a developmental TARP array was scheduled for tests during FY89. TARP is part of BQQ-5E, which is described officially as a quantum improvement in long-range detection and localization.

TARP system-processing capabilities were reduced and full vernier and TMA capability delayed because of reductions in FY88 funding.

◆ Towed Bodies (TB)

This series includes both towed arrays and other towed bodies:

TB-1/2/3/4/5 TB-1 is the towed body for the SQA-10A sonar hoist (on board FRAM II destroyers, carrying the VDS array associated with versions of the SQS-4 sonar), 1961: approx. 11 ft 10 in × 5 ft 5 in × 5 ft 5 in. The transducer inside is stabilized

so that it remains horizontal if the body pitches, and it can be prevented from pivoting. The body is free-flooding. There is also a TB-1A version. TB-1B is 142 × 48 (high) × 39 in and weighs about 6000 lb. Cable length is typically 600 ft. TB-2 is a version of TB-1 for the TR-170 or TR-170A (TB-2A) transducer. TB-3 carries the TR-171 transducer, TB-4 the TR-188, and TB-5 the TR-189. Some of these towed bodies remain in service in foreign navies.

TB-6 Towed submarine radio buoy for SSBN 608 class and later strategic submarines, for the BRA-8 radio antenna (1963).

TB-8 Towed submarine radio buoy for BRC-5 LF loop antenna and transceiver (54 × 57 × 16 in), 1969.

TB-9 Towed submarine radio buoy for BRA-8A radio antenna (122 × 41 × 65.062 in, 1000 lb), made by ITT Federal Laboratories, 1966. It is similar to, but not interchangeable with, TB-6/BRA-8. It has been modified to give external access to the pressure transducer.

TB-10 Towed body for SQS-35 sonar (97.5 × 26 × 58.5 in, 3000 lb).

TB-12 Array for BQH-4 (see separate entry).

TB-12X New long thin array. It is *not* related to TB-12. See entry below. See TB-29, below.

TB-13 Rope stabilizer (50 ft long, 2-in diameter) for SQR-15 array (OA-8705/SQR-15), operating at 2–15 kt.

TB-14 Towed body of the SLQ-25 countermeasure.

TB-15 Submarine towed loop-antenna housing for BRA-8C radio (1974). Dimensions: 122 × 65 × 41 in (1200 lb). Similar to TB-9/BRA-8A but not mechanically interchangeable.

TB-16 Submarine towed array (see below).

TB-17 Spears submarine towed radio-antenna housing, for the receiver group OR-197/BRR-6. Dimensions: 90 × 36 × 41 in (1400 lb).

TB-18 Spears submarine towed radio-antenna housing, for the OE-306/BRR antenna group, carrying it nearly to the surface. Similar to the larger TB-17/BRR-6. Dimensions: 97.5 × 30.0 × 37.88 in (1225 lb).

TB-19 ALQ-141 helicopter mine-countermeasure towed sonar body.

TB-20 Submarine towed array (see below).

TB-21 Towed body for the SLQ-33 countermeasure.

TB-22 Sonar body for the AQS-14 helicopter-towed minehunting sonar.

TB-23 Thin-line towed array (see separate entry).

TB-24 A Mk 6(B) Mod 5 acoustic device in SLQ-37 mine countermeasures.

TB-25 A Mk 4(V) acoustic device in SLQ-37 mine countermeasures.

TB-26 A Mk 6(B) towed body in SLQ-37.

TB-27 A Mk 4(V) towed body in SLQ-37.

TB-28 BRR-7 towed radio antenna body, similar to TB-18.

TB-29 Long thin-line array (TB-12X); see separate entry.

◆ TB-12X/TB-29

This new, long, thin, submarine towed array is part of BQQ-5E and BSY-2. The designation does not indicate a new version of an earlier TB-12; rather, it seems to mean an array with an acoustic aperture 12 times as long as that of TB-16, and reportedly it is more than 3 times the length of TB-23. That probably means about 2500 ft (12 TB-16s would be 2880 ft long, but the

TB-16 acoustic aperture must be shorter than the total array length). Compared to TB-23, TB-12X is credited with improved passive detection and ranging and improved LF performance; it is described officially as a quantum improvement in long-range detection and localization.

TB-12X is part of BQQ-5E, superseding the TB-23 of BQQ-5D, on board *Los Angeles*- and *Ohio*-class submarines. In the new *Seawolf*, TB-12X will be combined with the shorter TB-16D.

Preliminary sea trials were run during FY89, when the final TB-12X specification was drawn up. A full-scale development contract was awarded in the second quarter of 1990, with sea trials in October 1990 and October 1991, and technical and operational evaluation scheduled for 1993.

The TB-29 designation appears to have been applied to the new 12X array late in 1990; it may still be unofficial. TB-23 was the earlier 4X thin-line array.

◆ TB-16/BQ

This submarine towed array is a component of BQQ-5; it can also be used as a stand-alone device. The designation was assigned in 1974. Typically, TB-16 is stowed in a tube running outside the pressure hull, the reel, cable, and winch being located in the forward main ballast tank. The array is streamed out of a tube leading from the port horizontal stabilizer. This installation was designed for SSN 637-class submarines, the early 688s being fitted with a permanently streamed (clip-on) array. The 688s were later provided with reelable arrays using tube stowage, operational experience having shown that the fixed array could be damaged during high-speed runs.

The original TB-16 acoustic array is 240 ft long and 3.5 in in diameter (1300 lb), towed on a 2600-ft cable (0.37-in diameter). It consists of 2 vibration-isolation modules (VIM), 1 transverse VIM, 1 sensor module, 5 acoustic modules (presumably of varying frequencies) with a total of 50 hydrophones, and 1 array-stabilization module. Hydrophone signals are amplified, conditioned, and modulated, then frequency-multiplexed for transmission to the submarine via the tow cable. The modular design of the array allows for complete interchanging of acoustic module positions within the array, including the unique spare module, provided no 2 with the same channels (indicated by part number) are used in the same operating configuration, and proper channel cards are substituted in the LF receiver processing the signals transmitted by the array.

TB-16A (1403 lb with a 450-lb cable, 1982) is modified for reduced self-noise, so that the array can be towed at greater speed without loss of sensitivity, or can be towed at the same speed as TB-16 with greater sensitivity. Its tow cable is about 2600 ft long. TB-16B (1986) is a modified version embodying ECP 59 (engineering change proposal 59) for further reduced flow noise. In its case (and probably the cases of other versions) the acoustic module is 186 ft long. The current version is TB-16D, the chief improvement being a shift from analog to digital signal transmission. Compared to a thin-line array, the shorter but thicker TB-16 should suffer less self-noise at a given speed but should also be effective only at higher frequencies. In some cases it is being superseded by the longer and thinner TB-23, but BSY-2 incorporates both TB-16D and a long thin-line array (TB-12X).

TB-16 is the production version of TB-16(XN-1)/BQ developed under a 1973 contract. The array was originally made by Chesapeake Instrument Co., which was then taken over by Gould, and then by Martin Marietta, the current manufacturer. Gould received a contract for 24 TB-16s in August 1982 (for BQQ-5 and -6 installations), and late in 1982 the company received a contract to integrate this array and the mine detection-and-avoidance systems (MIDAS and SADS) into BQQ-5. In FY84 a total of 27 TB-16s were authorized (3-yr procurement). TB-16 is an improved version of the Tuba II (BQH-4) array, offering a much wider frequency range than the earlier nonretractable STASS (BQR-25). This retractable array was selected in preference to a proposed much longer nonreelable type, SITTAR (a 500-ft aperture on a 1000–2000-ft cable).

◆ TB-20/BQ

Hughes's developmental submarine thin-line towed array (1983) is presumably the loser in competition with TB-23. The array proper, 1500 ft long and 1 in in diameter, carrying 96 hydrophones, is towed on a 2500–5000-ft cable. Data are transmitted down the cable in pulse-code modulated (PCM) form. Array components: 4 vibration-isolation modules (VIM), 1 electronics module, 4 LF modules, 2 MF modules, 2 HF modules, 1 clock module, and 2 aft termination modules.

◆ TB-23/BQ

This thin-line submarine towed-array sonar has an overall length of 4000 ft (2450 lb); maximum diameter is 1.1 in, except 1.14 in at intermodule couplings, 1.15 in at VIMS, and 1.2 in at array-termination module. Total length includes the length of the tow cable, probably 2500 or 2600 ft (as in TB-20, above). The array, which is made by Bendix Oceanics, consists of 2 VIMS, 1 environmental module, 4 LF modules, 2 MF modules, and 2 HF modules, plus an array-stabilization module and an array-termination module. This array contains 98 hydrophones.

TB-23 was introduced in FY83 *Los Angeles*-class submarines. It was tested in 1987. Current plans call for this system to be installed not only in *Los Angeles* but also in *Ohio*- and *Sturgeon*- (SSN 637) class submarines. Development of the latter's thin-line handling equipment (TLHE) was completed in FY88.

◆ UUVs

This is DARPA's project to develop unmanned (autonomous) underwater vehicles, mainly for use from submarines. Two Scout vehicles are being built by the Charles Stark Draper Laboratory, for demonstration runs in 1990. Although the current design is too large (44-in diameter) to fit torpedo tubes, a later version might fit the 30-in tube planned for the new *Seawolf*.

DARPA is developing vehicles and subsystems for the Pathfinder, submarine escort/decoy, and UUV-deployed hydrophone array roles. Pathfinder is a semiautonomous mine-avoidance capability, the UUV guiding a submarine through a mine field. It is also designated MSS (mine-search system). Escort/decoy is a submarine simulator that will decoy the threat and communicate intruder information. It is designated TAS (tactical acoustic system). DARPA awarded the MSS contract to Lockheed in January 1990 and the TAS contract to Martin Marietta in February 1990. The third variant, the remote surveillance system (RSS), was not awarded and may be killed for the present. As of mid-1990, DARPA hoped to hand over UUV technology to the navy for full-scale development in October 1990.

NRL began the first U.S. UUV project, the 2460-kg UFSS (unmanned free-swimming submersible) in 1975, to test laminar flow. It also had a doppler sonar and some pattern-recognition artificial-intelligence, to permit it to find objects on the ocean floor. NOSC San Diego developed the 182-kg EAVE-West (experimental autonomous vehicle), with a side-looking sonar, a magnetic pipeline follower, and a fiber-optic communications link. The parallel EAVE-East project, conducted by the University of New Hampshire Marine Systems Engineering Laboratory (MSEL), was designed to inspect underwater structures and to map the underside of Arctic ice cover. Several EAVE-Easts were used together in a DARPA multiple autonomous undersea vehicle (MAUV) project, which was canceled in 1989. Since 1985 Martin Marietta has developed its own 9-m (29.5-ft) mobile undersea test device (MUST).

◆ EDO 610 Series/CWE-610

This LF (6-, 7-, or 8-kHz) hull sonar is for frigates and larger ships. 610 uses preformed 10-deg beams both for reception and, in directional-transmission modes, for transmission. Modes are ODT, search (120-deg sector), and attack (50-deg sector). Maximum instrumented range is 32 kyd, and 610 can measure target doppler up to 40 kt. There is also a passive display for long-range detection. Beam width is 10 deg vertical and horizontal, and range scales are 2, 4, 8, 16, and 32 kyd.

The 36-stave hull transducer is 1245 mm in diameter and 1067 mm high (weight 2500 kg).

This sonar is designed so that it can be used in conjunction with the EDO 700/701 VDS. An improved 610A appeared in 1972. EDO 610E is a solid-state version incorporating SQS-38 experience.

Development began in 1963, for the Royal Netherlands Navy, of the first EDO sonar designed specifically for a foreign customer. A prototype was completed in 1966; the first production model completed its sea trials in 1969. This work incorporated EDO's experience with SQS-26. Applications: Brazil (Vosper Mk 10 frigates have 610E; ASW ships also have EDO 700E VDS), Italy (*Audace* class; some export *Lupos* have 610E), Netherlands (*Tromp* and *Van Speijk* classes). In Dutch service this sonar is designated CWE-610. The Canadian SQS-505 sonar is derived partly from CWE-610. CWE-610 was conceived as a much lighter and much more compact alternative to the very heavy SQS-23.

◆ EDO 700/701/DDE-700

This VDS was developed in parallel with the 610-series hull sonar, also for the Royal Netherlands Navy; 700 can be used in combination with the 610. Model 700E is a solid-state version incorporating SQS-35(V) technology (1972). Dutch *Van Speijk*-class frigates modernized with EDO 610 hull sonars were also fitted with this VDS, designated PDE-700. The Brazilian Vosper-Thornycroft frigates are fitted with the related EDO 701 VDS. EDO 700/701 technology was incorporated in the U.S. SQS-35(V) sonar.

The 24-stave transducer is 495 mm in diameter (787 mm high) and weighs 397 kg. The hoist and towed body together weigh 8250 kg. Frequency is probably 13 kHz.

Users: Brazil, Japan (presumably MSA), and Indonesia (ships now transferred by the Netherlands).

◆ EDO 780 Series (780, 786, 796, 795, 7860, 7960, 7950)

This modular series of hull and variable-depth sonars ranges from a lightweight VDS (780) up to a large LF hull sonar (795/7950). Each model uses the same basic console, transmitter, receiver, and data-storage and control unit. Given this modularity, any hull sonar in the series could be supplemented by a VDS, or vice versa. The original EDO 780 was a small VDS; 786 was the same sonar in a hull-mounted version. 796 and 795 were lower-frequency hull sonars.

EDO's 7860, 7960, and 7950 are all combinations of a 13-kHz VDS and, respectively, a 786, 796, and 795 hull sonar.

The standard display has a dual CRT, and display data are all stored internally, so that alternative displays can be called up

Typical modern sonar displays, in this case from an EDO 780 series sonar. The passive search display is a waterfall. At right in the passive track classification display is a time-integrated LOFAR (a spectrogram). (EDO)

EDO/780-Series Characteristics

	MODEL			
	780	786	796	795
Frequency	11.9/13/14.1 kHz	11.9/13/14.1 kHz	6/7/8 kHz	4.3/5/5.7 kHz
Source Level (Higher Level was available as an option):				
SRDT	232 dB	226 dB	231 dB	232 dB
TRDT	226 dB	226 dB	225 dB	226 dB
DT	224–232 dB	218–226 dB	223–231 dB	224–232 dB
ODT	217 dB	217 dB	216 dB	217 dB
MCC	199 dB	201 dB	210 dB	210 dB
Weight:				
Inboard	2188 kg	2176 kg	2436 kg	2436 kg
Outboard	7300 kg	1365 kg	3045 kg	5000 kg

at will. Tracking is by ball-located cursor on a display. Alternative displays are: ray-path predictor; active detection (range vs. bearing); active search (6-ping history to make weak targets stand out visually); active track classification (sector scan range vs. bearing and target doppler side by side); passive search (bearing vs. time waterfall; either long-time for slow targets or short-time for fast ones); and passive track classification (bearing-deviation indication for high-accuracy tracking and target spectral analysis side by side). All of these displays show processed, rather than raw, video.

All sonars in the series have 24 preformed beams, and all employ 10-, 30-, and 60-msec CW pulses and 60-msec FM pulses. Each sonar provides its operator with the choice of 8 acoustic-intercept bands. Accuracy is $\frac{1}{2}\%$ of the range scale, 1 deg in active bearing, and 0.5 deg in passive bearing. Range scales are 2, 4, 8, and 16 kyd, with 32 kyd added in the 2 lower-frequency sonars.

For the 2 HF sonars, the passive band is 5.8–10.6 kHz; for the 2 lower-frequency sonars, it is 2.8–5 kHz.

The original EDO 780 was derived from the company's experience with SQS-35 and appeared in 1976; 780 is installed on board 4 Israeli *Sa'ar-II*-class missile boats, controlling light-weight torpedoes. EDO 786 (1979) is derived from EDO's experience with the corresponding hull sonar, SQS-38. 786 is installed on board Korean frigates; it replaces the SQS-42 on board Indonesian *Claud Jones*-class escorts. EDO 7867 and 7957 are improved versions of 786 and 795 (1984). EDO 796 (7 kHz) has been selected for the new Israeli *Sa'ar-V* class. It differs from earlier EDO sonars in using a standard Israeli console.

The EDO 780-series displays were based on experience with BQQ-5. Compared to SQS-56, they show more attention to passive detection, with waterfalls (time vs. bearing displays).

◆ EDO 787

This compact 7-kHz VDS uses the same fish as the 13-kHz EDO 780. The electronics are common to, and compatible with, Models 786, 795, and 796.

The transducer operates at 6, 7, or 8 kHz, with source levels as follows: ODT, 215 dB; DT, 219–226 dB; TRDT, 220 dB; SRDT, 226 dB. Pulse widths are 10-, 30-, or 60-msec CW, or 104-msec long FM (pulse-compressed). The active receiving bandwidth is 500 Hz, and the passive bandwidth is 2.8–5 kHz. The operator can specify 8 acoustic intercept bands. There are 24 preformed beams. Instrumented ranges are 2, 4, 8, 16, and 32 kyd. Accuracy: active range, $\frac{1}{2}\%$ of range; active bearing, 1 deg; passive bearing, 0.5 deg.

Transducer dimensions: diameter 22 in, height 31 in. Unlike most cylindrical transducers, 787 is not constructed of a series of vertical staves. Instead, square spot transducers are arranged in a spiral over its face. EDO claimed that this new transducer design was what made it possible to provide a 250-ton patrol boat with a useful LF sonar.

Model 787 was announced together with a new EDO Advanced Modular Signal Processor, which could be used by other 780-series sonars. That processor, in turn, was the basis for a

linear FM coherent signal processor that was expected to improve performance substantially in the face of noise or reverberation. Signals were linearly broken down into pulse compressed signals and displayed in a clutter-free computer-driven display.

◆ EDO 900/910

These units are underwater-object locators and mine-detecting sonars for submarines. The difference between the 2 models is that in Model 900 the scanning head is above its drive mechanism, whereas in Model 910 the scanning head is below; Model 910 is a 900 adapted as a minehunting sonar. Dimensions and the display (a 7-in ship-centered CRT) are identical. The signal is a continuously transmitted FM slide, which gives a clear audio presentation. The transducer is 368 mm in diameter.

This sonar was sold to Germany for use on board Type 206 submarines.

◆ EDO 1102/1105

This is a solid-state version of the old standard U.S. BQR-2B/BQS-4 suite for the Peruvian *Abtao* class (1976). It combines the original arrays (with a passive transducer 1244 mm in diameter and an active transducer 330 mm in diameter) and cabinets with new electronics. Visual display modes are bearing vs. time (waterfall), range vs. radial speed (doppler), and self-noise. In the passive surface-ship detection mode, processing prior to display shows ranges (computed, presumably, by TMA with automatic speed estimation by blade count) out to 30,000 yd and bearings accurate to within 0.5 deg. The first 2 sonars were fitted in chin domes, but they increased the submarines' draft too much, and the last pair received large bow domes above decks. The first 2 submarines were later refitted with above-decks domes.

◆ EDO 1110

Model 1110 is a flank sonar for submarines, consisting of a linear transducer array. 1110 is intended as an adjunct to existing sonar, combat, and fire-control systems. This sonar uses LF beam-preforming, split-beam correlation (for accurate pointing), and spectral analysis; and 1110 can track more than 15 targets simultaneously, using broad- and narrow-band processing interpolation. Selected targets can be assigned to "high quality" track processors for improved positional accuracy, and these tracks can be maintained even when targets cross the submarine's path (passing from the FOV of 1 array to the other). The operator initiates track by using a cursor at the console.

There are 2 high-resolution color displays, options including frequency vs. bearing and bearing vs. time.

This system appeared in 1985. EDO describes 1110 as based on operational experience in the U.S. and foreign navies, so the capabilities above may be typical of existing passive hull arrays.

This sonar was sold to an undisclosed foreign customer. It will be delivered during 1991.

(Above) EDO 1110 submarine flank-array sonar. (EDO)

◆ Micro-PUFFS/PASLAN/BQG-501

Sperry's passive ranger for submarines is a micro-circuited version of the earlier BQG series, using baffled hydrophone arrays. Because Micro-PUFFS employs 3 transducers along the hull, it is inherently much quicker than TMA; on the other hand, range is limited by the length of the baseline. PUFFS itself was developed by the U.S. Navy and by Sperry in 1956-60 (and Sperry produced 54 units in 1960-66). Micro-PUFFS was developed specifically for the Royal Australian Navy (1972-76), and in 1979 Sperry began work on a similar system for the Royal Navy. As BQG-501, Micro-PUFFS was incorporated in the Canadian *Oberon* upgrade program (SOUP), Micro-PUFFS electronics replacing that of the earlier Type 719 sonar. In the Canadian ships, Micro-PUFFS is visible in the form of 6 red-outlined soft patches along the sides of the upper casing (Stations 15 to 18a-19a, 64b to 69a, and 103 to 110, all port and starboard). This sonar was also installed on board the *Barb* (tested 1980).

The 3 hydrophones on each side of the submarine form 5 continuously processed preformed beams (5 beams per array); targets are tracked automatically. Ranging is by cross correlation of the same signal as received by the 3 arrays, the 2 time differences being converted into bearing and range data. The range solution is, therefore, both instantaneous and continuous. Each triplet of hydrophones covers a 150-deg sector. In an Australian *Oberon*, the hydrophones are 108 ft 9 in apart. Each hydrophone is a square array (5 staves, each carrying 5 spot hydrophones). Sperry estimated that the range error on a target directly abeam at 6000 yd would be about 2.5%, rising to about 11% 60 deg off the beam. The error would be about 5% at 12,000 yd (directly abeam).

Sperry claimed that Micro-PUFFS could more efficiently reject background noise because it used correlation and preformed-beam techniques. Early sea experience suggested that MTBF might be as great as 3600 hr, with 30 min (or less) MTTR.

PASLAN (Passive Ranger) was a modified Micro-PUFFS delivered to the U.S. Navy in 1979 and tested on board the nuclear submarine *Haddock* from July 1979. The arrays are larger than

MicroPUFFS arrays. (Sperry)

MicroPUFFS display. The CRT shows 2 correlograms, 1 for each pair of adjacent arrays on 1 side. The upper line shows 150 deg of bearing on the starboard side; the lower, 150 deg on the port side. Targets appear on 1 or the other, and a control stick can be used to position a cursor on the target. When the operator aligns the peak of a correlogram with 3 dots on the display and presses a button, the system begins to track the target automatically in bearing. The operator can begin to track automatically in range when the peaks of the 2 correlograms are aligned (i.e., when triangulating on the same target). Contact data are displayed in the upper right-hand side of the panel, including true bearing, relative bearing, bearing rate, and range. Target's course and speed are indicated continuously through TMA. (Sperry)

those of Micro-PUFFS, and the system can track quieter targets at greater ranges. Presumably, PASRAN was an alternative to WAA.

◆ Raytheon DE 1160 Series

As of 1988, over 100 of these Raytheon export sonars were in service. All share common computer hardware and software, common displays, common transmitter amplifiers and power supplies, common circuit cards, and common interface units. Unit cost is \$3.5 to \$4.5 million. In 1988 DE 1167 cost \$2 million each.

DE 1164 fish shown after it had been streamed and recovered by the Italian frigate *Maestrale*, March 1982. (Raytheon)

DE 1160 is a medium-range direct-path sonar for corvettes and larger ships. See the entry below for DE 1160B details.

DE 1160C is the standard U.S. SQS-56 frigate sonar (see above). 1160C weighs 12,800 lb, compared to 11,600 for DE 1160B; and peak power is 90 kW (average 10 kW) rather than 30 kW (10 kW average). Both B and C have the same transducer and the same sonar receiver, but DE 1160C adds an additional transmitter (unit 13) and a dummy load (unit 14). Both sonars provide simultaneous active and passive detection. This is the sonar of the Spanish *Descubierta* and *Perry* classes.

DE 1160LF is a larger LF version, in the Italian carrier *Giuseppe Garibaldi*.

DE 1163 is a VDS version of DE 1160. Peak power is 35 kW (average 7 kW).

DE 1164 is an integrated hull-mounted VDS variant, combining DE 1160 and DE 1163. In hull sonar form 1164 equips the new *Animoso*-class destroyers. In VDS form, 1164 is installed on board Italian *Maestrale*-class missile frigates. This sonar also equips the *Alpine* class. Peak power is 35 kW (average 7 kW).

DE 1165 (see entry below) is an integrated submarine sonar.

DE 1167 is the latest version, smaller and lighter for fast patrol craft and similar types. 1167 exists both in hull and in VDS versions (and also in a hull/VDS combination version). Total weight of the hull version, including the dome, is 1460 kg; total weight of the VDS version is 10,260 kg. There is also an LF version for larger ships that cannot accommodate DE 1160 B/C. DE 1167 (MOD) is used to modernize existing SQS-23s: the receiver and console and a new 48-kW solid-state transmitter (SST) are added to the existing dome and transducer, adding a minimum of 10 dB in performance.

DE 1191 is a new solid-state transmitter suitable for SQS-23 modernization (see entry below).

◆ Raytheon DE 1160B

Raytheon's hull sonar has an optional VDS extension. 1160B operates on 6.7, 7.5, and 8.4 kHz, with a bandwidth of 400 Hz (FM or CW). The beam can be depressed/elevated at 12.5 or 25 deg. Operating modes (active) are ODT (5.0–160 msec pulses, source level 218 dB), Single RDT (5.0–2180 msec pulses, source level 232 dB, over a 20–120 deg sector), Triple RDT (5.0–1940 msec pulses, 227 dB), and wide (5–700 msec pulses, 30–120 deg sector, 225 dB). Reception modes (600-Hz bandwidth) are search (36 fixed beams, 12.5-deg depression/elevation, 2-deg resolution in azimuth, 2-yd resolution in range on 2.5-kyd scale, 16-yd resolution at 20 kyd) and tracking (2 steered-independent 20-deg beams, range gates 625 and 1250 yd using a sector-scan indicator).

The standard dual console of a DE 1160 sonar. The lower screen is a dual B-scan (range vs. bearing). (Raytheon)

and target doppler indication; one 14-deg independent audio beam, accuracy 0.5 deg in azimuth, 1.1 yd in range, and 2 kt in doppler). The sector-scan indicator (SSI) and target doppler indicator (TDI) are target-following aids, respectively comparing the phase differences on either side of a beam and showing target doppler.

There is also a passive mode using 18 fixed beams (18×21 deg) at 3–6 kHz, with audio on 1 selected beam. This mode uses a DIMUS processor (signals are clipped, processed digitally, and then filtered through short-term averaged and long-term averaged smoothing filters). The displays are all B-scans; active track data are presented on an expanded B-scan (20 deg in bearing $\times$ 625 or 1250 yd), and both long- and short-term averaged data can be presented separately, in waterfall form.

Peak power is 30 kW (7.2 kW average). The hull transducer is 121.9 cm (diameter) $\times$ 96.5 cm (weight 2268 kg). Total system weight is 5302 kg.

DE 1160/SQS-56 export users: Australia (SQS-56), Greece (4 DE 1160s), Italy (4 DE 1160s, 1 DE 1160LF), Morocco (1 DE 1160), Saudi Arabia (7 SQS-56s), Spain (6 DE 1160s, 5 DE 1160LFs [for *Baleares* class], and 4 SQS-56SPs), and Taiwan (6 SQS-56s).

DE 1164 users: Greece (4 VDSs for MEKO 200s), Italy (10 delivered, 2 DE 1164LFs on order for *Animoso* class).

◆ Raytheon DE 1167 (SQS-58)

Raytheon's hull and variable-depth sonar for smaller ships (hull, fish, or combined) operates in a 2-kHz band around 12 kHz, and there is also an 18-kHz version. The passive-search band is 2

kHz wide, centered on 4.5 kHz. Reception is on 36 preformed beams, with a selectable 10×13 deg sum beam for listening. Comparison of half-beams allows a tracking accuracy of 2 deg. Range resolution is 8–64 yd. The active display operates on 256 range cells and 180 bearing cells (2 deg each), with 2 intensity levels. Pulses are FM slides covering 1 kHz (6.25, 50, 100, 200 msec). Source levels are 225 dB (triple beam) and 215 dB (ODT). The ODT mode is limited to 5-kyd range, to maximize data rate on the most urgent threats. The more concentrated triple beam is necessary to provide enough energy for greater ranges. The display can show a 3- or 6-ping history. Range scales are 2, 4, 8, and 16 kyd.

In search operation, the sonar interlaces tribeam and ODT ping modes, the tribeam mode consisting of 12 transmissions in sequence to cover the full 360 deg. In this mode the sonar usually transmits 200-msec pulses, although it can use 50-msec pulses. In the evaluation mode, the sonar transmits ODT pulses, with lengths of 6.25, 50, and 200 msec. There is a listening (passive) mode and an optional passive mode, which can operate simultaneously with the active mode (at lower frequency).

The display is a CRT that can be used in various formats: a B-scan (with over 300 lines of sonar data) for active search, a restricted B-scan for sector scanning (showing target doppler), a passive waterfall (which shows both short- and long-term averaged data), and a variety of alphanumeric.

The VDS weighs 10,260 kg (6.4 m³). The hull sonar weighs 4375 kg (12 kHz) or 3920 kg (18 kHz). Only 1 operator is required. MTBF: 1 hr of service is required for 60 days of operation. MTTR is 30 min. The sonar uses built-in test equipment.

Another version, DE 1167LF, operates at 7.5 kHz (and can support a 7.5- or 12-kHz VDS). The 7.5-kHz hull array is 48 in in diameter, compared to 28.2 in for the 12-kHz array. The 7.5-kHz VDS fish weighs 50,300 lb; the 12-kHz fish, 23,550 lb. As of 1985, 2 DE 1167LF/VDS had been sold to Egypt, to equip *Descubierta*-class frigates. As of 1986, a total of 25 DE 1167 had been sold. Some parts are made in Italy by Elsag.

SQS-58(XN-1), on Raytheon's test ship *Sub Sig-II*, is a DE 1167. The U.S. Navy uses the DE 1167 engineering model to track nuclear submarines on their sea trials; Raytheon claims that the model has operated for more than 8000 hr and that it has "perhaps more 'ping time' against live submarines than any other surface ship system anywhere." Raytheon currently refers to the hull version of this sonar as DE 1167HM. It incorporates the operating techniques and processing power of the larger DE 1160/1164 series but can be installed on board ships displacing as little as 200 tons.

Users: Egypt (2 DE 1167LF/VDS), Italy (9 DE 1167LFs and 4 DE 1167 for corvettes), Japan (4 DE 1167LFs, presumably for the MSA), and Korea (26 DE 1167s).

◆ Raytheon DE 1191

Raytheon's hull sonar combines features of the DE 1190 transmitter, the DE 1160 receiver and display, and a new LF transducer. The solid-state transmitter (DE 1190 SST) is sold as an SQS-23 upgrade. DE 1191 includes a 48-kW transmitter (14-dB improvement over SQS-23) and eliminates 40 cabinets and boxes of vacuum tubes and 10 motor generators, saving 450 ft³. DE 1191 requires 5 cabinets. It uses the same dome and transducer as SQS-23, so no drydock work is required for installation. Typically the SST is installed first, then the more expensive receiver/display. Features include memory-refreshed B-scan and multiping storage.

DE 1190 is offered in 12-, 24-, 36-, 48-, 72-, and 96-kW versions, using 1-kW transmitter modules. Peak power is 28–56 kW. DE 1191 peak power is 120 kW (average 10 kW).

The DE 1191 transmitter costs \$1 million. By November 1989 Raytheon had sold 80 transmitters. Known buyers were Australia (3 for DDGs), Germany (3 for DDGs, later replaced by DSQS-21s), Greece (3, plus an option on 3, for FRAMs), Pakistan (6 for FRAMs), Korea (8 for FRAMs), Taiwan (12 for FRAMs), and the United States (48 for ships with SQS-23 sonars, including the DDG 37, CG 16, CGN 9, and CGN 25 classes).

◆ TAVA

Gould's Towed Active Vertical Array is for a joint NATO SACLANT/NAVSEA/NUSC program. TAVA was tested in the Mediterranean in October–November 1986. The transmit array was 16 Sanders Model 30 flexensional transducers in 2 vertical struts, providing left/right cardioid patterns. The beam could also be steered vertically. Signal strength was 226 dB at 1125 Hz. The receiver was towed separately, using a critical-angle tow. The first 2 weeks of the sea trial were spent on acoustic and hydrodynamic tests; the third was spent operating with a *Glavkos*-class (Type 209) submarine, and the fourth week was spent acquiring environmental data.

This program was established in January 1986.

The transducer "fish" of the Gould TAVA (towed active vertical array), showing the vertical column of 16 flexensional transducers in 2 vertical struts (for left/right patterns; the beam could also be steered vertically). When not in use, the column could swing back into its recess to reduce drag. (Gould)

◆ WQRSS

Whitehall's Quick-Reaction Surveillance System is a containerized towed array proposed by Whitehall Corp. about 1985. The navy leased 3 units under its FY86 program, operating them very successfully; this system was, in effect, SURTASS without the command/control aspects. Whitehall manufactures the "wet end" of the SURTASS sonar (UQQ-2) and has made numerous hydrophone arrays for oil exploration.

◆ POS Ship (ASW Ship) Upgrades

Secretary of the Navy Garrett listed recommended upgrades to existing U.S. ASW surface combatants (protection of shipping [POS] ships), the *Spruance*-class destroyers, and the *Perry*- and *Knox*-class frigates on 16 August 1989. Given insufficient funds, he expected that the *Spruances* and *Perrys* would be upgraded, but that the *Knox* class will be relegated to reserve without modernization. The lists are presented here as indications of the sort of systems the U.S. Navy is likely to buy as it modernizes existing ships. Although not all of the items are ASW-related, many of them are. In the case of the *Knox* class, although it is unlikely that the U.S. Navy will carry out the list, the projected program suggests what likely foreign buyers may need. First priority went to the dual-role (battle group and POS) *Spruances*, and second to the *Perry*-class, the main POS force with the longest remaining service life.

Spruance Class

(a) Programmed

—Tactical towed array, acoustic processor, and ASW helicopter data link (SQQ-89(V)1 system with SQS-53C sonar and SQR-19 array; trials ship was DD 980, 1985). DD 966 had an SQR-15 surveillance array during a Western Pacific cruise in 1985. The Mk 116 Mod 5 underwater FCS is to be fitted, as well as a new underwater telephone, WQC-5.

—LAMPS Mk III with dual RAST on all ships.

—Mk 41 vertical launcher on 24 of 31 ships (Tomahawk in 2 quad armored box launchers on the others). The 61-cell vertical launcher replaces the ASROC forward; without a vertically launched ASROC or Sea Lance, these ships lose their all-weather standoff capability. They will ultimately carry up to 45 Tomahawks plus 16 vertically launched ASW weapons. The box-launcher ships, which retain standard ASROC, are DD 974, 976, 979, 983, 984, 985, 989. DD 963 and 990 were the first vertical-launcher ships. The Mk 41 system can also accommodate Sparrow or Standard (AAW) Missiles.

—CIWS Block I upgrade.

—Mk 50 torpedo handling and stowage.

—Radio D/F to support OTH-T.

—ECM upgrades (SLQ-32(V)2 replaced by (V)3).

—TAS (and other acquisition systems) for ASMD (TAS Mk 23 was on board half the class as of 1985). This program also envisages replacement of the current SPS-40 by SPS-49.

—Survivability and stability improvements.

(b) Recommended Additions

—Improved towed array with LF active transmission and reception and full-spectrum processing.

—Improved antimissile hard-kill systems (RAM).

—Added missile fire-control channel (perhaps in connection with missiles carried in vertical launchers forward).

—Integration of hard and soft kill for missile defense (RAIDS, see the anti-aircraft section).

—Survivability upgrades.

Perry Class

—Improved towed array with active transmit/receive subsystem (i.e., active adjunct) and full-spectrum processing.

—SYS-2(V).

—Mk 92 Mod 6 (CORT).

—RAM missiles (to be fired from the Mk 13 launchers).

—ECM upgrades: RAIDS and Sidekick.

—Survivability improvements.

Knox Class

(a) Completion of Existing Upgrade Programs

—Towed array for 43 of the 46 ships.

—Digital hull sonar (SQS-53 vice -26).

—Torpedo countermeasures.

—Silencing.

—ESM upgrades.

—Radar upgrades.

—LAMPS tacnav system (to accommodate modernized LAMPS I).

—Baseline CIWS.

—Baseline Harpoon.

(b) Warfighting Improvements

—ASW detection and target-classification improvements.

—Full spectrum acoustic processors, multimode acoustic array (i.e., active adjunct to towed array).

—FFISTS and JOTS (see the Surveillance and Control section).

—Tactical plotting system (NC-2) replacement.

—Digital upgrade to underwater FCS.

—State-of-the-art tactical-decision displays.

—ECM upgrades.

—Detection-to-engagement improvements (i.e., a more automated combat system for faster reaction).

—CIWS Block I.

The principal warfighting improvement is FFISTS, in effect a small-ship ASW-oriented automated combat information system (it does not include an automated interface to weapons). The FY83 program included installation of an ASW Tactical Data System (TDS) on board all the *Knox*-class frigates, but that was not done, and there were several proposals. FFISTS was (or is being) installed on board 11 ships. Now many of the ships are probably to be transferred in the near future, and their buyers may well find similar modernization attractive, particularly since CDSs are becoming so much less expensive.

UNDERWATER FIRE-CONTROL SYSTEMS

◆ Mk 101

The first U.S. post-World War II submarine FCS survives in small numbers (see the list of versions, below). It is worth describing in detail because it is typical of the technology developed during the first postwar decade, examples of which survive alongside the much later electronic systems. The limitations inherent in the mechanical Mk 101 explain the importance of the transition to digital computers. The basic architecture of Mk 101 carries over into the later systems through Mk 113. Contracts for Mk 101 and the parallel surface Mk 102 were let in 1948, and Mk 101 entered service in 1952. Mk 101 used the new Mk 55 computer-analyzer (also in contemporary surface-ship ASW systems) and an automatic plotter (which replaced the older DRT). Mk 101 was part of a modular program. It was built around Analyzer Mk 7 Mod 0. Mods 1 and 2 were used in the much simpler Mk 106 system (described below). Similarly, Mk 101 used Position Keeper Mk 1 Mod 0; the now-extinct surface system, Mk 102, used Mk 1 Mod 1.

As in other contemporary underwater FCSs, Mk 101 consisted of an analyzer (Mk 7), a position keeper (Mk 1), and an angle solver (Mk 11). The position keeper projected ahead (generated) target position (bearing and range) and motion (course and speed) on the basis of the course and speed estimated (from sonar, radar, and periscope observations) by the analyzer. It constantly fed these data back to the analyzer for comparison with actual observation, and thus for correction. The same data were also fed to the angle solver, which used them to calculate appropriate torpedo gyro and speed settings, based on known torpedo ballistics and also on the desired torpedo spread. These torpedo settings were fed to the torpedoes via a relay transmitter and amplifiers. Because the torpedo ballistics were present in the angle solver in analog form, that instrument had to be modified physically to handle any torpedo very different from those originally planned.

Analyzer Mk 7 estimated (solved for) target course and speed, assuming that the target followed a straight course. It could work from 3 discrete target bearings and 1 input of either target range or speed, or (if both own-ship and target were moving) target course. The accuracy of the solution depended on the time intervals between bearings and on the bearings themselves. Total analysis time was limited to 20 min. The operator could discard the second or third bearing while the analyzer ran, inserting a preferred observation later on (the starting point could be changed by pushing a reset button). Range, target course (target angle), or target speed were entered by hand crank; all 3 functions varied when the hand crank was turned. A generated (calculated) range from the position keeper could be input automatically. When a range, course, or speed was inserted, the computer obtained the unique solution, taking own-ship motion into account. This solution differed from most types of bearings-only solutions obtained by earlier systems in that own-ship maneuvers were not restricted to fixed course and speed during the analysis period.

Alternatively, the analyzer could work from a pair of end points (target bearing and range), a method called end-point analysis.

The position keeper projected ahead target motion on the basis of the analyzer solution. This projection could be used as a check on target motion. For example, a target turn could be detected when observed target bearings began to deviate from those estimated. The position-keeper displayed target course and speed; target angle; target relative course; ratio of target relative course to range; range; own-ship course; bearing of 1st, 2nd, 3rd observations introduced into the 3-bearing method; analysis time from first observation; time interval between 1st and 2nd observations in the 3-bearing method; and number of bearings inserted (not counting number dropped).

Unlike the analyzer, the position keeper could project ahead on the assumption that the target was turning: turning radius and turning rate were inserted by a knob. On this basis it could

calculate target track curvature (change in target course per unit travel) as well as bearing, range, target speed, and target angle. Normally the analyzer fed the position keeper automatically, but in the event that the computer failed the position keeper could be fed manually, based on the last known values for corrections (which were displayed on the dials until the operator used them).

Unlike the earlier underwater FCS computer (Torpedo Data Computer Mk 4), Mk 101 solved for only 1 torpedo nest at a time. That was practical because the angle solver reached a solution much more quickly (and without swinging around the final solution, as in earlier systems), and because it could very rapidly set the electrically set torpedoes. The angle solver had a switch to select torpedo tactical data to suit the particular Mk and Mod of torpedo to be fired; this switch allowed for up to 7 sets of torpedo data. The firing panel could allow for either angular or linear spreads. A stratum depth-warning system lit a warning indicator when own-ship maneuvered into the depth operating range of her homing torpedoes.

Some key torpedo parameters were still set manually, in the torpedo room: torpedo enabling run and running depth.

The chief improvements over earlier underwater FCSs were automatic reception of all target data, automatic transmission between units, nearly instantaneous synchronization to incoming data, automatic analysis of target course and speed, longer position-keeping range (34,000 yd), addition of a frozen display of bearing and range corrections and time for accurate mental analysis, nearly instantaneous angle-solver solution, longer angle-solver torpedo run (20,000 yd or 15 min), rapid changing of torpedo tactical data inputs in the angle solver for various types of torpedoes, and addition of curved-course solutions.

Both the quicker solution and the provision for curved target course were essential in a system intended to deal with the new generation of very fast and very maneuverable submarines. Target curvature was transmitted automatically to the angle solver.

The original Mk 101 could handle straight-running torpedoes Mk 14 and Mk 18 (electric) as well as Mk 27 Mod 4, Mk 28, Mk 35 Mods 2 and 3, and Mk 37 homing torpedoes. It was modified for 3 major new torpedo generations: wire-guided homing weapons (particularly Mk 37), the nuclear Mk 45, and the much faster Mk 48.

Wire guidance required a new device, Torpedo Director Mk 37. It was used to fire the abortive Mk 39 Mod 1 torpedo in a bearing-rider mode (rather than in a predicted-fire mode, as in earlier fire-and-forget systems). The operator manually steered the torpedo to keep it on the bearing line between submarine and target. The wire carried indicated torpedo speed back to the submarine, and a computer used this speed and the series of guidance commands sent out to the torpedo to dead-reckon torpedo position in the water (there was, and for that matter almost certainly is, no feedback to compensate for factors such as currents between the submarine and the target). The same computer converted relative target bearing (e.g., as determined by a passive sonar) into true target bearing for comparison with true torpedo position and bearing. Concentric dials on the face of the director showed true torpedo bearing and true target bearing, and the operator turned a STEER knob on the director to match them. The commands went simultaneously to the torpedo and to the director (for further dead-reckoning). The torpedo's own passive homing system took over when it began to hear signals from the targeted submarine.

Bearing-riding was relatively simple to implement, but it imposed severe limitations. First, the torpedo necessarily followed an energy-inefficient pure-pursuit course; there was no attempt at a torpedo equivalent of proportional navigation. That limited the effectiveness of a slow torpedo such as Mk 39. Second, since the torpedo always lay on a line between submarine and target, it always produced a noise strobe pointing back toward the launching submarine. That was not a very serious issue for a very quiet torpedo such as Mk 39 or its successor, Mk 37, but it could become important for a fast noisy one. Wire guidance could in theory allow for dog-leg courses, but such tactics re-

quired a much more elaborate plot or computer, permitting the operator to visualize the tactical situation. Dog-legging and proportional navigation could also help overcome whatever countermeasures, such as bubble screens and decoys, a submarine might leave in her wake since in these cases the torpedo might well approach from other than a stern aspect.

The Mk 37 torpedo, the wire-guided version of which entered service in the early 1960s, was designed for more varied trajectories, and it used a more sophisticated director, either a later version of Mk 37 or the new angle solver Mk 18 Mod 0 (which was developed specifically to control the new nuclear Mk 45 torpedo, ASTOR, which entered service at that time). Mk 18 was developed (by Sperry) as part of the program for ASTOR (Mk 45), the fast nuclear torpedo, but it replaced both the earlier angle solver (Mk 11) and torpedo director Mk 37 in FCS Mk 101. In the simpler Mk 106 (described below), Mk 18 Mod 1 and a transition section replaced the angle solver in the system's torpedo data computer Mk 4 (which was then reduced to functioning only as a position-keeper). Mk 18 differed from earlier angle solvers mainly in its ability to provide steering information for wire-guided torpedoes. Unlike Mk 37, it could guide a torpedo either in bearing-rider mode or in corrected-intercept mode. The latter was not a pure dog-leg, but it placed the torpedo ahead of the target in a position to be steered into it. As in Mk 37, the operator steered the torpedo directly and so could control only 1 torpedo at a time. Because it was used to control a nuclear torpedo, Mk 18 also provided a special display (a counter showing error in run-to-burst) and dial to correct the enabling run set when the torpedo was launched.

Mk 18 could change torpedo course in 2-deg increments, and enabling run in 100-yd increments. Limitations: torpedo speed 15–60 kt, torpedo run 300–35,000 yd, target speed 0–40 kt, own-ship speed 0–40 kt, target range 0–35,000 yd, torpedo depth 0–1400 ft. Like its predecessors, Mk 18 was still an analog computer with special components for particular sets of torpedo ballistics, in this case for torpedoes Mk 14 Mods 3A and 5, Mk 16 Mods 6 and 7, Mk 27 Mod 4, Mk 28 Mods 2 and 3, Mk 37 Mods 0 and 1 (the last with the angle solver modified), Mk 39 Mod 1, Mk 45 Mod 0, and standoff mines Mk 27 Mods 0–3.

By the early 1960s submarines were fitted with angle solver Mk 18 Mod 2, which could handle the later version of the Mk 45 nuclear torpedo. Modernization to handle the Mk 48 torpedo required another change, to angle solver Mk 18 Mod 4.

By this time, too, submarines were commonly using TMA, which was far beyond the capabilities designed into analyzer Mk 7. Hand-plotting techniques seemed less and less attractive as sonars improved and as weapons ranges increased to and beyond 10,000 yd. Several automatic or semiautomatic plotters were developed about 1959, of which Mk 19 survived in this and later submarine FCS installations. Plotter Mk 19 is a DRT modified to perform 1 of several TMA plots called the strip plot. The strip plot is a true navigational plot showing a series of bearings (typically 1/min) from own-ship. If the target submarine is running in a straight line, its course is represented by a straight line on the true navigational plot. A plastic strip for assumed target speed, calibrated in yd/min, is placed across the bearing lines until a best fit is obtained between minute markings on the strip and minute bearing lines. The line drawn along the edge of the speed strip is the target's track; its direction is the target's course; and the distance from its intersection with the last bearing line is the range. Use of the wrong speed strip will yield a fairly accurate course but an inaccurate range (in error by the same percentage as the speed). If the target zig-zags, the wrong speed strip will yield a discontinuous estimated course, and that will eventually show that the wrong speed strip is being used.

Mk 19 receives continuous own-ship course and sonar bearing data, displaying true target bearing as the direction of 2 small arrowheads optically projected onto a sheet of white paper on the plotting surface. Midway between the arrowheads is an optically projected light spot representing own-ship's present position. At 30-sec intervals an internal timer clicks audibly to alert

the operator. The operator then lays a straight edge along the 2 arrowheads and draws a line in the direction of true target bearings. After having drawn 3 or more lines, the operator uses plastic speed strips to determine the target's course. At the ranges and speeds common in the late 1950s, the operator could generally obtain a solution in 5 min. The plot is a record of own-ship's past and present position, target's present course and position, target's range, target's angle on the bow, and CPA.

Mk 19 is still in use, despite the advent of more automated means of TMA, because it gives a manual check on a computer solution that can go badly awry.

Where noted below, modification to fire Mk 48 torpedoes generally involved addition of tone generator Mk 47 Mod 0, control console Mk 66 Mod 1, weapons simulator Mk 22 Mod 0, and plotter Mk 19 Mod 0 or 1 as well as a new angle solver (Mk 18 Mod 4).

Versions (dates, where given, are dates on which nomenclature was assigned or system makeup officially changed; they are not necessarily dates on which physical changes were made):

Mod 1 Installed in the attack teacher Mk 7 at New London.

Mod 2 Installed on board the *Grampus* (SS 523). Modified 1963: position keeper Mk 1 Mod 0 changed to Mod 2; angle solver Mk 11 Mod 0 replaced by Mod 2; torpedo director Mk 37 Mod 1 added. At this time approximate weight was 10,400 lb. This version was similar to Mod 3 but lacked the Type 6 periscope input (via stadimeter) and had to control more tubes. In this ship Mod 2 was replaced by Mod 13. The *Grampus* was the only U.S. World War II-built submarine fitted with the Mk 101 system.

Mod 3 Original FCS of the *Tang* class (SS 563–66, 568); replaced by Mods 13 and 14 and then by Mod 18. This was the main version of the system. Unlike the other versions, Mod 3 required a range converter Mk 3 Mod 0 because the submarine was equipped with a Type 6 periscope (which incorporated a stadimeter and, thus, converted subtended angle automatically to range, given a manual input of target masthead height).

Mod 4 FCS of the SSK 1 (*Barracuda*) -class ASW submarines. Compared to Mod 3, Mod 4 lacked the stadimeter input and controlled fewer tubes. Modified in 1963 analogously to Mod 2. Approximate weight was 5400 lb.

Mod 5 Not assigned.

Mod 6 FCS of the first 2 nuclear submarines, *Nautilus* and *Seawolf*. They were modified to fire Mk 45 torpedoes and then, in December 1965, to fire Mk 48.

Mod 8 This version was modified for Mk 45 and then for Mk 48 torpedoes (December 1965). *Seawolf* (SSN 575) FCS.

Mod 10/16/20 Mod 10 was the original fire control of the *Barbel* class, incorporating torpedo director Mk 37 Mod 0. Modified to control Mk 45 torpedoes (torpedo director and angle solver Mk 11 Mod 4 replaced by angle solver Mk 18 Mod 2), it became Mod 16. This version incorporated plotter Mk 19 Mod 0. Approximate weight was 5500 lb. Modified to control Mk 48 torpedoes, it became Mod 20 (December 1965). Mod 20 is currently installed on board the *Bluefish* (*Barbel* class), which will probably be transferred abroad.

Mod 11 This was the FCS for the large nuclear submarine *Triton*. It was originally fitted to fire Mk 45, and it was ordered modernized to fire Mk 48 in December 1965 (but the ship had long been decommissioned, and she was not modified).

Mod 12 This version was originally fitted to fire Mk 45 and then was modified in December 1965 to control Mk 48 torpedoes.

Mod 13 This version, introduced in 1957, superseded Mods 2 and 3. About 1960 it was fitted to fire Mk 45 torpedoes. Angle solver Mk 18 Mod 0 was replaced by Mod 2 (October 1963). Total weight was about 5200 lb.

Mod 14/18 This was a Mod 3 modified to control wire-guided torpedoes (1959). About 1963 the Mk 18 Mod 2 angle solver was fitted, to control Mk 45 torpedoes (in the *Trigger* the new angle solver replaced a Mk 37 Mod 0 torpedo director, and in the *Gudgeon* it replaced a Mk 18 Mod 0 angle solver). Approximate weight was 6500 lb. This was probably the system initially installed on board the *Gudgeon*. Modified to fire Mk 48 torpedoes (December 1965), it became Mod 18, which survives on board *Tang*-class submarines in Turkish service.

Mod 15/19 Modified October 1963 to control Mk 45 torpedoes, using angle solver Mk 18 Mod 2 instead of Mk 11 Mod 4 and torpedo director Mk 37 Mod 0. One plotter Mk 19 Mod 0 was added. Approximate weight was 6500 lb. Modified to fire Mk 48 torpedoes (December 1965), it became Mod 19, the final *Skate*-class FCS.

Mod 17 *Skipjack* class: Mod 13 modified (December 1965) to control Mk 48 torpedoes.

◆ Mk 105

Mk 105 was a simpler alternative to the Mk 102 fitted to early postwar antisubmarine destroyers, such as the DDEs. It was first tested in 1952, using a QHB scanning sonar. Surviving examples use SQS-4 or its variants. It controlled Hedgehogs, both fixed and trainable, the Weapon Alfa rocket projector, torpedo tube Mk 25 (for non-wire-guided torpedoes), and depth charge racks and throwers. Mk 105 survives on board ships fitted with Hedgehog projectors. In some ships, such as early FRAM I destroyers, it was installed alongside the later Mk 111. In FRAM II destroyers, it is the sole ASW FCS, combined with a special panel (Mk 264) that enables it to fire lightweight torpedoes from Mk 32 tubes.

Mk 105 is built around Librascope's attack director Mk 5, its electromechanical computer. Mk 5 replaced the earlier attack plotter Mk 1 as a basic attack aid. It generates target position data for position keeping (target-motion prediction) and for aided sonar tracking (which allows the sonar operator to detect target turns). The series of target positions provided by the ship's active sonar is automatically analyzed to yield target's course and speed, and incremental values of target bearing and range are transmitted to the sonar for aid-tracking. They are also used internally to project ahead target position (position keeping). If sonar contact is lost or interrupted during tracking, and the sonar tracking mark switches opened, the attack director automatically changes its mode of operation to position keeping and continues to generate the present position of the target and to predict the future position of the target based on the last known course, speed, and position of the target. The attack director thus serves as a position keeper for the ASW system so that attacks can be conducted with intermittent sonar contact or even after contact has been lost. Inputs are received as synchro signals or are entered manually: relative sonar bearing, sonar range, own course, own speed, and sonar range correction (from the range recorder). Constants and spot corrections are entered through hand cranks.

Mk 105 was designed from the beginning to control both trainable and fixed weapons (fixed Hedgehogs and depth charges). It, therefore, generates solutions for both types of attack simultaneously and accepts attack constants for both types of attack. Manual inputs are (i) attack data: target depth and target turn; (ii) constants for fixed attack, parallax plus effective range, dead time plus time of flight, sinking rate; (iii) constants for trainable attacks, parallax, dead time plus time of flight, sinking rate.

Not only does the attack director generate a continuous solution for the stern-dropped DC attack but it also indicates at each instant how far to the right or left of the target advance position the charges will be dropped if own-ship continues on the present course. The depth-charge attack dial shows the lateral attack error in yards.

The attack director solves as readily for a curved-course as for a straight-course attack. If the target is observed going into a

turn during an attack, a target's course spot correction can be entered manually. When such a value is entered, the instrument corrects the input values of target's angle and speed to the ballistics section of the attack director to compensate for the effect of turn on the ballistic outputs.

Mod 0 tracked targets out to 3000 yd (the maximum effective range of World War II-type sonars such as QHB and QCU-2).

Mod 1 added hand cranks for manual inputs for testing (relative sonar bearing, sonar range, own-ship course, and own-ship speed). Target's maximum speed was changed from 20 to 25 kt.

Mod 2 was Mod 1 modified to provide for transmission of relative sonar bearing and horizontal sonar range. It was developed to permit synchro transmission of generated range and bearing to ballistics computers and to provide for increased range. Maximum sonar range was increased from 3000 to 6000 yd. Own-ship's maximum speed was 30 kt, and target's maximum depth was 1200 ft.

Mod 3 was compatible with the new SQS-4 sonar; it could transmit target's course from attack director to sonar repeater scope. That made for the most effective use of target aspect as seen on the repeater scope since aspect could be compared directly with the course of the target as determined by the attack director. That in turn was expected to make for greater accuracy and speed of target-course analysis and early-turn detection.

The associated Mk 1 A/S attack plotter (ASAP) shows the attack situation on a CRT. It is fed by the ship's dead-reckoning analyzer, sonar, and gyrocompass; the CRT shows own-ship's course, the path of each sound beam, and the position of the underwater target when contact is made. Because the target blip persists, the CRT shows a series of such blips in succession, and the target course can be estimated by drawing a line through them. The CRT also shows firing range and forward bearing for a Hedgehog, so that the correct train and firing time can be estimated.

The World War II destroyer escorts not fitted with Mk 105 had only the ASW attack plotters (Mk 1 Mod 2). Presumably, that applies to the 4 ships in the Greek navy and to 1 in the Uruguayan navy, which have never benefited from ASW modernization. Ecuador and Mexico both operate high-speed transports converted from destroyer escorts, probably equipped with ASW attack plotters. The other surviving destroyer escorts have all been modernized: 2 in the Philippines, 1 (and 2 very similar frigates) in Thailand, plus 1 in the Taiwanese navy (and 9 former high-speed transports converted to frigates). They, the PC-class corvettes, the PF 103-class frigates built for export, and the *Auk*-class corvettes in the Taiwanese and Thai navies, are all probably equipped with versions of Mk 105.

Versions (many extinct):

Mod 1 Destroyer-escort (DE 696, 697, 700) version with trainable Hedgehog (Mk 15) and 19-charge depth-charge pattern. It used attack director Mk 5 Mod 0, stabilization computer Mk 59 Mod 2, and attack plotter Mk 1 Mod 6.

Mod 2 Destroyer-escort version (DE 699 was prototype) for 2 fixed Hedgehogs (Mk 10) and a 19-charge pattern. The computer was Mk 23 Mod 4. This was the version on board modernized destroyer escorts.

Mod 3 Destroyer-escort version (DE 532) with 4 fixed Hedgehogs (Mk 11) and a 19-charge pattern (1951). The computer was Mk 59 Mod 2.

Mod 4 Destroyer-escort version (DE 152, 535, 644) with 2 trainable Hedgehogs Mk 15 and a 19-charge pattern, 1951. The computer was Mk 59 Mod 2.

Mod 5 For *Forrest Sherman*-class destroyers, to control 4 heavy torpedo tubes, 2 Hedgehogs Mk 11, and an 11-charge pattern (1953), using attack director Mk 5 Mod 2, computer Mk 59 Mod 7, angle solver Mk 17, and torpedo-course indicator Mk 3 Mod 1. There was no attack plotter, but this version did include plotter Mk 12 Mod 2. Mk 12 was used to smooth submarine-target depth data. An electronic stylus burned a small hole in

the paper to indicate a depth measurement, and the operator placed a horizontal cursor across the estimated average of a series of such holes. A second cursor could be used to estimate depth rate of change. In each case, cursor position and angle were automatically translated to the system computer.

Mod 6 For *Dealey*-class escorts, to control Weapon A (Mk 108) as well as depth charges, using attack director Mk 5 Mod 2 and computers Mk 59 Mod 8 and Mk 68 Mod 0 (for Weapon A). There was no attack plotter, but this system did include plotter Mk 12 (1954). This version was later converted to Mod 33, 37, and 38 (see below).

Mod 7 For DER 142, 244, 318, 333, 316, and 317, to control trainable Hedgehog (Mk 15) and depth charges, using attack director Mk 5 Mod 0 or 1 and computer Mk 59 Mod 8. There was no attack plotter (1954).

Mod 8 For converted *Gearing*-class DDEs, to control Mk 15 trainable Hedgehogs and depth charges, using attack director Mk 5 Mod 3 and computer Mk 59 Mod 8. There was no attack plotter (1954).

Mod 9 For DERs 133, 386, 393, 397, 539, 540, to control trainable Hedgehog (Mk 15) and depth charges, using attack director Mk 5 Mod 2 and computer Mk 59 Mod 8. There was no attack plotter (1954).

Mod 10 For *Sumner*- and *Gearing*-class destroyers and *Smith*-class minelayers (1955), using attack director Mk 5 Mod 3 and computer Mk 59 Mod 6. There was no attack plotter. Mod 10 was also installed on board some modernized *Fletchers*.

Mod 11 Shore-training version (1955), using attack director Mk 5 Mod 1, for the U.S. Naval Academy; there was no stabilization computer, but there was an attack plotter Mk 1 Mod 5 or 6.

Modes 12–13 Shore-training versions (1955), using attack director Mk 5 Mod 3; there was no stabilization computer or attack plotter.

Mod 14 For DDRs 711 and 742 classes (1955), replacing Mod 10; it controlled depth charges and 2 Hedgehogs Mk 10 or 11. The attack director was Mk 5 Mod 3, and there was no stabilization computer or attack plotter.

Mod 15/16 For *Forrest Sherman*-class destroyers (DD 945-series) with SQS-4 sonar; converted to Mod 16 when SQS-23 was installed (1955).

Mod 17 Maintenance-training version (1965).

Mod 18 For ASW destroyers *Carpenter* and *Owens*, equipped with 1 Weapon Alfa; it is a converted Mk 100. This system was removed in 1965 when the ships underwent FRAM conversion.

Mod 19 For ASW destroyers *Epperson* and *Basilone*, equipped with 2 Weapon Alfa; it is a converted Mk 100. This system was removed in 1965 when the ships underwent FRAM conversion.

Mod 20 For later and modernized *Forrest Sherman*-class destroyers, controlling 2 Hedgehog Mk 10 or 11 and 1 stern depth-charge rack; it was used on board ships where the requirement for electrically set torpedoes had been deleted. The system included attack director Mk 5 Mod 3 and computer Mk 59 Mod 7. There was no plotter (1960).

Mod 21 For FRAM II conversions of *Sumner*-class destroyers, using attack director Mk 5 Mod 5, computer Mk 59 Mod 10, and angle solver Mk 17 Mod 2, with torpedo-control panel Mk 264 Mod 1 (with 2 torpedo-course indicators Mk 3 Mod 1) to control 2 Hedgehog Mk 11, 2 torpedo tubes Mk 25, and 2 torpedo tubes Mk 32. Total weight was about 6000 lb (1964). See also Mod 34 below.

Mod 22 For FRAM II conversions of *Sumner*-class destroyers, equipped to fire Mk 37 Mod 1 wire-guided torpedoes; this version was tested on board *Robert K. Huntington* (DD 781) in 1960. It controlled 2 Hedgehogs Mk 11, 1 stern depth-charge

track; 2 torpedo tubes Mk 25 (for Mk 35 Mod 3, Mk 37 Mods 0 and 1 torpedoes), 2 Mk 32 tubes (for Mk 43, 44, and 46 torpedoes), and a DASH torpedo-dropping drone helicopter. The major components were attack director Mk 5 Mod 5, torpedo director Mk 37 Mod 1, angle solver Mk 17 Mod 0, computer Mk 59 Mod 10 or Mk 108 Mod 0, torpedo-course indicator Mk 3 Mod 1, a geographic display plotter (in effect, a PPI), and coordinate converter. Total weight was about 3714 lb (1960). See also Mod 34 below.

Mod 23 For FRAM II destroyers (DD 764 class), to control 1 trainable Hedgehog Mk 15, 2 torpedo tubes Mk 25, and 2 lightweight tubes Mk 32. The major components were an attack director Mk 5 Mod 5, a torpedo director Mk 37 Mod 2, angle solver Mk 17 Mod 2, computer Mk 108 Mod 0, computer Mk 110 Mod 0, coordinate converter Mk 54, and plotter NC-2 (1964). See also Mod 35 below.

Mod 24 Combination Terne/Hedgehog system, tested in DE 1035 and 1036 (1964).

Mod 27 For FRAM II destroyers (DD 805 class), controlling 2 Hedgehogs Mk 11, 2 torpedo tubes Mk 25, and 2 torpedo tubes Mk 32. Major components: attack director Mk 5 Mod 5, torpedo director Mk 37 Mod 2, angle solver Mk 17 Mod 2, computer Mk 108 or Mk 59 Mod 10, torpedo course indicator Mk 3 Mod 7, plotter NC-2, and coordinate converter Mk 54 (1964). See also Mod 37 below.

Mod 28 Maintenance trainer (1965).

Mod 30 For high-endurance coast guard cutters (*Hamilton* class), to control 2 fixed Hedgehogs (Mk 10 or 11) and Mk 32 torpedo tubes. The main components are attack director Mk 5 Mod 3 and control panel Mk 264 Mod 1; as these ships are modernized this system is superseded by Firing Panel Mk 309.

Mod 33 For modernized *Dealey*-class ships, replacing Mod 6, for use with SQS-23 sonar and Mk 32 torpedo tubes. Major components are: attack director Mk 5 Mod 5, computer Mk 68 Mod 0, computer Mk 59 Mod 8, and control panel Mk 264 Mod 1. There is no plotter (1966).

Mod 34 Mod 21 and 22 (FRAM II destroyers) with Mk 37 torpedo capability deleted (1968); the system controls 2 Hedgehogs Mk 11 and 2 Mk 32 tubes. Major components: attack director Mk 5 Mod 5, computer Mk 59 Mod 10 or Mk 108 Mod 0, and control panel Mk 264 Mod 1.

Mod 35 Mod 23 with Mk 37 torpedo capability deleted (1968). Major components: attack director Mk 5 Mod 5, computer Mk 108, computer Mk 110, and control panel Mk 264 Mod 1.

Mod 36 Mod 27 with Mk 37 torpedo capability deleted (1968). Major components: attack director Mk 5 Mod 5, computer Mk 59 Mod 10 or Mk 108 Mod 0, control panel Mk 264 Mod 1.

Mod 37/38 Mod 6 without Weapon Alfa capability, for DEs 1014 and 1021: attack director Mk 5 Mod 3 or 5, computer Mk 59 Mod 8, and control panel Mk 264 Mod 1 (to control Mk 32 tubes). Approximate weight is 1534 lb (1970). Mod 38 is the equivalent for DEs 1015, 1022–30.

◆ Mk 106

This postwar FCS was for older submarines that could not accommodate the full Mk 101. The system was built around the earlier Torpedo-Data Computer (TDC) Mk 4. The TDC itself was introduced before World War II to provide continuous (synchronous) solutions for torpedo gyro angle (lead angle) in terms of target range and bearing so that torpedoes could be fired at any time. In the absence of a TDC, the torpedo gyro angle had to be calculated on a slide rule before firing, the submarine maneuvering to the proper position and bearing to await the target. TDC Mk 4 differed from Mk 3 in adding a receiver section, for target range and bearing from sonar and radar. In both cases, estimated target angle on the bow and estimated target speed were inputs. The receiver section of Mk 4 includes a

sonar-data converter (to correct for parallax due to target motion while the ping makes its round trip, or while passive sound travels from target to sonar, and also to allow for variable sound speed). Other possible inputs are periscope and radar data. Own-ship data are taken from the gyrocompass, the pit log, and the dead-reckoning analyzer.

These data flow into a position-keeper, which projects ahead relative target position (bearing, range, and target angle); the position-keeper also provides the initial estimate of target course. All of these estimates are based on intermittent observations. Given these data, the other main element of the TDC, the angle solver, generates torpedo gyro angles, estimated running times, and track angles (it provides solutions for both the forward and after tubes simultaneously). Own-ship and target dials show calculated gyro and track (target course relative to own-ship) angles. Mk 4 accepts torpedo speed settings of 18–55 kt and values of torpedo run differences from –100 to +150 yd; torpedo spreads can be up to 900 ft forward and aft of the estimated target mid-point position.

The major difference between Mk 106 and the earlier submarine FCS was that it could send gyro angle and enabling-run orders directly to electrically set torpedoes as 400-cycle synchro signals; it could also mechanically set older torpedoes. Mk 106 generates (calculates) target's position as a function of problem time; solves for the impact point of the target and torpedo; calculates torpedo's gyro angle; and sets synchronous gyro-angle functions into the torpedo, together with the synchronous depth and enabling-run functions and the nonsynchronous stratum function. These functions sufficed for free-running torpedoes, but the advent of homing weapons (particularly Mk 37) required more (see Mod 5, below).

The TDC itself is limited in that it maintains an estimate of target position but not of target course and speed (which are only indirectly estimated). In the more elaborate Mk 101, the position keeper was combined with a target analyzer. The target analyzer calculated target speed and course from bearing and range (and own-ship) inputs; target course was displayed in the form of a dial marked to represent the heading of the target (a similar dial showed own-ship heading). This information was fed back into the position-keeper part of the system to improve overall system accuracy. Some versions of Mk 106 had a separate analyzer (Mk 7), but it had no direct electrical connection back into the associated TDC; it acted instead as a manual check on the accuracy of the solution being developed by the TDC. See the description of FCS Mk 101 for analyzer Mk 7. Analyzer Mk 7 Mod 1 was specially designed for Mk 106. Mod 2 (for Mk 106 Mods 2, 3, 4, and 6) is identical to the Mod 0 of Mk 101 except that it operates on 60-cycle synchro inputs.

Mk 106 transmits gyro angle directly to electrically set torpedoes (TDC Mk 4 transmitted it to an indicator in the torpedo room, and it was set mechanically into the torpedo), also transmitting enabling run and ordered (running) depth. Presets for homing torpedoes are entered via a control panel. The system also incorporates a monitor to check whether these automatic settings are in fact transmitted correctly.

The original versions, Mods 2 through 9, differ mainly in the number and arrangement of torpedo tubes they control. Like Mk 101, Mk 106 was designed to track targets at ranges up to 30,000 yd, and it could provide initial gyro angles and enable ranges for torpedo travel up to 15,000 yd. In the later versions, maximum target depth was 1000 ft, and maximum target speed was 40 kt.

Mk 106 was designed to control both mechanically set (torpedoes Mk 14, 16, 18, 23, and 28 and mines [homing torpedoes] Mk 27) and electrically set (torpedoes Mk 14 Mod 5, Mk 16 Mod 5, Mk 18 Mod 4, Mk 27 Mod 4, Mk 28 Mod 2, Mk 35 Mods 2 and 3, and Mk 37 Mod 1, and mine Mk 27 Mod 4) weapons. Mk 37 Mod 1 was wire-guided. Later Mk 106 was modified to accept passive-range data from PUFFS (BQG-4) and to control newer wire-guided torpedoes (Mk 37 and the nuclear Mk 45, ASTOR). This capability was associated with torpedo director Mk 37 or with angle solver Mk 18.

The final versions controlled the Mk 48 torpedo. They were all equipped with Mk 66 torpedo-control consoles, which set the torpedoes and controlled them after launch, supplementing the existing FCSs. Mod 0 weighs about 750 lb; Mod 1 weighs about 365. Mod 1 at least suffices to monitor, display, control, and command-guide 2 Mk 48 Mod 0 torpedoes in their tubes and in the water. It is generally associated with a Mk 47 tone generator. Mods 0 and 1 are used with FCSs Mk 101, 106, 112, and 113; Mod 2 is used only with Mk 113 Mod 10 and later systems. It is designed to work with digital FCSs. The earlier wire-guided torpedoes, particularly Mk 37 Mod 1, used a relay transmitter and an amplifier to produce the necessary DC signals. Presumably, the use of a tone generator indicates that Mk 48 uses digital rather than analog steering signals. These versions all included plotter Mk 19 (see FCS Mk 101, above).

All of the original versions were built around TDC Mk 4 Mod 24, which incorporated synchro transmitters to both the torpedoes and the position-keeper section. Existing Mod 24s were ordered converted to Mod 28 in 1964, a change that well illustrates the very tight limits imposed by electromechanical computers. The angle solver in Mk 106 (and the similar 1 in Mk 101) were designed to deal with relatively fast torpedoes (the speed limits were 18 and 55 kt) and relatively short runs (479 sec, corresponding to 4790–14,600 yd for these speeds).

When the Mk 37 torpedo was adopted, the existing ballistic cams and plugs delivered for Mk 35 Mod 3 (seawater battery) were initially used, but the TDC had a torpedo-run limit of 7000 yd (Mk 37 actually ran as much as 23,000 yd at 17 kt [2435 sec] and 10,000 yd at 25 kt [720 sec]). The TDC had a minimum speed limit of 18 kt, corresponding to a maximum range of 4600 yd. The use of an improper speed made for a calculated run 6% short of the target-impact point. As a makeshift, operators used proportioned speed factors, solving a scaled problem on the TDC (increasing torpedo's speed, and, in proportion, increasing target's speed just before firing to maintain accurate position keeping for the greatest possible time). TDCs were modified about 1959 to allow for a run of about 8000 yd, but that was still hardly enough. Only in 1959 was a solution proposed: a switch (actually an electromechanical shifter on the target's speed shaft connecting the position keeper to the angle solver) that could convert the angle solver to lower-speed operation by scaling down target's and torpedo's speed inputs by a factor of 1.8 (the problem was geometrically similar). In this case the maximum allowable torpedo run was scaled by 1.8 to 862.38 sec, but target's maximum speed (40 kt in the unmodified TDC) was scaled down to 22.2 kt, and the torpedo's speed range was scaled down to 10–30.55 kt. The increased allowable running time allowed for ranges of 8253 yd at 17 kt and 12,137 yd rather than 6743 at 25 kt. This modification was clearly less than completely satisfactory, but its acceptance suggests just how difficult anything more complete would have been. Even this change took 3 days to install.

Versions:

Mod 1 Evaluation model.

Mod 2 For fleet submarines converted to radar pickets. The 6 forward tubes were modified to accept electrical setting commands from the FCS. Total weight was about 4900 lb.

Mod 3 Special version for *Grouper* (SSK 214), to test the wire-guided Mk 35 Mod 1 torpedo. It included analyzer Mk 7 Mod 1 and weighed about 6100 lb. Two forward and 4 aft tubes were modified for electrical setting.

Mod 4 Guppy IIA conversions. Some were later converted to Mod 14. Analyzer Mk 7 Mod 2 or 3. All tubes were modified for electrical setting.

Mod 5 Guppy I, Guppy II, and fleet snorkel submarines (austere modernization), without any analyzer; TDC Mk 4 Mod 26. Only 2 forward and 2 aft tubes were modified for electrical setting. Mod 5 became obsolete with the introduction of torpedoes, such as Mk 35 and Mk 37, that required more complex settings.

About 1958 a new control panel (Mk 155) was introduced in the torpedo rooms to set 5 preset torpedo functions: homing mode, exploder, speed, horizontal search, and vertical search. One panel in each torpedo room. The existing control unit Mk 65-0 provided a sixth function, stratum. Some Mod 5s were later converted to Mod 14. Mod 5 is probably the version in a Peruvian submarine (ex-SS 406).

Mod 6 SSK (ASW conversions of World War II-built fleet submarines). TDC Mk 4 Mod 24 was superseded by Mod 26 and then by Mod 34 (1964). Torpedo director Mk 37 was added, then replaced by angle solver Mk 18. This version was ultimately modified to control Mk 48 torpedoes (angle solver Mk 18 Mod 4, console Mk 66 Mod 1, tone generator Mk 47 Mod 0, plotter Mk 19 Mod 1). Four forward and 4 after tubes were modified for electrical setting.

Mod 7 Tunny (SSG 282) only; this version lacked the analyzer. Only the 4 forward tubes were modified. Total weight was about 4600 lb.

Mod 8 Canceled version planned for a minelayer conversion of war-built submarines.

Mod 9 Attack teacher at New London.

Mod 10/18 For *Sailfish*-class submarine radar pickets (TDC Mk 4 Mod 10). Mod 18 is modified for wire-guided torpedo control (TDC Mk 4 Mod 37 vice Mod 28, angle solver Mk 18 Mod 3, plotter Mk 19 Mod 0); total weight approximately 4500 lb.

Mod 11 For the *Darter*, which was later fitted with Mk 101. Modified 1965 to control Mk 48 torpedoes (TDC Mk 4 Mod 39 replaced by Mod 47).

Mod 12 Wire-guided torpedo-control version, with TDC Mk 4 Mod 37 and angle solver Mk 18 Mod 4. Modified 1965 to control Mk 48 torpedoes (TDC Mod 45, angle solver Mod 5).

Mod 13 Modified 1964 to control wire-guided torpedoes (TDC Mk 4 Mod 37 vice Mod 28, angle solver Mk 18 Mod 3, plotter Mk 19 Mod 0). Total weight 5800 lb. Originated 1957. This version was redesignated Mod 17 when modified to control Mk 48 torpedoes (but see also the separate Mod 17 entry).

Mod 14/15 Modified Mod 4 and Mod 5 (1962) for wire-guided torpedoes: TDC Mk 4 Mod 36, angle solver Mk 18 Mod 3, plotter Mk 19 Mod 0. Total weight was approximately 6500 lb. Mod 14 modified to control Mk 48 torpedoes was designated Mod 18 (but see Mod 10/18 above). Mod 14 is the version in 2 Brazilian submarines (ex-SS 351 and 425) and in 2 Turkish submarines (ex-SS 344 and 346).

Mod 16 Modified Mod 5 (1964) with TDC Mk 4 Mod 40, torpedo director Mk 37 Mod 1; total weight approximately 6200 lb. This is the version on board 2 Taiwanese (ex-SS 426 and 478) and 1 Venezuelan (ex-SS 525) submarines.

Mod 17 Modified Mod 4 (1963) with TDC Mk 4 Mod 42 in place of Mod 28, and with torpedo director Mk 37 Mod 1. Total weight approximately 8500 lb. This is the version on board 1 Greek (ex-SS 365) and 5 Turkish (ex-SS 394, 402, 410, 418, and 421) submarines.

Mod 19 Modified Mod 4 or Mod 15 controlling wire-guided torpedoes (TDC Mk 4 Mod 37, angle solver Mk 18 Mod 3, plotter Mk 19 Mod 0) (1965).

Mod 20 Modified Mod 14 or Mod 16 controlling Mk 48 torpedoes (TDC Mk 4 Mod 44 or 46 vice 36 or 38, angle solver Mk 18 Mod 5 vice Mod 3). This is the version on board 1 Greek submarine (ex-SS 487).

Mod 21 Mod 18 modified to control Mk 48 torpedoes (1965): TDC Mk 4 Mod 45, angle solver Mk 18 Mod 5.

Mod 22 Mod 14 (originally Mod 14 interim) modified to control wire-guided torpedoes (TDC Mk 4 Mod 36, angle solver Mk 18 Mod 3, plotter Mk 19 Mod 0, range conversion scale Mk 1 Mod

0, 2 sub attack-course finders Mk 1 Mod 3). The last are circular slide rules used to determine whether or not a desirable firing position can be reached, add to aid in reaching that position; a pointer disc represents periscope angle. Total weight is about 6100 lb.

◆ Mk 111

This solid-state digital ASROC and torpedo FCS (using the Mk 38 attack console) was widely installed in the late 1950s and early 1960s, e.g., on board FRAM destroyers. The early digital system was considerably less reliable than the analog computer of the somewhat later Mk 114, which superseded it during the 1960s. Mk 111 could control ASROC but was not rigged to control existing Hedgehogs. Ships carrying Hedgehog, therefore, retained versions of the earlier Mk 105 described above.

Mk 111 receives target position data at discrete intervals, plus continuous inputs of own-ship course, and various manual inputs such as parallax, target depth, and curvature of target track. It computes target position, true wind, aim point, launcher train and elevation orders, time of flight, velocity at motor separation, time to airframe separation, and true polar coordinates of the weapon's water-entry point. The group includes an analog stabilizer.

Physically, Mk 111 is similar to the Mk 114 described below, with a large CRT alongside its ballistic computer; in this case the dual console is Attack Console Mk 38. The digital computer can handle ranges out to 32,000 yd, target depth to 1400 ft, and target speed to 35 kt. It can engage only 1 target at a time. The system (as opposed to computer) range limit is 35,000 yd. These are 1959 figures, but they are unlikely to have improved since. Total system weight is 2815 lb, including the 2255-lb attack console.

Mk 111 initially used a magnetic drum memory, but in 1960 BuOrd introduced new technology in the form of a 20-kbit magnetic core memory (12 kbits of which were initially used). Although this unit was originally described as insurance against the possibility of problems with the rotating drum, later it became standard. Even with its reliability problems, Mk 111 enjoyed an advantage over the analog Mk 114 because it could be reprogrammed (rather than physically changed) to accommodate the Mk 46 Mod 1 torpedo (about 1966). New operational program tapes (ORDALT 5719) provided ballistic data for the new torpedo as well as the earlier Mk 44 and the Mk 17 nuclear depth charge. However, the firing panel had to be changed physically, and the opportunity was taken to make human-factors engineering improvements to follow practice in the slightly later Mk 114 system.

Only the first 53 ASROC installations were Mk 111s. This system was planned for the *Leahy*, *Belknap*, *Bronstein*, and *Garcia* classes, but all of them were completed with Mk 114 instead. The initial (FY59 and FY60) FRAM I destroyers retained their Hedgehogs, which were controlled by Mk 105 FCSs retained alongside Mk 111.

Versions:

There was initially some confusion: Mod 1 was initially described as Mod 0 and was initially applied to the FRAM I destroyers. The designations given below are the current ones.

Mod 1 The prototype, on board the *Norfolk*, using SQS-23 sonar and Mk 56 GFCS, with the Mk 16 Mod 2 ASROC launching group and Mod 5 torpedo tubes.

Mod 2 On *Adams*-class missile destroyers (DDGs 2-15), using SQS-23 (now SQQ-23) sonar and Mk 68 GFCS, with the Mod 1 ASROC launching group and Mod 5 torpedo tubes. These ships have FCS Switchboard Mk 32 Mods 11-13 and 15. Originally, Mk 111 was planned for the entire class, but DDGs 16-24 were completed with Mk 114 instead. This designation was originally applied to at least 2 of the *Mahan* class (DLGs 11 and 15, later redesignated DDGs 42 and 46).

Mod 3 Designation canceled in 1969: it would have applied to Typhon missile cruisers (DLGN) and would have been the only version using SQS-26 sonar.

Mod 4 On *Albany*-class (CGs 10–12) missile cruisers, using SQS-23 sonar and Mk 56 GFCS, with the Mod 2 ASROC launching group and Mod 5 torpedo tubes. Mod 4 is now extinct. Unlike the *Norfolk*, these ships had Mk 56 added as an afterthought, and it was probably not integrated with Mk 111 (they were probably designed to use their missile-tracking radars to spot the fall of ASROCs).

Mod 5 The *Long Beach* (CGN 9) system, parallel to Mod 4. Unlike the *Albanys*, the *Long Beach* class had an early version of NTDS. This version incorporates FCS Switchboard Mk 32 Mod 32.

Mod 6 The *Bainbridge* (CGN 25) version, using SQS-23 (later SQQ-23) sonar and Mk 63 GFCS, with the MK 3 ASROC launching group and Mk 5 torpedo tubes. As in the cruisers, the GFCS was an afterthought, and the missile tracking radars are presumably used to spot the fall of ASROCs. This version has FCS switchboard Mk 32 Mod 14.

Mod 7 The FRAM I destroyer version, using SQS-23 sonar and Mk 37 FCS. Mk 111 survives on board the former DDs 785, 786, 788, 790 (with Mk 105 Mod 10), 826, 841 (with Mk 105), 853, 887, and 890 (with Mk 105). This version controls the Mods 1–3 ASROC launching groups and Mk 5 torpedo tubes.

Mod 8 The *Mahan* (DDG 37)-class version, using SQ-23 (now SQQ-23) sonar and Mk 68 FCS (as in the *Adams* class), controlling the Mod 1 ASROC launching group and Mod 5 and 6 torpedo tubes. This version incorporates FCS switchboard Mk 32 Mods 5 and 16.

Mod 9 Replacement for Mod 4 on board the missile cruiser *Albany*, whose SQS-23 sonar was upgraded to -23B. The *Albany* was fitted with NTDS. The original version of the ASROC launcher and the torpedo tubes were retained.

◆ Mk 113

The Librascope Mk 113 FCS was designed to operate with the BQQ-2 sonar, but versions for strategic submarines operate with their simpler sonars. Mk 113 incorporated the first submarine digital fire-control computer, Mk 130, with Mk 129 for leveling and for SUBROC missile calculations. Although the system was digital, it could control analog-set weapons, particularly SUBROC. Later versions of Mk 113 were also the first use of CRT displays in a submarine, in analyzer console Mk 78. This interactive display was intended to increase the number of targets the system could handle simultaneously. Work on a Mk 48 torpedo capability began in 1964 (improvements to Mods 2 and 5).

The main attack-center element of the Mk 113 system is an attack console consisting of an attack-control console (Mk 50), an attack director (Mk 75), and an analyzer console (Mk 51, later Mk 78). Mods 9 and 10 also have a signal-data converter, and Mod 9 has a digital interconnection box. Versions equipped to fire Mk 48 torpedoes also have a torpedo-control console (Mk 66), and a tone-signal generator (Mk 47).

Architecturally, Mk 113 was similar to Mk 101; the analog analyzer console Mk 51 was equivalent to the analyzer of the earlier system. Each console could track 1 target. The attack-control console was broadly equivalent to the position-keeper. The attack director was analogous to the angle solver of the earlier system. Unlike the earlier system, Mk 51 was designed primarily for passive operation. Its 3-point solution was based on 3 target bearings, continuously input own-ship course and speed, and 1 input of range, target speed, or target course. Alternatively, it could accept a series of discrete range/bearing combinations. In either case, like Mk 7, Mk 51 required an initial assumption that the target was following a straight or curved course.

The analog-computer attack director functions as a target position-keeper, a torpedo-order computer, and a wire-guided torpedo position-keeper and controller. It can accept data from either the analyzer or any of the sonars, and also from the ship's

navigation system. As a target position-keeper, the Mk 75 computes and displays present bearing and range, as well as bearing and range rates, using the most recent values of automatically or manually inserted bearing, range, course, and speed. As a torpedo-order generator, the angle-solver section computes gyro angle and enabling run for the electrically set torpedoes. Run depth is set manually. The angle solver also provides information to operators of wire-guided torpedoes and dead reckons the torpedo after firing. The attack director also stores the ballistics for the arsenal of preset and wire-guided torpedoes fired by the system.

Mk 113 was introduced as fully passive fire control (TMA), and therefore plotting became more important. The conning officer generally watched the developing plot but had a poor view of the analyzer console and the attack director (attack console Mk 50 was on the left, next to the analyzer console, with the attack director on the right). However, in effect the conning officer was the means of integrating the electronic and paper portions of the overall system. That integration was considered so important that the Mod 5 version (for strategic submarines) was physically rearranged (1967, ORDALT 6538) to improve the conning officer's view of the analyzer and the attack director (the attack director was repositioned between the analyzer console [on the left] and the Mk 66 control console used for Mk 48 torpedoes).

Like their predecessors, the Mk 113 consoles displayed their data on a series of dials (showing relative target and own-ship headings) and digital readouts. The heading dials were originally devised largely as a visual check of the likely accuracy of generated fire-control solutions. However, the arrangement of data suitable for the fire-control operations of the 1950s was ill-suited to the elaborate TMA of the next decade. The system did indeed collect the required data, but they were spread over numerous dials and readouts. The solution was what amounted to a "glass cockpit," in which a CRT (analyzer Mk 78 in Mk 113 Mod 9) could switch from display to display, to quickly provide a TMA team with what it needed. The same CRT could display several alternative solutions for interactive analysis.

The CRT was necessarily associated with a digital computer. TMA was particularly important for ballistic-missile submarines, and the CRT-equipped analyzer was devised for them. Its digital computer was the geoballistic computer of the Poseidon missiles the submarines carried.

In this version, the attack console contains 4 independent sections: (i) Plotter section with a CRT displaying the geometry of targets, own-ship, and either a consort vessel or wire-guided torpedoes; it also controls nonsynchronous presets. (ii) Consort tracker, which contains the displays and controls used to insert data from a consort vessel into the Poseidon computer for target analysis. (iii) Firing panel section, which displays torpedo and tube conditions and controls tube firing; it includes angular and linear spread pattern controls. (iv) Own-ship section, which receives own-ship course and speed information to convert relative to true bearings. The system has an inherent ability to accept data from a consort vessel (such as an escorting submarine) that is tracking the same target.

TMA provides location data at discrete intervals, and a position-keeper projects target position forward based on TMA estimates. These estimates are periodically compared with new TMA estimates. The analyzer operator selects a sensor system (e.g., passive sonar) and develops a target range solution, using the digital ballistic computer in the analyzer.

Analyzer data are fed to the attack-control console. It provides a geographic display (geosit) showing target, own-ship, and the dead-reckoned torpedo position(s), the last based on commands issued to the torpedoes by the torpedo director, which actually controls the wire-guided torpedo or torpedoes. The attack-control console is the decision position of the system. Torpedo-tube firing sequence and certain presets are selected at this section. The firing panel assigns the torpedo director to a tube and sets the angular or linear spread of the torpedoes. The attack-control console is also used for missile firing. Mod 2 adds Mk

48 torpedo ballistics to Mod 0 (for Mk 113 Mod 6); similarly Mod 3 adds them to Mod 1 (for Mk 113 Mod 7). Mod 4 (Mk 113 Mod 8 FCS, 1970) could keep track of 2 targets and could also be connected to a digital computer for sound-path computations. Mod 5 is a modified Mod 3 (1981) using a corrosion-resistant cooling system, for Mk 113 Mods 9 and 11, on board ballistic-missile submarines. It can be used to control Mk 48 Mods 3 and 4 torpedoes.

The attack directors are fed with own-ship and target data; they track the target and any wire-guided torpedo fired at it. These directors compute torpedo ballistics and develop control orders; they also supply data to the leveling computer (Mk 129) for SUBROC ballistic calculations. The attack-control console is the system tactical display and torpedo-room status panel.

Each torpedo-control console is assigned to a torpedo tube. Its controls (a) select 1 of 4 groups of preset tactics; (b) individually preset the trajectory mode, anti-self-homing (ASH), pre-enable speed, search speed, search mode, acoustic mode, doppler enable, ping interval, pitch angle, search depth, floor setting, ceiling setting or operational depth setting, and target mode parameters; (c) command readback of functions set into the torpedo; (d) select 1 of the 2 function memories in the console and the tone-signal generator; (e) select the most desirable laminar distance for the torpedo; (f) command changes after launch to search depth, pitch angle, pre-enable speed, search speed, acoustic mode, search mode, doppler enable, and keylock parameters; (g) check torpedo acceptance of presets; and (h) monitor continuity of guide wire after launch. All torpedo presets except gyro angle are set at this console (gyro angle is set by the attack director and monitored by the torpedo-control console). Run-to-enable is set at the director and received at the torpedo-control console for setting into the torpedo. The console has 2 memories, so it can preset 2 torpedoes.

Versions (even numbers for attack submarines, odd for strategic):

Mod 1 could track 4 targets and engage 2 simultaneously (using 2 attack directors Mk 75), 3 analyzer consoles Mk 51 Mod 0 and 1 Mk 51 Mod 1. This version also employed a leveling computer (Mk 129) for SUBROC, 1 attack console Mk 50 Mod 0, and 1 Mk 19 plotter. This was the version installed on board *Thresher*; total weight was about 10,300 lb.

Mod 2 was the production version for attack submarines (*Sturgeon* and *Permit* classes plus *Narwhal*). Principal components: 2 analyzer consoles Mk 51 Mod 0, 2 attack directors Mk 75 Mod 0, 1 attack-control console Mk 50 Mod 0, 1 digital computer Mk 130, 1 leveling computer Mk 129, and 2 plotters (1 prior to SSN 612) Mk 19. This version was limited to tracking 2 targets at a time. Total weight was about 8500 lb.

Mod 3 (not used) was limited to a single target. It was similar to Mod 2 but had 1 analyzer console Mk 51 instead of 2. Otherwise it was similar to Mod 2.

Mod 4 (not used) could track 2 targets at a time but engage 1 (because it had only a single attack director Mk 75). It was otherwise similar to Mod 2.

Mod 5 (SSBN 616 and 640 classes) was limited to a single attack director. It was designed to control torpedoes (Mks 14, 16, 27, 37, and 45), with space and weight reserved for SUBROC capability. This version used the submarine's missile fire-control computer (DGBC) for TMA. The Poseidon system required a sufficiently powerful computer, and the advantage of relying on a general-purpose digital machine was that it could be reprogrammed as TMA techniques changed. In this version the analyzer console monitored data going in and out of DGBC, selected which sonar was to supply data, and displayed measured range and bearings from that sonar. The analyzer controlled the mode of target analysis performed, i.e., bearings-only, range and bearings, constraints, etc. It also displayed the computed DGBC outputs of target bearing, range, course, and speed.

Principal components: 1 analyzer console Mk 51 Mod 2, 1

attack director Mk 75 Mod 1, 1 attack-control console Mk 50 Mod 1, 1 plotter Mk 19 Mod 1. Total weight about 4000 lb (1965).

Mod 6 is a Mod 2 altered in the submarine. It adds Mk 48 torpedo-control capability, using 2 torpedo-control consoles Mk 66-2 (early applications of MSI/LSI technology to submarines) and 2 tone-signal generators Mk 47 (1 per torpedo fired, 1 torpedo to a side). Mk 66 presets the torpedo; the tone generator provides guidance signals. The attack directors in this version are 2 Mk 75 Mod 2, each a Mod 0 with Mk 48 ballistics added. Mod 8 is a newly manufactured equivalent, for later *Sturgeon*-class submarines. Main components: 2 analyzer consoles Mk 51 Mod 3, 1 attack console Mk 50 Mod 4, attack director Mk 74 Mod 4 (also used in Mod 10).

Mod 7 is a converted Mod 5 (ORDALT 6538). Attack director Mk 75 Mod 3 replaces Mod 1, adding Mk 48 torpedo ballistics to the existing system. Control console Mk 66 Mod 0 (which can supply instructions to 1 or 2 Mk 48 torpedoes) and 1 tone generator Mk 47 are added.

Mod 9, for strategic submarines, was the first digital-display submarine FCS. It is a converted Mod 7 (with ORDALT 6857). Analyzer console Mk 78, with its 16-in circular CRT, replaces the Mk 51 target-motion analyzer of earlier versions. Mk 78 conducts and displays TMA calculations using synthetic video rather than dials. The ASW programs are executed by the main Poseidon geoballistic computer (Mk 88). The Mk 78 console contains enough digital readouts to permit operation (at reduced capability) in the event the CRT fails. The console also contains a 1024-word (24-bit word) memory unit to refresh the cursive CRT display. This FCS could control SUBROC missiles. It used attack director Mk 75 Mod 6, a modified Mod 3, which could compute and transmit weapons orders for Mk 48 Mod 3 and 4 torpedoes, and which supplies data to attack-control console Mk 50 Mod 5. Principal components: attack-control console Mk 50 Mod 3, attack director Mk 75 Mod 3, torpedo-control console Mk 66 Mod 0, tone-signal generator Mk 47 Mod 0, and plotter Mk 19 Mod 6, 7, or 8. Mod 9 was the submarine equivalent of the "glass cockpit" for aircraft, and its appearance, about 1967 (in connection with the Poseidon refits of existing strategic submarines), had considerable impact. Experience with it was the basis for the decision to go ahead with a digital attack center in the *Los Angeles* class, primarily to make better use of the only passive attack technique usable at long range, TMA.

Mod 10, for attack submarines, is an intermediate step toward the full digital Mk 117. It might almost be described as Mk 117 plus an analog element dating back to Mk 113; it lacks the direct digital interface to the digital sonar characteristic of Mk 117. Mod 10 employs 2 Mk 81 consoles (see Mk 117 below for details) but combines them with a series of older-type consoles: 2 Mk 75 position-keepers flanking a Mk 50 for weapons control. In Mk 117, all 3 are replaced by a single Mk 81. The analog consoles calculate deflection angle and pass it to the analog weapons; the 2 Mk 81 are used for TMA based on bearing-rate data passed from the sonar. Digital data are converted to analog by a system data converter Mk 73. In a Mk 117, the digital-to-analog conversion occurs between the analog weapons and the 3 Mk 81 (it is a weapons data converter). Mod 10 can track multiple targets, storing the resulting data for analysis. As in Mk 117, operators can interact with the system in real time during TMA. The computer memory allows recall of earlier target data. A sonar performance-prediction display makes for better passive range and depth estimates. There are also digital training and diagnostic aids. For the last 2 *Sturgeon*-class submarines (SSN 686-87), Mk 113 Mod 10 controls Mk 14 and Mk 37 torpedoes. For all units, it controls Mk 48 torpedoes and SUBROC and Harpoon missiles. In the last 2 *Sturgeons*, this system was installed with a single-frame UYK-7 (the *Los Angeles* class have a dual-frame UYK-7). These 2 ships also have 3 Mk 81 Mod 0 consoles (as in Mk 117, see that entry for a description). The *Los Angeles* version has 2 Mk 81. Both ver-

sions have 2 attack directors Mk 75 Mod 5 to convert analog signals and events to digital form for the digital displays, plus the usual pair of Mk 47 tone generators for Mk 48 torpedoes and Mk 66 torpedo-control consoles. This system (and its successor, Mk 117) was powerfully influenced by NTDS and used NTDS symbology in their digital displays.

Mod 11 is a modified *Mod 9* for ballistic-missile submarines. Like *Mod 9*, it uses attack director Mk 75 Mod 6.

Mod 12 is fitted for Mk 48 TELCOM guidance and incorporates 2 Mk 81 CRT consoles (see Mk 117 entry) and a Mk 87 signal data converter. *Mod 12* was developed for use with BQS-13 under a shipboard-requirements improvement program (SHRIMP) for 31 SSN 594/637-class submarines. The remaining submarines were fitted instead with *Mod 11*. Ultimately these ships were all fitted with Mk 117.

Libroscope is currently supplying new sections to Mk 78 consoles of *Mod 9* systems, including UYK-44 computers and new CRTs. These are presumably equivalent to the *Mod 12* described above. *Mod 9* was significant because it introduced CRTs into U.S. submarine FCSs. With the advent of SUBROC, submarines had to conduct TMA at much greater ranges, using their new spherical bow sonars. Much of the relevant sonar data was fed into the FCS, but it appeared on a variety of dials and could be summarized only on a plot. The digital computer within the system was already keeping track of the tactical situation. Given a more flexible display, that picture could be made more immediately available, for much more efficient plotting. This facility was particularly important for strategic submarines, which tended to depend almost entirely on their passive sensors (and which were the first U.S. submarines to receive towed arrays).

Virtually all surviving examples are on board strategic submarines. Attack submarines had their Mk 113s replaced by Mk 117s, presumably at the same time they were fitted with central computer complexes and BQQ-5 digitally steered sonars.

◆ Mk 114

This analog solid-state ASROC/torpedo FCS replaced the digital Mk 111. Mk 114 is now widely used on board U.S. frigates and cruisers, and also by navies that obtained destroyers and frigates from the United States.

The main unit is the Mk 53 attack console, located in underwater battery (UB) plot, containing the analog computer and the operating controls. It receives sonar data directly and is connected to a stabilization computer (Mk 134). It communicates with ASROC via the launcher captain's control panel (Mk 199).

An additional unit, position-keeping computer Mk 143, would have controlled surface-launched wire-guided torpedoes, which were to have been carried by many U.S. ships. This computer probably has been fitted only on board Spanish *Baleares*-class frigates, which incorporate fixed torpedo tubes in their transoms.

The attack console (Mk 53) consists of an attack plotter and a ballistic computer (Mk 134). The plotter consists of 2 dial units and the plotter proper (a 20 × 20-in CRT). The plotter screen can represent 4 × 4, 10 × 10, or 20 × 20 kyd; it displays own-ship and target positions, a weapon in flight, and a water-entry point. The screen is refreshed on each sonar sweep; because the blips are persistent, it shows (in effect) target and own-ship courses. The operator can align the cursor with the target images to read off target course and can adjust cursor length to measure target speed. This type of manual analysis was considered more accurate than computer analysis because it entailed relatively long time averages; contemporary computer solutions were unstable, and capacity was not sufficient to provide filtering. Readouts from the CRT are passed automatically to the associated ballistic computer.

Once Mk 114 has solved the relative-motion problem (i.e., is predicting submarine position), it provides rate-aided target-tracking data (position-keeping) back to the associated sonar,

providing a check on the accuracy of the solution. The predicted target position appears on the sonar PPI, and the sonar operator can use manual controls to transmit corrections back to the FCS. Without rate-aided tracking, the sonar operator would have to transmit each detection back to the Mk 114; the operator would be unable to examine other sonar contacts. However, if the rate-aided track is accurate, the operator need not continue to feed target positions back on a sweep-by-sweep basis but can investigate other contacts, in what amounts to TWS operation.

Critical attack information is set on a series of dials above the big CRT: this section also receives information automatically from the ship's own sensors (pit log, anemometers, gyro). In addition, the upper unit displays some sonar data, which can help an ASW officer decide on attack tactics.

The ballistic computer is alongside the CRT section, to the right. It includes a weapons-mode selection panel, a torpedo preset panel, and the firing panel. Dials also show attack quantities, ballistic data, and weapons-control information generated by the computer. The panel also displays ASROC weapon status.

The ballistic computer positions the launcher and sets the missiles and the torpedoes they carry. The torpedo presets are not computed data; they are manually set by the operator. They are, however, sent along the same data path as the ballistic computer outputs.

The stabilization computer translates sonar data from the rolling and pitching plane of the sonar to the horizontal plane in which the ballistic computer calculates.

In action, the plotter and the ballistic computer are separately manned, the ASW officer standing behind both operators. The ASW officer estimates target depth, usually selecting best submarine depth to avoid detection; depth has little effect on the overall solution.

Versions:

Mod 0 Early *C. F. Adams*-class missile destroyers (DDG 2–15).

Mod 1 *C. F. Adams* class (DDG 16–24) and *Leahy* class (CG 16–24), for use with a 400-cycle SQS-23 sonar, controlling ASROC and over-the-side Mk 44 and Mk 46 torpedoes. This version uses the Mk 53 *Mod 0* attack console. Total weight is approximately 2600 lb.

Mod 2 Equivalent to *Mod 1*, for FRAM I converted destroyers. It could control the DASH drone as well as ASROC and torpedoes. Total weight was approximately 2500 lb.

Mod 3 FRAM I destroyers DD 825 and 827 (former special ASW destroyers, DDE). It could control the DASH drone as well as ASROC and torpedoes. Approximate weight was 2900 lb.

Mod 4 Version for FY64 FRAM I destroyers except for DD 825 and 827, controlling DASH, ASROC, and torpedoes. Approximate weight was 2700 lb.

Mod 5 *Mitscher* class converted to missile ships, with SQS-23 sonar. It could control ASROC, lightweight torpedoes (Mk 44 and 46), and heavy torpedoes (Mk 37 *Mod 0* and 1 as well as EX-10, which became Mk 48). Provision for Mk 48 required an FCS ORDALT, which was never carried out. It incorporated computer Mk 143 as well as Mk 134. Approximate weight was 3900 lb.

Mod 6 *Mitscher* class converted to missile ships, with SQS-26 sonar. It controlled the same weapons as *Mod 5* but had 2 computers Mk 134 (plus 1 Mk 143). Approximate weight, 4050 lb.

Mod 7 For the *Bronstein* class (FF 1037 and 1038), which have SQS-26 sonars. This version controls ASROC, DASH, and lightweight torpedoes; it has 2 Mk 134 *Mod 0* and 1 Mk 134 *Mod 1* computers. Approximate weight, 3300 lb.

Mod 8 For *Garcia*-class escorts (FF 1040–45) and the experimental escort *Glover*, with 2 Mk 134 *Mod 0* and 1 Mk 143 *Mod 0* computers, controlling ASROC, DASH, lightweight torpe-

does, and torpedoes Mk 37 Mod 0 and 1 (these ships were designed with torpedo tubes in their transoms). Approximate weight, 4300 lb.

Mod 9 For *Belknap* class (CG 26 and 27) with SQS-26 sonar, to control ASROC, lightweight torpedoes, heavy torpedoes Mk 37 Mods 0 and 1, and DASH. It employs 2 Mk 134 Mod 0 and 1 Mk 143 Mod 0 computers. Approximate weight, 4600 lb. Attack console Mk 53 Mod 1, used in this system and in Mk 114 Mod 12, differs from Mod 0 in that it has a new firing panel that permits firing ASROC from a Terrier launcher (Mk 10 system). It weighs approximately 2150 lb.

Mod 10 For *Brooke* (FFG 1-3)-class escorts, with SQS-26 sonar, to control ASROC, lightweight torpedoes, heavy torpedoes Mk 37 Mod 0 and 1, and DASH, with 2 computers Mk 134 Mod 0 and 1 Mk 143 Mod 0. Approximate weight, 4300 lb.

Mod 11 For *Garcia*-class escorts (FF 1047-51), with SQS-26 sonar, using computer Mk 143 Mod 0 to control ASROC, DASH, lightweight torpedoes, and heavy torpedoes Mk 37 Mods 0 and 1; approximate weight, 4000 lb.

Mod 12 For *Belknap* class (CG 28-34) and *Truxtun* (CGN 35), with SQS-26 sonar, using computer Mk 143 (no Mk 134s) and attack console Mk 53 Mod 1 (also see Mod 9) to control ASROC, DASH, lightweight torpedoes, and heavy torpedoes Mk 37 Mods 0 and 1. Approximate weight is 4200 lb.

Mod 13 For *Brooke* class (FFG 4-6) with SQS-26 sonar, using computer Mk 143 Mod 0 (no Mk 134s), to control ASROC, DASH, lightweight torpedoes, and heavy torpedoes Mk 37 Mod 0 and 1. Approximate weight is 4000 lb.

Mod 14 For *Knox*-class escorts (FF 1052-61) with SQS-26 sonar and computer Mk 143 Mod 0 (no Mk 134s), controlling ASROC, DASH, lightweight torpedoes, and heavy torpedoes Mk 37 Mods 0 and 1 (these ships were not actually fitted with the heavy torpedo tubes).

Mod 15 For *Glover*, the experimental escort, fitted with SQS-26AX, SQA-13/SQS-35 VDS, and SQR-13 (PADLOC), to control ASROC, DASH, lightweight torpedoes, heavy torpedo Mk 37 Mod 0 (interim for Mk 46), and with provision for Mk 48. It used both Mk 134 and Mk 143 computers and included a Tactical Assignment Console and a modified Mk 53 Mod 0 attack console. Approximate weight was 4850 lb (1966).

Mod 16 For later *Knox*-class escorts (FF 1062-87), with SQS-26C and SQA-13/SQS-35 sonars, to control ASROC, lightweight torpedoes, and heavy torpedoes Mk 37 Mod 0 (interim for Mk 46), with provision for Mk 48 (which was not used). It used computer Mk 143 Mod 2 (no Mk 134) and attack console Mk 53 Mod 0. Approximate weight was 3600 lb (1966).

Mod 17 For *Forrest Sherman*-class destroyers converted to missile ships (DDG 31-34), with SQS-23A sonars, using computer Mk 134 Mod 0 (no Mk 143) to control ASROC and lightweight torpedoes; approximate weight was 2600 lb (1966).

Mod 18 For *Forrest Sherman*-class destroyers modernized for ASW, with SQS-23A and SQA-13/SQS-35 sonars, using computer Mk 134 Mod 0 (no Mk 143) to control ASROC and lightweight torpedoes. Approximate weight was 2800 lb (1966). Mod 19 was for DD 933 only, with similar sonars and equipment.

Mod 20 For modernized *Leahy*-class cruisers, with SQS-23 sonar, using attack console Mk 53 Mod 0 and computer Mk 134 Mod 0, to control ASROC, lightweight torpedoes, and DASH. Approximate weight was 2550 lb (1966).

Mod 21 For Italian missile cruisers equipped with SQS-23 sonars, controlling ASROC and lightweight torpedoes, using the Mk 53 Mod 1 attack console and computer Mk 134. Approximate weight is 3180 lb (1973).

Mod 22 For the Brazilian navy (FRAM I destroyers with SQS-23 sonar), to control ASROC and lightweight torpedoes; it uses

the Mk 53 console and the Mk 134 computer. Approximate weight is 2850 lb (1973).

Mod 23 For the *California*-class cruisers, with SQS-26 sonars, controlling ASROC and lightweight torpedoes, using attack console Mk 53 Mod 0. Approximate weight is 2500 lb (1973).

Mod 24 Mod 20 (*Leahy* class) modernized by replacement of console Mk 53 Mod 0 with modernized Mk 53 Mod 2. This is now a digital/analog system controlling ASROC and lightweight torpedoes on board *Leahy*-class cruisers. Total weight is 4375 lb (1989). The digital Mod 2 incorporates an embedded OL-335(V) Data Processing Group (an embedded UYK-44), a color CRT, and NTDS symbology. The new console weighs 1000 lb.

Mod 25 Mod 9 modernized by replacement of console Mk 53 Mod 1 with Mk 53 Mod 3, on board the missile cruiser *Josephus Daniels* (1989). This is now a digital/analog system. Total weight is 4475 lb. The digital Mod 3 console incorporates an OL-335(V) processor, a color CRT, and NTDS symbology.

Mod 26 Mod 12 modernized by replacement of console Mk 53 Mod 1 with digital Mod 3 (see Mod 25 above) for *Belknap*-class missile cruisers (CG 28-34). Total weight is 4475 lb.

Mod 27 Mod 23 modernized by replacement of console Mk 53 Mod 0 with modernized Mod 2 (see Mod 24 above) to form a digital/analog system for the *California* class. Total weight is 6075 lb (1989).

No Mod number has been assigned to the modernized FCS, using the digital Mk 53 Mod 4 attack console, projected for *Knox*-class frigates (FF 1052-98). The new console includes 2 computer processing subassemblies (CAPS and CBPS, both OL-335(V)s) and corresponding display subassemblies A and B. It has a color CRT and NTDS symbology, and it weighs about 1000 lb. Mod 4 is an upgraded Mod 2 providing additional sensor interfaces.

The shift from digital technology back to analog was made because the digital computers of the late 1950s and early 1960s were still expensive, slow, and relatively unreliable. The underwater ASW problem was well enough defined to make an analog computer attractive. As digital technology improved, it became overwhelmingly more attractive, particularly because a digital system was much easier to update to match new weapons, sensors, and target characteristics. For that reason the U.S. Navy adopted the digital Mk 116 to succeed the analog Mk 114.

◆ Mk 116

This all-digital surface-ship FCS, made by Librascope, uses the SQS-53A sonar. Unlike earlier ASW FCSs, Mk 116 uses a standard UYK-7 digital computer, for simplified logistics. Mod 1 is in *Virginia*-class cruisers and *Kidd*-class destroyers. The weapons-control panel is Mk 329 Mod 1, controlling 2 missile-setting panels (Mk 330) and a torpedo-setting panel (Mk 331). The main input is an SQS-53A, fed into the UYK-7 computer. Its output goes through a fire-control switchboard, which also feeds the sonar PPI console. Mod 1 was approved for service use in October 1980.

Mod 1 has a Computer Processing Subsystem (CPS) and a Weapons Control and Setting Subsystem (WCSS), as well as a digital fire-control switchboard and an underwater fire-control switchboard. The ASW officer (ASWO) console is a standard OJ-194/UYA-4 (as in NTDS), with a PPI that displays synthetic video, stored in PPI format. The system is run by its own UYK-7 computer, separate from that of the ship's NTDS. The associated SQS-53 sonar feeds into the digital fire-control switchboard, not directly into the CPS. The switchboard connects sonar, command/control, CPS on 1 side, WCSS on the other. Weapons-control panel (WCP) Mk 329-1 selects Mk 116-1 mode (attack, training, local test), selects weapon type and launcher (including TT barrel), and also selects search depth, search mode, or gyro angle presets for ASROC or TT torpedoes. It includes the launch key.

ASW CONTROL SYSTEM MK 116 MOD 5 PHYSICAL EQUIPMENT CONFIGURATION

USD 11

ASW control system Mk 116 Mod 5. (GE)

There are 4 target channels: 2 by sonar, 1 by command/control subsystem (NTDS), and 1 manually by the ASW officer at the ASWO console. The associated UYK-7 computer stores the target's track history, conducts TMA, and displays target symbols on the ASWO PPI. It displays track-history points. The ASW officer initiates an attack upon receiving the order from the ship's command/control system (NTDS); the order is displayed on a digital-readout panel. The order identifies the target by channel number and recommends which weapon to use. A supplemental engage order can be used to attack a second target simultaneously (one with ASROC, the other with TT). A single target is engaged remotely by the ASWO using the WCP. A second target can be engaged by TT from the ASWO console. Local mode means firing from the torpedo setting panel (TSP).

The post-firing display on the PPI shows the computed water-entry point for ASROC; the depth-charge symbol is retained and position-kept for 30 min. In a torpedo attack, by ASROC or tube, the torpedo symbol is retained and position-kept for its run time.

Normally, Mk 116 is integrated with NTDS, but there is a standby mode for use when NTDS is not operating (there is no channel 3). In this case all orders are passed verbally, and associated aircraft and helicopter drop points are relayed verbally using readouts from the ASWO console. The torpedo setting panel (TSP) is normally unmanned and is used to pass prelaunch

and launch instructions from the WCP. The TSP can be used locally for the emergency or 2-target attack mode.

As of 1975, WCSS MTBF had been tested at 1200 hr and was probably 3255 hr; average MTTR was 0.20 hr, maximum 1.08 hr.

Versions:

Mod 0 is the original version for the *Spruance* class, controlling both ship-launched weapons and a LAMPS helicopter.

Mod 1, for the *Virginia* class, differs from Mod 0 mainly in using the Mk 26 missile launching system.

Mod 2 is the version in the *Kidd* (DDG 993) class. It is Mod 1 modified to be compatible with the DDG 993 combat system.

Mod 3 is Mod 1 modified for installation on board the missile cruiser *Belknap*, replacing that ship's Mk 114. The ASROC launcher is a Mk 10 Mod 8 system rather than the ASROC box of Mod 0 ships.

Mod 4 is Mod 1 modified for Aegis ships. Total weight is 1930 lb (1977).

Mod 5 introduces computer tracking capacity, to handle multiple targets. The new SQQ-89 sensors (SQS-53B/C and SQR-19) have so much more range that a ship equipped with them will often detect several submarines simultaneously. They are suitable for active/passive fire control (plus contact management, localization, and correlation). Mod 5 was evaluated on board the *Moosebrugger*, August–November 1982. DD 965 is the lead ship for production Mod 5s. This version embodies the

USD 13

ASW control system Mk 116 Mod 7. (GE)

ASW capacity required by Operational Requirement SAS-84 (to interface with and support the improved SQS-53, SQR-19, SQQ-28, and UYQ-21). The combination was called a federated ASW combat system, and presumably it amounts to SQQ-89. Mod 5 employs a 3-bay UYK-7 computer and an OJ-452(V)/UYQ-21 acoustic display console. Total weight is 6200 lb.

Mod 6 is Mod 5 adapted to the requirements of the vertical launching system. It is introduced in CG 56, which carries vertically launched ASROC. Total weight is 5000 lb.

Mod 7 introduces the UYK-43B computer, for CG 65 and later cruisers and for *Arleigh Burke*-class destroyers. DD 978 is the lead ship for the Mod 7 computer program. DD 976 is the prototype for versions of Mod 7 for non-VLS ships (DD 963/CG 47/DDG 993 classes). There are 2 OJ-452 consoles. Total weight is 7300 lb.

Mod 8 is Mod 6 with a UYK-43B computer in place of the 3-bay UYK-7: DD 977 is the prototype. Total weight is 4700 lb.

Mod 9 is the non-VLS version of Mod 8. DD 974 is the lead ship. Total weight is 5900 lb.

Mod 10 is the non-VLS version of Mod 7. Total weight is 7600 lb.

The data below refer to Mod 5.

The system is designed to accept all the contacts (and asso-

ciated data) generated by SQS-53B, correlating them with each other and with manually entered data inputs from the CDS to generate track files with at least a 70% probability that all contacts reported back to the CDS are unique. Mk 116 aids the operator in target classification and annotates the contact range after the first tagged active contact is returned to the ASW control system.

In the passive mode, Mk 116 estimates contact range and recommends maneuvers for TMA to improve that estimate. 116 creates track files accurate enough for fire control. The test requirement is that, using up to 4 pings to determine a contact's course and speed, 116 must obtain track files of sufficient quality that the CO/TAO can determine that the threat is within active sonar range (as predicted by SIMAS, the sonar performance monitor). The attack that follows is based on active confirmation of the estimated range.

These requirements were met in the 1982 trials.

UYK-43B in Mod 7 adds integrated acoustic-performance prediction and sensor supervision.

◆ Mk 117

Mk 117 was the first all-digital FCS, begun in 1971 and tested on board *Narwhal*, for installation on board SSN 700 and later U.S. attack submarines. It was initially known as the all-digital attack center (ADAC). All sonar data are input in digital form, as are target data from other submarine sensors and own-ship data. The decision to buy all-digital systems made the analog

SUBROC missile obsolete, although there was an attempt to retain it (note Mk 117 Mod 8, below).

This system (and probably earlier U.S. submarine FCSs) is as much a command-integration as a pure fire-control device. The individual sensors all feed the central computer, which forms the integrated picture of the sea volume around the submarine, much as NTDS integrates the radar and sonar pictures around a surface ship.

The console of the ADAC consists of 3 elements side by side: 2 WCCs Mk 81, 1 attack-control console (with a control panel), and a third WCC. Each WCC incorporates a computer-driven CRT switchable between several display formats. WCC functions include multiple target track; data storage and evaluation; multiple-mode tracking; multiple (alternative) TMA solutions for single targets for high solution confidence; weapon attack evaluation; and generation of computer-recommended weapon presets based on weapon model, target solution parameters, and environmental data. The standard CRT display is divided vertically into an auxiliary readout area (alphanumerics), a tactical display area, and a lower control label area. The main area is used, for example, for TMA analysis. In the manual adaptive TMA evaluator (MATE) mode, the console is set up so that the operator can determine target course, speed, and range by trying alternatives, matching the bearings they would imply against the actual bearings measured by the sensors.

Other display formats include a full tactical picture (geosit) similar to that of NTDS or of a radar PPI.

Although this system is served by a powerful digital computer, it still bears strong marks of its analog past. For example, bearing-time recorders (waterfalls) are used as the primary sonar displays (there are 4 combinations of elevation and depression, as well as different integration periods). Target bearing rate is still often obtained by measuring the slope of the curve on a waterfall display (now, by using a strobe rather than a ruler). Similarly, the classic fire-control display, a set of dials showing target and own-ship courses (used as a visual check of the correctness of a solution), is reproduced in synthetic-video form. The sheer amount of information available in the attack center still tends to be integrated only in the minds of the operators, and this problem worsens as the number of arrays increases. New programs such as BSY-2 and SOAS (see below) address this issue. The solution is not simple because of the sheer complexity of the sonar data, and also because so much of the data is buried in noise.

The attack-control console (Mk 92) between the Mk 81s monitors the tubes and the status of their contents, displaying the type of missile or torpedo in each. Its desktop contains the firing key and the tube selector. Mk 92 can launch Mk 37 Mod 2 and Mk 48 torpedoes and Harpoon and SUBROC (Mk 117 systems Mods 2 and 3 only). A control panel (Mk 362) contains preset switches; it can set and monitor 2 torpedoes simultaneously, 1 port and 1 starboard. Presets are homing type (off, passive, active, or combination), stratum (below limit, no limit, and above limit), anticapture (set between 1 and 8), speed (low, low/medium to high, and high), and horizontal search pattern (circle left, straight, circle right, and automatic). The system also presets initial gyro angle, running depth, and enable run.

Versions:

Mod 0 For SSN 700–15, using 1 attack-control console Mk 92 Mod 0 or 2, 3 WCCs Mk 81 Mod 1 or 2, and a dual-frame (2-bay) UYK-7 computer with double density memory. This version has a weapons-data converter (digital-to-analog) Mk 82 Mod 0, 3, or 5 but lacks the leveling computer Mk 129 otherwise associated with SUBROC.

Mod 1 Backfit for SSN 594–96, 603–7, 612–15, 621, using 1 attack-control console Mk 92 Mod 2, 3 WCCs Mk 81 Mod 2, a leveling computer Mk 129 (not in Mod 0), and a dual-frame UYK-7. This version includes weapons-data converter Mk 82 Mod 2 (replaced by Mod 4 when Mk 48 torpedo TELCOM capability is installed).

Mod 2 Backfit for SSN 637–39, 646–53, 660–70, 672–77, using 1 attack-control console Mk 92 Mod 0 or 2, 3 WCCs Mk 81 Mods 1 or 2, a leveling computer Mk 129, and a dual-frame UYK-7. This version includes weapons-data converter Mk 82 Mod 1 or 2 (Mod 4 when Mk 48 torpedo TELCOM capability is installed).

Mod 3 Backfit for long-hull SSN 637-class submarines (SSN 671, 678–87) using 1 attack-control console Mk 92 Mod 0 or 2, 3 WCCs Mk 81 Mod 1 or 2, a leveling computer Mk 129 Mod 0 or 1, and a dual-frame UYK-7. This version includes weapons-data converter Mk 82 Mod 1 or 2 (Mod 4 when Mk 48 torpedo TELCOM capability is installed).

Mod 5 Replacement for Mod 1, with Tomahawk capability and a digital navigation system (DMINS). The leveling computer is deleted, and the Mk 92 console is Mod 3 or 4. For SSN 596, 604–6 and 612–15, this system directly replaced Mk 113 Mod 6. The dual-frame UYK-7 has double-density memory. This version includes weapons-data converter Mk 82 Mod 4 (for Mk 48 TELCOM torpedoes).

Mod 6 Mod 2 plus digital navigation (ESGN) for Tomahawk, for SSN 637–39, 646–53, 660–70, and 672–77. The leveling computer is deleted, and the Mk 92 console is Mod 3 or 4. The dual-frame UYK-7 has double-density memory. For SSN 637, 647, 650–53, 661, 664, 672, and 675–77 this system directly replaced Mk 113 Mod 6. This version includes weapons-data converter Mk 82 Mod 3 or 4.

Mod 7 Mod 3 plus ESGN and Tomahawk, for SSN 671 and 678–87. The leveling computer is deleted, the Mk 92 console is Mod 3 or 4, and the dual-frame UYK-7 has a double-density memory. For SSN 678, 683, and 685–87 this system directly replaced Mk 113 Mod 6 or 8. This version includes weapons-data converter Mk 82 Mod 3 or 4.

Mod 8 For new FY77 and 78 submarines (SSN 716–20), providing Sea Lance/SUBROC/Tomahawk capability and the submarine integrated attack center (SIAC) with 4 (rather than 3) Mk 81 attack consoles. This version includes weapons-data converter Mk 82 Mod 3.

◆ Mk 118

The Trident (*Ohio* class) all-digital defensive FCS is based on Mk 117 but is simplified because it controls fewer types of weapons, and also because it makes greater use of digital equipment. Mk 118 controls Mk 48 torpedoes, 3-in and 6-in countermeasures, and MOSS (mobile submarine simulators) fired from catapults in torpedo tubes. The basic control consoles are the 2 SIDs (standard information display, OJ-326(V)3/UYK) in the submarine command/control center. They perform TMA analysis of the target and generate weapons orders. Each has a single CRT, and they flank the ACC (attack-control console) Mk 92 Mod 1 (Mod 1 is similar to the Mod 0 of Mk 117 systems except that it can control countermeasures). The ACC in turn connects to the external countermeasures launchers and to the 3-in countermeasure-control and-display unit.

Either of the 2 SID operators uses the ACC to select a weapon or countermeasure and fire it. This was the first time the SID console was used in an FCS; it expanded on the capabilities of the WCC Mk 81 of FCS Mk 113–10 and FCS Mk 117 to provide an operator-interactive, digitally driven CRT display. One SID operator is primarily for TMA. The other develops orders to preset and control Mk 48 torpedoes and countermeasures. Either may view the other's display; the functions of the 2 consoles are completely interchangeable, and either can perform full fire-control functions. The system uses the bearing/range indicator (BRI) Mk 116, similar to that in FCS 117, to remotely display target-position data for the submarine commander. The associated computer is a 3-bay UYK-7 in the ship's computer complex.

At the other end of the system, in the torpedo room, the Defensive Weapon Launch Console (DWLC) consists of 2 TT

control panels flanking an unmanned weapons-launch console (WLC) Mk 96-0. This arrangement is markedly different from (and simpler than) previous torpedo-room equipment. Mk 118 eliminates most switching and analog interfaces, with fewer types of weapons and use of digital equipment (it is almost totally a digital system). Mk 96 converts digital signals from the control room consoles to analog for Mk 48 and MOSS and also replaces several other equipments, to greatly reduce cabling. The fire-control switchboard of earlier submarines is eliminated altogether. Rather than using a single firing circuit with tube-select switch, Mk 118 uses a separate circuit in each tube, with 1 control per tube in Mk 92. The weapons-select switch is eliminated because there are only 2 types, Mk 48 and MOSS. To switch a tube, the cable connecting the breech door with weapons-launch console Mk 96 is disconnected at the console and mated with a different console connector dedicated to the weapon involved. The result is only 45 cables in all, compared to over 200 in the *Lafayette* class Mk 113-9. All countermeasure launching is controlled at the Mk 92 panel, which can remotely control 3-in countermeasures.

Software is similar to that developed for Mk 113-10 and Mk 117. It processes data for multiple contacts, using various techniques for determining contact and target position and motion. Typically, it initially uses Kalman automatic sequential TMA (KAST) for a rapid estimate of relative location; the operator refines the estimate on the SID console. The options include KAST edit, manual adaptive TMA evaluation (MATE), Ekelund ranging, and depressing/elevation (angle) ranging. The SID software also provides analysis of the environment; it can show search and avoidance modes, i.e., areas favoring disclosure of a target and areas providing greatest chance of avoiding counter-detection. The software also includes evasion tactics and a system alert module.

Mk 118 is superseded in more recent Trident submarines by CCS Mk 2 Mod 3.

◆ Mk 309 Fire-Control Panel

Despite its designation, this is a compact ASW FCS. It is essentially a means of self-defense: torpedoes are fired, and the bridge is advised of the appropriate evasion course. Mk 309 receives 3 synchro inputs (target range, bearing, and own-ship course), and transmits only 1 synchro output (own-ship heading error). It also transmits torpedo presets to the torpedo tubes and displays tube/torpedo status signals.

The console does not incorporate a computer. Instead, a computer ashore was used to generate numerous situations involving a submarine and a frigate. Each was simulated to find an optimum ship evasion course, and the courses were grouped into evasion envelopes for targets at various courses and speeds. The result was a firing doctrine that could be stored in the limited memory of the Mk 309 panel. Given a situation defined by the 3 synchro inputs, Mk 309 selects the appropriate evasion envelope.

The sonar operator tracks the submarine and transmits bearing and range by synchro, providing verbal estimates of target aspect and speed; alternatively, these data are taken from the NC-2 (DRT). They are entered manually into the panel, which recalls the appropriate doctrine, transmitting a course-to-steer to the bridge. The panel also displays maximum, optimum, and minimum torpedo-firing ranges. It also recommends a lead angle. The operator enters torpedo presets and fires the weapon.

Versions: Mod 0 (75 lb) for the WHEC 715 coast guard cutters and for the Saudi *Badr*-class missile corvettes. Mod 1 (340 lb) is for the *Perry* class. The Mod 0 designation was assigned in 1968.

Other torpedo-control panels cannot operate independently; they are elements of larger underwater FCSs. Mk 264 Mod 0 is part of FCS Mk 105. It selects the Mk 32 barrel and presets initial search depth, search floor, and gyro angle. Mod 3 is part of Fire-Control Group Mk 111. Mod 2 was developed for the experimental ASW hydrofoil *High Point*. Mk 309 replaces the combination of EX-290 and panel Mk 264.

This fire-control panel is also used on board the Saudi missile corvettes (*Badr* class).

◆ CCS Mk 1

Combat-Control System Mk 1 was begun in FY73; it combines the digital Mk 117 with the submarine central-computer complex. It uses a 2-bay UYK-7 computer. Installation began with SSN 700 (backfit into SSNs 688-99). Total weight is 11,000 lb. CCS Mk 1 was approved for service use in 1980.

Mod 1 adapts Mk 117 to control Tomahawk missiles against OTH targets (based on Outlaw Shark experience) and was approved for service use in July 1980.

Mod 2 is similar to Mod 0 but supports the submarine vertical-launching system. It employs 2 UYK-44 computers and controls Mk 48 Mod 1, 3, and 4 torpedoes, Tomahawk, and Harpoon; the associated sonar is BQQ-5C. This and later versions include 3 Mk 81 Mod 2 and 1 Mk 81 Mod 3 WCCs and a Mk 92 Mod 4 attack console. The Mk 81 Mod 3 is an enhanced Mk 81 adapted to Tomahawk missile control on board *Sturgeon*- and *Los Angeles*-class submarines. It has a console data bus, a 32 bit × 32k display refresh/bulk memory, an alphanumeric keyboard, an edit capability for keyboard and list set functions, and a UYK-20 emulator for target correlation and processing. The console, therefore, has quicker responses, gains real-time access to expanded data bases on board the submarine (which are needed for Tomahawk flight planning), gains internal refresh capability, and has a reserve for future growth.

Mod 3 is Mod 2 with Mk 48 ADCAP capability, for SSN 719-25 and 750.

Mods 4 and 5 add Sea Lance capability. When installed on board *Sturgeon*-class submarines, Mod 4 can control SLMM mobile mines.

◆ CCS Mk 2

Raytheon's Combat-Control System Mk 2 is the successor to CCS Mk 1 in *Los Angeles*-class submarines. In these systems a new Common Display Console Mk 130 replaces the Mk 81 WCC and SID (situation information display) of earlier systems. It is a multifunction workstation based on the Raytheon SC-2000 series, which in turn is derived from the Silicon Graphics 4D/20 Personal IRIS Workstation. The workstation incorporates special-purpose processors to convert analog PPI data to raster-scan; to convert sonar data to LOFARgrams, waterfalls, and A-scans; and to superimpose synthetic data on raw video. The 19-in color CRT has 1280 × 1024 pixels (24 bits per pixel, refreshed at 60 frames/sec). The screen can show as many as 16 simultaneous windows. The embedded 32-bit RISC computer, which uses a VME bus, has a throughput of 8 MIPS. An associated image memory generates alphanumerics, symbols, and graphics. The earlier consoles used cursive CRTs. Outputs include 2 NTDS channels (Type H). The operator controls are variable-action switches, a programmable flat panel (with switch overlay), a keyboard, a keypad, and 4 track marbles with entry switches and label readouts. Optional features are a second CPU, a graphics processor, and bulk memory.

A Mod 1 version is used for OTH-T. It is similar to Mod 0 but adds 2 more NTDS channels (Type B). Mod 2, for Trident submarines, is similar to Mod 0 but has a 17-in monochrome CRT, Type B NTDS channels, and no keypad or track marbles. Mod 3, also for Trident submarines, is similar to Mod 0 but has a 17-in monochrome CRT, 2 additional NTDS channels (Type B), 1 trackball, 8 multifunction switches, and no keypad or flat panel display.

Probably much more important is the modular software design, which permits Raytheon to offer versions of CCS Mk 2 for all 4 current U.S. submarine types (see below). One requirement is sufficient computing power to support a powerful emulation mode, so that the workstation can replace several current consoles without any impact on existing interfaces.

The existing weapons-launch console, weapons-data converter, and TT-control panel (all located in the torpedo room) are retained (in BSY-1 they are replaced by a new weapons-

launch-system console). These systems incorporate a new submarine random-access-data storage set, SUBRASS (BYH-1), which replaces the earlier UYH-2. Submarines with vertical tubes but without BSY-1 have an additional set of Tomahawk control panels and interface consoles in a separate missile-control room (not required for Tomahawks loaded in standard torpedo tubes).

The CCS Mk 2 Tomahawk targeting subsystem is based on a UYK-44 and a parallel processor and operates 20 times faster than its CCS 1 equivalent.

Raytheon won the CCS Mk 2 contract in September 1988. The first should enter service in 1992.

CCS Mk 2 is part of a more general program to merge submarine FCSs into more comprehensive combat-control suites combining sonar operation, TMA, tactical display, weapons control, navigation, and communications.

Versions:

Mod 0 is for *Los Angeles*-class submarines without vertical launch tubes (SSNs 688-718). One UYK-44 computer of the earlier CCS Mk 1 is retained, but the previous UYK-7 computer is replaced by a UYK-43B. The former Mk 81 consoles are replaced by 4 Common Display Consoles Mk 130 Mods 0/1 (the single attack console Mk 92 Mod 5 or 6 is retained). The associated sonar is BQQ-5E(V)3, and the system is compatible with an HP 9020 (DTC I tactical decision aid) computer.

Mod 1 is for *Los Angeles*-class submarines with vertical-launch tubes (SSNs 719-25 and 750).

Mod 2 is for later *Los Angeles*-class submarines with vertical-launch tubes (SSNs 751-79). There is no attack console; instead there is a weapons-launch console (WLC) designated 2015-2020. These units are equipped with BSY-1.

Mod 3 is the SSBN version, controlling only torpedoes and countermeasures (it replaces Mk 118). Since it does not control Tomahawk and Harpoon missiles, it lacks the UYK-44 of the other versions. It has 4 new common display consoles (Mk 130 Mod 0) but retains the single attack-control console (Mk 92 Mod 1) of the earlier system. The associated sonar is BQQ-5E(V)4.

◆ Combat Control System (*Los Angeles* Class)

The *Los Angeles* was the first U.S. submarine to have a combat system built around digital computers. It employs a central computer complex (CCC) with a UYK-7 computer to conduct a variety of combat-system functions. The CCC processes attitude signals (converted into digital form). It receives raw velocity data from the inertial navigation system and computes own-ship velocity north and east. There is also an underwater log and an analog dead-reckoning analyzer/indicator (DRAI). The CCC conducts TMA using primarily sonar inputs and navigational data, under control of the FCS. The BQQ-5 sonar transmits data directly to the CCC, which then provides this information to the fire control-signal data converter (FC-SDC) for use by FCS analog devices. The BQS-15 active sonar transmits analog target data directly to the fire-control analog devices and to the CCC computer for TMA. The CCC computer combines the target and own-ship data through target localization and TMA computations and, thereby, allows ship's personnel to evaluate the tactical situation. Simultaneously with target and own-ship data entry into the CCC, the FCS digital display subsystem (DDSS) provides the computer with the operational program control necessary to perform target localization and TMA. The DDSS also provides various display techniques, such as numerical, geographic, vectorial, or tabular display and analysis, during the target localization and TMA process. Manual TMA calculations may also be performed by fire-control and sonar-system operators. These calculations are primarily performed at the navigation/sonar (NAV/SONAR) plotting station. They may also incorporate ECM bearing data and periscope range data.

When the *Los Angeles* class was conceived, it was assumed that TMA would be automated. However, it was soon discov-

ered that sonar data were always somewhat fuzzy, and that automated solutions were often misleading. Computer capacity was insufficient to allow for operator modification of a running solution, so it became standard practice to run TMA solutions by hand in parallel to the machine. Human interaction requires enormous computer capacity, which is why word-processing (perhaps the epitome of human intervention in machine operation) was entirely impractical until the early 1970s, and then only on very powerful mainframe computers. The jump in computer capacity represented by BSY-1 finally allows operator intervention on a scale sufficient to make automated TMA well worthwhile.

Classification is usually by target acoustic or electromagnetic characteristics; and BQQ-5 can conduct automatic classification. These data are routed directly to the CCC.

Weapons and tactic selection are by the weapons order subsystem (WOS), supported by the CCC computer. The system includes 2 attack directors, 2 torpedo-control consoles, 1 firing console, 1 own-ship data console, and 1 leveling computer. WOS programs the Torpedo Mk 48 for launch. The assigned attack director uses analog TMA solutions from FC-SDC to compute torpedo orders. The attack director also computes and transmits the torpedo gyro angle to the torpedo. The torpedo-control console monitors attack-director functions and generates additional preset data as required. For SUBROC, the attack director provides target parameters and own-ship data to the leveling computer. The latter processes these data and transmits ballistic preset signals to SUBROC; the leveling computer also provides prelaunch alignment signals.

The WOS firing console initiates launch of preselected weapon(s). In the case of Mk 48, WOS continues to guide the torpedo. For SUBROC, WOS provides post-launch position-keeping calculations, for evasion or re-attack.

The original CCC was installed on board SSNs 688-99; an updated version appeared on board SSN 700 and was backfitted on board earlier *Permit*/*Sturgeon*-class submarines, presumably in connection with the installation of BQQ-5.

◆ FFISTS

Frigate integrated tactical system for the *Knox* class, intermediate in capability between the current manual system and SQQ-89 (see the Surveillance and Control section for details).

◆ SOAS

GE's Submarine Operational Automation System is being developed under a 5-yr contract with DARPA awarded in February 1990. It is intended to provide a commander with a much better and much more current picture of the tactical situation, to enable quicker reaction. SOAS differs from current systems in its use of AI and knowledge-based systems to interpret and integrate sensor data. In theory, a system like SOAS is needed because passive detection ranges are shrinking, so submarines may more often suddenly encounter each other. In such circumstances, reaction time, rather than careful TMA, determines whether a submarine will survive. The recent increased emphasis on submarine torpedo countermeasures is probably motivated by the same development.

The central requirement is to improve a submarine commander's image of the tactical situation. The main sensor is passive sonar, and the problem is that the acoustic environment is extremely complex (and quite noisy). The AI approach is to develop several alternative hypothetical situations corresponding to the known acoustic data, then compare them to find the most likely. Such a comparison takes advantage of known negative information. The SOAS system may also be able to recommend specific maneuvers that can clarify the situation. The kind of computer logic that juggles several alternative hypotheses is also suited to planning with uncertainty, for example, seeking actions most likely to improve the tactical position, or the safest paths to disengagement.

Probably much of the SOAS effort will be devoted to developing the computer approach to problem solving in an uncertain environment.

AI is an obvious candidate for integrating the mass of information available to a submarine, but there is still a very real fear that a computer program may misinterpret that fairly ambiguous data. Such misinterpretation has been experienced in much simpler cases, such as calculations of sonobuoy ranges. It seems likely that SOAS was initially intended to react automatically to particularly threatening circumstances, but that the program was (or will be) ultimately scaled down to the presentation of a more integrated sensor picture, perhaps also providing tactical advice (e.g., illustrating the consequences of alternative actions). SOAS may also be able to assess the acoustic consequences (flow and other self-noise) of particular maneuvers, and to integrate that assessment into its tactical advice. It is also to assist in emergency damage control.

In theory, SOAS should make for a smaller and more effective submarine crew. The current submarine command and decision process involves about 28 people and 4 console/workstations. GE plans a command center with 4 large-screen displays: 1 for ship systems status, 1 for weapons status, 1 for command tactical planning, and 1 for command situation assessment. Sensor information would flow into the situation assessment display, which would generate a "world scene" feeding into the tactical planning position. This position would also accept platform "scene" (status) information from the ship systems status board. Plans generated at this position would be presented to a tactical executor (CO), who in turn would issue platform and weapon orders. The command and decision team would be reduced to seven: the CO, the tactical planning officer (TPO), the situation assessment officer (SAO), the ship's systems coordinator (SSC), the weapons-control coordinator (WCC), the damage-control coordinator (DCC, also responsible for signature management), and the OOD, supervising both the SCC and the WCC. SOAS would also accommodate a sonar supervisor, a radio-room officer (RRO), and an OTH operator.

Program goals are a tenfold reduction in all assurable self-signatures in tactical situations; a tenfold reduction in scene description ambiguities and errors; a fourfold reduction in reaction time in "pop-up" situations; a threefold reduction in classification time; improved classification accuracy; provision of multiple alternatives at all critical decision points; a twofold improvement in weapons effectiveness; and the possibility of using new, previously unexecutable, tactics.

GE won the SOAS contract after a 6-month competition against Martin Marietta, McDonnell Douglas, Lockheed, IBM, and Raytheon. SOAS is part of a DARPA submarine technology initiative authorized in 1988.

◆ SUBACS

See BSY-1 above.

◆ AMSP/2

EDO's Advanced Modular Signal Processor (Series II) has been adopted for SQR-18A(V)3. It is a new type of parallel processor made up of 3 hardware modules: processors (digital signal processors, DSPs), cross-bar data-transfer network, and mass-storage memory expansion. All of the elements are compatible with standard external buses and with internal VME backplanes. Each cross-bar is a bus for up to 15 devices. Each connector can be programmed to be directional (so that data flow in a direction determined by software), and data can be transferred both port-to-port and in a broadcast mode (to any N ports). Destination ports can be programmed on line.

Each processor has its own memory unit so that there is no need to switch in and out of a central (global) memory during processing. All of the elements on any 1 cross-bar effectively communicate simultaneously, and the system can change its internal relationships as it executes a problem. The entire processor communicates with other equipment via an Ethernet bus. AMSP uses a tree architecture. For example, 1 input into

a cross-bar might communicate with another 5 devices on 1 side of the next cross-bar; they communicate with another 8 on the other side, which also communicate with 7 more on the other side of the next cross-bar, and so on. In contrast to some other parallel processors, each processing element operates independently because it need not send its product directly to (or receive input directly from) any other element. This programmed flexibility makes it possible for the AMSP cross-bar network to simulate virtually any network topology.

The cross-bar communicates with each processing element (PE) at 7.2 Mbytes/sec via first-in/first-out (FIFO) buffers. They, in turn, communicate with the PE manager module at 28.8 Mbytes/sec; the module operates at 15 MIPS/30 MFLOPS and has its own PROM and RAM. The PE arithmetic processor operates at a similar speed, using its own PROM, in which signal processing or other mathematical algorithms are stored. A memory-expansion module is associated with each PE.

EDO claims that the use of a few simple modules greatly reduces both cost and technical risk. Special PC-compatible programs are available to develop the subprograms used in the PEs. AMSP was first developed as a coherent processor for the EDO 780 export sonar (1983). It was also adopted for the SQR-18A(V)1 and SQR-18(V)2. SQR-18A(V)3 will be the first production application of the new AMSP/2.

◆ Kanaris System

UNISYS is developing a new FCS for half of the Greek *Kanaris*-class submarines, in collaboration with the Hellenic Navy Research and Development Center (GETEN). The system consists of a main control console (MCC) consisting of 2 side-by-side, color, multifunction tactical modular displays (TMDs), 2 sensor peripheral units (SPUs), and 2 operator control units (CUs); plus a 2-cabinet firing distribution unit. Each combination SPU/TMD/CU has a UYK-44(V) computer embedded in it, and a channel connects the 2 computers. The TMD displays the tactical situation as well as digitized radar and sonar video. The associated control unit contains a trackball as well as manual entry buttons, e.g., for FCS data entry and also for the display of FCS status. There is also a 12 × 40-character plasma display/touch entry panel.

Sensor and other input data pass through junction boxes into the 2 SPUs, which feed the TMDs. Decisions made at the TMDs in turn are fed to the firing and distribution unit, which incorporates actual fire-control calculation.

The SPU is essentially an analog-to-digital and discrete-to-digital converter, with 24 single-speed synchro input channels, 2 linear analog-to-digital input channels, 2 single-speed synchro output channels (with growth to 6), 8 discrete inputs (with growth to 24), and 8 discrete outputs (with growth to 24). Data are provided to the UYK-44s of the TMDs via a 16-bit A-NEW bus. Radar data are provided directly to the TMDs.

Each TMD contains a 19-in color CRT (1024 × 768 pixels), with 8 memory planes for data prioritization; it is capable of displaying 8 colors or intensities for radar video. The TMD incorporates a special high-speed sequencer and 2 pages of graphics image memory for fast graphics. The value of the 2 pages is that the operator can rapidly flip between them. The TMD has separate display and graphics processors, the latter translating the former's tables into pixel data for actual display. The operator can interact with the computer by touching the screen (finger-on-glass, or FOG, operation). The associated version of UYK-44 has a 128k ROM and 256k of nonvolatile read/write memory (protected by battery backup); throughput is 800 KOPS.

The firing and distribution unit selects, presets, and guides torpedoes; it also passes firing data to the 2 missile-data processors used to fire Harpoons.

The entire system is 2-sided, for redundancy, and the FDU can operate as an independent FCS if the TMDs fail.

Basic system functions are divided into surveillance and tactical evaluation (including contact and track display, track correlation, identification, classification, prioritization, and targeting); motion analysis (including automatic tracking, interactive

tracking using graphics, and tracking solution endorsement); navigation; engagement and guidance; maneuvering (threat and own-weapon avoidance); and attack evaluation (including simulated weapon runs and action recommendation). The system tests, presets, launches, and controls 4 weapons types, presumably 3 torpedoes and Harpoon. The system will be able to control 6 torpedoes simultaneously. The Greek navy has ordered 5 systems, 1 for training and 4 for submarines.

◆ ST-50

Star array processor, the second fastest commercially available array processor, has a throughput of 50 MFLOPS (the fastest is the Star ST-100, 100 MFLOPS). Eight were sold in 1989 to NOSC San Diego, to be used in 3 real-time acoustic-signal processors, 2 on ships and 1 on land at NOSC San Diego. They are rack-mountable (19 in wide), can accommodate 2 additional interfaces, and can handle up to 64 Mbytes of memory. Presumably, ST-50 is an alternative to UYS-2 for SURTASS ship upgrades. It exemplifies the variety of commercial machines proposed as alternatives to UYS-2.

◆ Rockwell Combat System (ACS)

The combat system of the Australian Type 471 submarine was developed by RSSA (Rockwell Submarine Systems Australia). Reportedly, Rockwell is also responsible for the combat systems of the projected Israeli diesel-electric (German Type 209) submarines and *Sa'ar-V*-class corvettes. Presumably, all 3 share some of the same technology. Singer-Librascope is supplying the multifunction consoles, which are the same as those of the SFCS described below.

As in the SFCS, ACS is based on multifunction common consoles (MFCC) and 1 command-plotting (CP) console. The ESM cell is, however, separate to maintain its security. Each of the 7 MFCCs is capable of handling all combat-system functions, primarily surveillance (detection, classification, contact-data management) and threat prosecution (including review of surveillance data). Each console contains two 19-in touch-screen color CRTs. The CP, which is horizontal, has a 39-in color CRT, for tactical analysis or for reproduction of 1 of the MFCC displays. There are also 4 supplementary plasma displays, 2 for supplementary alphanumeric data, such as weapons status, and 2 used as remote presetting, testing, and control panels for the port and starboard sets of torpedo tubes.

The entire system is tied together by a Rockwell fiber-optic Expanded-Service Ship-Data Multiplexing System (ESSDMS), derived from the new U.S. Navy USQ-82(V) multiplexing system.

Reportedly, the Advanced Combat System (ACS) can detect more than 1000 targets, initiate tracks on 200, and localize 25 or more; and engagements are limited only by the nature of the torpedo tubes.

◆ SEAS/Seawitch

UNISYS's privately developed expert data-fusion systems are for ASW data analysis. Seawitch is the overall in-house program, and SEAS is a Submarine Expert Analysis System using techniques developed for Seawitch. Presumably, these prototypes represent technology being offered as part of SQQ-89(I).

Different sensors have different ranges of errors and, thus, present somewhat different pictures of the same tactical situation. Moreover, it is not always possible to determine what is happening in a complex tactical situation in which, for example, tracks cross (track identity is easily lost). Seawitch presents the operator with several different possible scenarios for actual tracks based on the variety of available data from the different sensors and on probabilities assigned to different possible interpretations of the data (e.g., alternative identifications for tracks emerging from a crossing). A multiple-hypothesis algorithm is used to determine the most probable interpretation. Seawitch can show uncertainty ellipses around the actual correlated track and also around the hypothesized track.

Data fusion becomes increasingly important as the variety of

Seawitch shows the effect of artificial intelligence in an ASW combat system. Here it presents the operator with several possible interpretations of target track data. (UNISYS)

Seawitch can present the operator with uncertainty limits (ellipses) around the alternatives it hypothesizes. (UNISYS)

available sensor inputs (e.g., sonars at different frequencies, off-board sonar data, sonobuoys) increases. Moreover, tactical decisions must be made more rapidly because targets can move very rapidly and, more important, because they can suddenly fire very high speed weapons. SEAS takes the output of Seawitch, which is a traditional plot, and analyzes the situation (using expert systems methods) to provide a list of target intents and future actions. UNISYS plans to extend the system to provide recommended actions; SEAS then becomes the UNISYS ASW Tactical-Decision Aid (ASWTDA). The company planned to test SEAS, using actual ASW data inputs, during 1989. This application of data bases to recommend action is somewhat analogous to the extension of NTDS to ACDS Block 1 described in the Surveillance and Control section.

◆ Singer-Librascope SFCS Mk I

The Librascope SFCS Mk I is a digital FCS that is in service in the Australian and Canadian navies and that is now (1988) being installed on Indian navy Type 209 submarines. The company claims that Mk I was the first all-digital SFCS. It reflects the company's experience in U.S. Navy systems such as Mk 113 (see above) and presumably reflects some U.S. Navy practice. Librascope described SFCS Mk I as closest in technology to Mk 118. In 1977 the U.S. Navy stated that SFCS Mk I had proven much less expensive than a comparable system purchased under standard DoD procurement rules.

Design objectives were automation (reduction of operators from 10 to 3), integration (all sensors can be coordinated by 1 operator using a multifunction console), improved availability, and adaptability to new weapons (torpedoes Mk 8, Mk 23, and Mk 48-3). The system uses computers to perform TMA and to

Librascope's SFCS Mk 1 consoles, showing an active sonar B-scan at left and a tactical summary plot (PPI) at right. (Librascope)

Elements of Librascope's SFCS Mk 1 Mod 0, including the tactical plotter. (Librascope)

generate firing orders. It can detect 20 targets, track 4, and engage 2. The 3 manned positions are the command-display console in the control room (which must be manned continuously) and the 2 fire-control consoles, each with its own CRT. The latter are manned only in action and standby conditions. Normally, 1 of the fire-control consoles provides contact motion analysis, the other controlling weapons and TT status. Input into these consoles is by both light pen and keyboard.

The system is based on a command-display console. It contains a sensor-data converter (SDC) that accepts data from 15 sensors and that has 9 passive sonar tracking channels. The display itself is a 20×24 -in paper plotter. Sonar operators can designate sonar bearings by means of 1 of the 3 sonar-assignment units at each sonar console, or the operator may designate 1 of the 9 sonar-data channels. Such designation causes the system to store all data from that channel (for the most recent 30 min) in the computer's memory. Any 4 of the 9 channels may be designated threats and, therefore, be subject to TMA. Typically a tactical analyst at the CRT of a fire-control console carries out threat assessment (e.g., TMA), normally at the right-hand console (with the left-hand console—which is functionally interchangeable—reserved for weapons control).

For TMA, passive sonar measurements are sampled every second and averaged over 20-sec intervals. The submarine can maneuver to improve TMA ranging, and both automatic and manual target solutions can be obtained. There is also an acoustic environment display (ray-path predictor).

The basic computer is UYK-20 (64k, 16-bit words, 1.3-MHz clock rate, with a 400k hard disk, average access time 18.4 msec).

Claimed MTBF is 400 hr (98% on-line availability).

Before the merger of Librascope into Singer, this system was called LFCS Mk I (Librascope submarine fire-control system Mk I). Development began after Librascope won a design competition in September 1974. The first system was delivered in mid-1978. SFCS I was also supplied to the Canadian navy, to modernize Canadian *Oberons*.

◆ Singer-Librascope SCCS Mk II

Submarine combat-control system Mk II is a developed SFCS Mk I. SCCS Mk II consists of up to 8 multifunction consoles

Librascope's multifunction console for SFCs Mk 2 (which uses 3 of them). (Librascope)

fed by a 5-MHz fiber-optic combat data bus, a single command (summary) display, a sensor-data converter/processor, and a weapons-data converter/processor. The system is federated: all processing associated with the sensor-data converter/processor is carried out in that unit. Each combat-control display has 2 separate screens: an upper plasma screen with an IR touch overlay and a lower 19-in CRT with a light pen. The display also includes a keyboard and a joystick. The summary display is identical with the plasma display of the combat-control console.

Because all the control consoles share the same data stream (which includes data from all available sensors and from any data link to which the submarine can have access), individual operators can be assigned to concentrate either on particular targets or on overall surveillance. All sensor data are automatically entered into a combat data base for processing and recording. For example, data can be selected for up to 25 simultaneous target-motion analyses.

Four targets can be engaged simultaneously with wire-guided torpedoes, and the system can also support submarine-launched missiles such as Sub-Harpoon.

All elements of the system are sized to fit through a standard 650-mm hatch, so existing submarines can be upgraded with the system without having their hulls opened.

Singer-Librascope's work on the Australian submarine combat system (in collaboration with Thomson-CSF and Rockwell International) is based on SCCS Mk II. The Australian project began late in 1985.

Librascope considers the Australian system Mk III. Mk I was the Australian/Canadian system; Mk I+ was the Indian system. Mk II was an abortive system proposed to Israel. Mk III+ was a system proposed to Canada for the abortive Canadian nuclear-submarine program. It will presumably be revived as a possibility for the diesel submarines that Canada will probably buy.

SUBMARINE PERISCOPES

Although they are not ASW sensors, submarine periscopes seem most naturally to belong in this section since they are among the sensors feeding most submarine combat systems. Because sonar may be limited in its ability to detect and track surface craft, periscopes are often the submarine's primary surface-search sensors. They are changing radically. Until the last decade, all were optical, and most submarines had 2 types, a wide-angle search periscope and a narrow-angle attack scope, the latter intended to leave the narrowest possible wake so as not to reveal too easily the position of the submarine. A submarine commander would obtain the surface picture by making a quick sweep with the search periscope, the duration of the sweep determining both the quality of that picture and the extent to which the commander exposed the submarine to detection. Much of the submarine officer's training (e.g., in the British "perishers" course) was devoted to the ability to form a coherent surface picture after the briefest sweep.
